Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

+ *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
+ *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
+ *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.
+ *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.

Über Google Buchsuche

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter `http://books.google.com` durchsuchen.

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

CLINICAL LECTURES.

TITLES.

Adhesions, intra-abdominal, E. Percy Paton, 30
Cancer of the rectum, R. Atkinson Stoney, 302
Carcinoma of great intestine, treatment of, Seton Pringle, 56
Deformities of the foot associated with abduction, Edred M. Corner, 516
Disorders of sleep, Dr. Purves Stewart, 82
Epilepsy, traumatic, treated by operation, Thomas Sinclair, 488
Exophthalmic goitre and myxœdema, R. W. Philip, 598
Eye, congenital anomalies of, Sydney Stephenson, 328, 356
Fractures at the wrist, D'Arcy Power, 656
High blood pressure, some of the organic consequences of, Dr. Leonard Williams, 6
Infantile diarrhœa, Dr. G. F. Still, 212
Laceration of the female perineum, consequences and treatment of, Dr. R. J. Kinkead, 188
Lingering labour, Dr. James Morrison, 570
Liver, enlargements of, Dr. W. Hale White, 408
Otosclerosis, Macleod Yearsley, 628
Ovaries, belated, value and fate of, J. Bland-Sutton, 108
Puerperium, prevention of fever in, Dr. H. O. Nicholson, 462
Serum treatment of typhoid fever Dr. Chantemesse, 682
Sphygmomanometer in medicine, Dr. R. Saundby, 382
Tabes, abortive forms of, Prof. F. Raymond, 236
Treatment of the insane, Dr. G. H. Savage, 164
Treatment of suppurative otitis, Dr. R. H. Woods, 138
Tubercular diseases of the knee-joint, &c., R. L. Swan, 542
Uræmic meningitis, Prof. R. Lepine, 436

AUTHORS.

Bland-Sutton, belated ovaries, 108
Chantemesse, Dr., serum treatment of typhoid fever, 682
Corner, Edred M., deformities of the foot, 516
Kinkead, R. J., female perineum, laceration of, 188
Lepine, Prof. R., uræmic meningitis, 436
Morrison, Dr. James, lingering labour, 570
Nicholson, Dr. H. D., puerperium, prevention of fever in, 462
Paton, E. Percy, abdominal adhesions, 30
Philip, Dr. R. W., exophthalmic goitre and myxœdema, 598
Power, D'Arcy, fractures at the wrist, 656
Pringle, Seton, carcinoma of great intestine, 56
Raymond, Prof., tabes, 236
Saundby, Dr. R., sphygmomanometer in medicine, 382
Savage, G. H., treatment of the insane, 164
Sinclair, Thomas, traumatic epilepsy treated by operation, 488
Stewart, Purves, disorders of sleep, 82
Stephenson, Sydney, congenital anomalies of the eye, 328, 356
Still, Dr. G. F., Infantile diarrhœa, 212
Stoney, R. Atkinson, cancer of the rectum, 302
Swan, R. L., Tubercular diseases of the knee-joint, &c., 542
White, Dr. W. Hale, enlargements of the liver, 408
Williams, Leonard, high blood pressure, 6
Woods, R. H., suppurative otitis, 138
Yearsley, Macleod, otosclerosis, 628

CLINICAL RECORDS.

Acute nephritis and scarlatina, 390
Belfast Hospital for Children, cases, 663
Cyst of the clitoris, 90
Fibro-myoma of the vagina, 89
Ovaries and vermiform appendix, malignant disease of, 118
"Siamese twins," case of birth of, 38

CORRESPONDENCE—FOREIGN.

Austria—
  Aggression and toxin, 122
  Angioma arteriale racemosum, 669
  Aorta, obliteration of, 392
  Atoxyl and syphilis, 42
  Atoxyl in relapsing fever, 420
  Balantidium coli, typus malmsten, 367
  Bier's suction treatment, 696
  Bigemina, spontaneous, 313
  Cancer, origin of, 421
  Cardia-carcinoma of the stomach, 66
  Cardiac insufficiency, 585
  Cataracta complicata, 17
  Caustic soda, erosions from, 121
  Cerebellar tumour, 641
  Circulation, physiological and pathological, 17
  Cirrhose bronzée, 585
  Cirrhosis, experimental and tubercle, 150
  Collum anatomicum humeri, 223
  Concurrent antagonistic bodies, 313
  Congenital cerebral motor defects, 249
  Cranio-plastic operations, 669
  Crystal, curious, 421
  Diagnosis of cerebro-spinal meningitis, 366
  Displacement, abnormal, 641
  Embolism of pulmonary artery, 696
  Female structure, 421
  Fistula gastrocolica, 615
  Foreign body in trachea, 615
  Gall-stone colic, 121
  Giant growth, a, 556
  Glaucoma, 529
  Hæmatoma, traumatic, 615
  Hernia, radical cure of, 393
  Hirschsprung's disease, 43
  Hypertrichosis, 556
  Hypoplasia of the aortic system, 585
  Icterus, pleiochromic, 294
  Inguinal glands and tubercle, 150,
  Injury to the neck with paralysis, 199
  Ischialgia and infiltration, 696
  Lead poionning, 696
  Lipoid, bactericide, 248
  Lipomatosis, 122
  Loew, Dr. Anton, death of, 367
  Lymph and glycosuria, 669
  Lymphatic leucocythæmia, 392
  Monoplegia, simulated, 94
  Meningococci serum, 174
  Mental moral weakness, 313
  Mongoloid idiocy, 392
  Necrosis of bone, 556
  Optic aphasia, 585
  Osteopathy, 640
  Pancreas, a new function of, 199
  Paralysis, stationary, 313
  Pemphigus contagiosus, 669
  Perl-cyst, 615
  Pes varus, 17
  Phosphorus necrosis, 223
  Physiological lines on nails, 150
  Poliomyelitis, 641
  Politzer, retirement of Professor, 475
  Polyneuritis and bacterium coli, 420
  Quadrigemina region, disease in, 174
  Radiation and necrosis, 555
  Radio-therapy of the ischias, 669
  Scapular rhombus, 17
  Sclerosis, multiple, and urinary trouble, 585
  Spondylitis infectiosa, 42
  Squint, hereditary, 249
  Stomach, contractional phenomenon of, 66
  Stomach, histological changes of, 121
  Swimmers and albuminuria, 342
  Syphilis and valvular disease, 615
  Tænia cucumerina, 669
  Tar and nephritis, 150
  Therapeutics, cerebro-spinal, 314
  Thrombosis arteriæ vertebralis, 94
  Tubal pregnancy with melena, 342
  Tubercle, diagnosis of, 43
  Tuberculosis, 448, 500, 530
  Ureters, cystic, widening of, 17
  Uterus, carcinomatous, extirpation of, 223
  Vaccination, secondary, 174, 556

France—
  Abortion, 247
  Adenitis, cervical, 311
  Apoplexy, 341
  Anglo-American Medical Society, the Continental, 498
  Artificial abscess, 554, 614
  Asthma and atropine, 640
  Bier, the method of, 221
  Broncho-pneumonia in young children, 554
  Cancer of the stomach, origin and treatment of, 447
  Colloidal silver, 639
  Coryza in infants, 366
  Diazo-reaction, 341
  Dilatation of the stomach, 419
  Diphtheria, paralysis of, 65
  Drainage in gynæcology, 365
  Exophthalmic goitre, 173, 197
  Gastric ulcer, treatment of, 583
  Gonorrhœa, treatment of, 391
  Hæmoptysis, treatment of, 584
  Hyperæmia of the pharynx, 391
  Infantile eczema, 16
  Intertrigo in the adult, 222
  Malpraxis, sued for, 120
  Metritis, treatment of, 41, 65
  Mushroom poisoning, 366
  Obesity, 293

- Œdema, acute, o the lungs, 498

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXV. WEDNESDAY, JULY 3, 1907. No. 1

NOTES AND COMMENTS.

Lord Lister and the City.

THE presentation of the Freedom of the City of London to Lord Lister last Friday cannot but give rise to some reflections on the position which the representatives of medical science hold in the estimation of their contemporaries. Lord Lister is well over eighty years of age; for twenty-five years he has been recognised all over the civilised world as the greatest benefactor to humanity that this age, or perhaps any age, has produced; he has been honoured in every civilised country by the conferment of such dignities as each could bestow; moreover his eminence is only surpassed by his modesty, his disinterestedness, and his sterling honesty. It is no exaggeration to say that for a quarter of a century Lord Lister has been the worthiest and most distinguished British subject in the kingdom, and he may fairly be claimed as a Londoner to boot. In his brief and modest speech on receiving the freedom Lord Lister spoke of it as "the highest civic honour in the world," and though medical men are duly grateful to the City for having bestowed it on Lord Lister, they cannot but wonder how it is that it has so long been withheld, and whether it would have been granted at all but for the fact that a medical man who believes in his own profession is Senior Sheriff for the year. Every year the freedom of the City is conferred on some Royal person, often from some quite second-rate country and from the point of view of humanity quite undistinguished, or on some victorious admiral or general who has doubtless rendered great service to his country, but whose achievement will frequently not be deemed of sufficient magnitude to require mention in a history-book of a hundred years hence, or on some person whose exploits are making good "copy" for the newspapers of the moment. On such occasions the streets are lined with troops, flags and banners adorn every building on the route, and all the most distinguished officers of the State are assembled to welcome the hero.

Science and British Citizenship.

ON Friday a bare handful of gentlemen, mostly medical men, assembled in the Guildhall to receive Lord Lister, there were no soldiers, and we are bound to believe that not ten persons in the City knew that any unusual event was toward. Most of the newspapers considered half a column on an inside sheet sufficient to record the event. Thus shall be done to the man whom the world delighteth to honour! There is no gainsaying the fact that in America and on the Continent Lister is a name to conjure with, and we believe if a vote were taken as to who was the greatest living Englishman, he would be easily first; yet in his own country in his old age he is fobbed off with semi-private presentation of the Freedom of the City without a cheer from his fellow citizens in the streets. It is true that Lister is the first and only medical man on whom a peerage has been conferred, but that peerage is only a barony, whilst a politician, soldier, or wealthy brewer will often despise anything below a Viscountcy or Earldom; and the bare idea of a public pension or money grant, such as the politician or soldier receives, and the brewer does not need, would raise a smile. But perhaps the truest honour and highest reward is for a man to be loved, respected and unenvied by those of his own calling, and Lord Lister has passed through the storm of controversy to the haven of honoured old age, enshrined in the hearts of medical men as their worthiest and noblest comrade. Perhaps for that reason they would wish all the more for his name to be a household word and his portrait a household possession throughout the land.

The Evans Brothers.

THE carpenter cancer-"curing" brothers at Cardigan continue to attract an enormous number of patients, and from accounts it appears that the lodgings in the town are full of sufferers seeking the aid that has been so widely advertised. Indeed, in a letter which would be comic but for the underlying pathos of the circumstances, the Evans have addressed the public through the Press asking patients not to come without special appointment, as they have already more work than they can adequately cope with. They say, "We find it impossible to give proper attention to the large number under our care. . . . This is a great disadvantage to us, and seriously injurious to those who are ill." One special correspondent reports that probably over five hundred patients are already being dealt with, so that we may safely conclude that a pretty good thing is being made out of this "secret." It seems that cancer is not the only disease to which the method is applied, for not only are scirrhous carcinomas of the breast and epitheliomas of the face reported,

259525

but lupus, necrosis of the nasal bones, and (save the mark!) polypus of the nose are specifically noted. The treatment, however, seems to be the same for all. Some of the "secret" fluid is painted on to the diseased part, an application of fresh leaves applied, and a dressing placed over all. These wonder-working brethren describe themselves as "herbalists," but it would not be a very hazardous guess to assert that this mysterious fluid contains arsenic as a prominent ingredient. The arsenical treatment of external cancer is always cropping up in one form or another, and the improvement which follows the separation of the slough produced by the caustic has been the stock-in-trade of cancer-quacks innumerable. From the published accounts it seems that the patients are not so universally satisfied as was at one time given out. That is as might be expected; the denouement in these matters is seldom as sudden as in a play.

Doctors as Dictators.

A curious but not unsympathetic article on "Doctors as Dictators" appeared in *The New Age*, a Socialist organ, last week. Indeed we may congratulate the writer on possessing a considerable amount of acumen and some working knowledge of the conditions of medical practice. It may not be flattering to us to be told that "essentially the doctor nowadays is an upper servant," but as the writer wishes to deliver us from this thraldom he at least deserves the gratitude of those who groan in the bondage of their masters. But what we are glad to learn is that Socialists have no quarrel with medicine or medical men, but rather that they acknowledge the benefits of medical science and would like to promote them. At the same time they consider that scientific merit and personal worth are only factors in a practitioner's success, and that his advice has to be adapted to the whim and social position of the patient. The writer in *The New Age* considers that the cry of "Doctors as Dictators" is a bogie, and that on the contrary the doctor is very much dictated to by the State and by his circumstances and patients. We may say with little hesitation that if the Socialists would release the profession from the painful necessity of having to do as they are bid, and would allow them to act on the scientific ideal in all cases, they would achieve immense popularity with the profession, but till old things are passed away and a new age is firmly established, we fear that men will still have their weaknesses and failings, and these will continue to cause the doctor frequently to subordinate his theoretical ideal to the practicabilities of the situation.

Livingstone College.

We publish in another column a letter from Dr. Charles F. Harford, Principal of Livingstone Medical College, commenting on some remarks in The Medical Press and Circular of June 19th, with regard to that institution. While cordially appreciating the tone of Dr. Harford's letter, and sympathetically entering into the difficulties of the position, we still feel inclined to repeat what we then said, namely, "That we find it difficult to recommend a system of unqualified practice among natives which we would condemn if pursued at home, and we notice from the report that some of the Livingstone alumni seem to practise quite extensively." We gladly accept the statement that students at the College sign a declaration that they will not represent themselves as medical missionaries or assume the position of qualified medical men; that is certainly as it should be, but does the child of nature draw the line very accurately between registered and unregistered practitioners? The only logical solution of the difficulty would be for all missionaries to be medical men, or to act only as assistants to a medical man; but presumably that is an ideal which the Church Missionary Society cannot practically fulfil at the moment. Still it is the one that should be aimed at, and if Livingstone College marks a transition in that direction, we should not be so churlish as not to wish it God-speed.

LEADING ARTICLES.

LORD LISTER AND THE FREEDOM OF THE CITY OF LONDON.

On Friday last, June 28th, Lord Lister was formally presented with the Freedom of the City of London in the ancient and historic Guildhall. The auspicious event took place, with appropriate ceremony, in the midst of an assemblage of distinguished men. The scroll of the freedom was enclosed in a gold casket of elaborate design, surmounted by a figure of Hygeia, and having at opposite ends of the base two figures, one representing London offering the scroll of freedom, and the other symbolising medical science holding out the torch of Fame. In making the presentation the City Chamberlain, Sir Joseph Dimsdale, remarked that Lord Lister, by blending the antiseptic treatment with modern surgery, had made possible what previously seemed impossible. In acknowledging the presentation Lord Lister said simply that the work in which it had been his great privilege to be engaged had brought its own reward. At the end of a brief speech he made a pathetic allusion to the consideration of the Court which permitted him to attend at his own convenience. Had it been otherwise the state of his health would have prevented his personal acceptance of their gift in that historic building. Of all the great events that have been dignified in this centre of English history it may be questioned if any more worthy of civic and national honour has ever been celebrated therein. Unquestionably Lister's name will be for ever one of the greatest and most revered in the world of medicine. The Corporation of London may be congratulated upon their action in conferring the highest dignity within their power upon the man who has probably done more than any single man for the advance of medical science and the relief of suffering humanity.

DEATHS UNDER ANÆSTHETICS.

The question of deaths under anæsthetics has vexed the minds of medical men ever since the introduction of the great boon of general anæsthesia. As years go by and experience accumulates, the conclusion appears to be more and more inevitable that there must always be an unavoidable margin of accompanying fatalities. True, some drugs used for the purpose are less dangerous than others, but, unfortunately, the safer ones are otherwise unsuitable for any but minor operations, while not a single one is absolutely safe. Yet it would be contrary to the spirit that animates the student of modern scientific medicine were he to accept the position as one incapable of further improvement. On the contrary, he is bringing to bear upon the problem every ray of light that may be obtained from the chemist, the physiologist, the pathologist, the surgeon, the anæsthetist, or from any other available quarter. Recently the introduction of spinal anæsthesia has opened up a novel departure in this highly technical branch of work, and it may even be that the final solution will be found somewhere in that direction. Meanwhile it seems not altogether impossible, in the light of recent enquiries, that some additions to our knowledge of fatal anæsthesia may be gathered from a systematic examination of all cases on certain clear and well-defined lines. The Coroner of the City of London, Dr. F. J. Waldo, has recently paid a great deal of attention to enquiries of this kind, and has gathered a mass of information that cannot fail to be of interest, and may possibly prove of real value. By drawing up exhaustive tables of the proportion of deaths to administrations under various anæsthetics, it is possible to compare the accompanying conditions. It seems to be a fact that with a given anæsthetic there are proportionately more deaths in one institution than in another. By investigation there is an obvious possibility that contributory causes may be detected in the peculiar conditions of the administrations where the greater fatality exists. One particular point worthy of careful enquiry is the exact chemical composition and source of origin, as well as cost, of each anæsthetic drug or combination of drugs. For some reason or other this aspect of anæsthetics has never been as fully dealt with as its importance certainly appears to demand. The matter, of course, touches delicate ground and would have to be dealt with tactfully. If handled without due caution, a serious injury might inadvertently be inflicted upon this or that medical charity. We should decline to believe, however, that such a suggestion would for a moment prevent any great modern hospital from lending its utmost aid to any enquiry that might help to lessen in any way the sum total of deaths under anæsthesia. There is no apparent reason, for that matter, why all enquiries should not be strictly impersonal. The statistics could be drawn up readily enough without giving the name of any institution, by resorting to the simple artifice of reference numbers. So important is an investigation of the sort to the welfare of the community that we would suggest a Governmental enquiry by a competent scientific body as a proposition requiring little argument in favour of its desirability. To avoid so plain a duty in deference to timid or hostile interests would be to reverse the outspoken and fearless candour which is one of the chief characteristics, as it is the foundation, of progressive medical science.

CURRENT TOPICS.

The Long Hours of Railwaymen.

It is an old story that many railway accidents are directly due to the fatigue of over-worked servants. This fact has been once again emphasised in a White Paper issued last week by the Board of Trade. Since the year 1900 there were thirty-four such accidents, five of them being in Ireland. A particularly bad record comes from Goole, where four accidents took place, involving the death of one railway servant and injury to three others. In the first instance a shunter was killed after working 14½ hours continuously. In the three injuries the men had been on duty 13½, 14¼ and 16 hours respectively. A fireman killed at Clapham Junction had worked 17½ hours. The record number of hours appears to have been that of a platelayer killed at Nottingham, who had worked 23¼ out of 30¼ hours, when he was run over and killed. A collision between two passenger trains at Broad Street, London, in 1904, was due to the mistake of a signalman who had been on duty 12 hours daily for the three preceding days. The whole matter is one that urgently demands legislative action in the interests both of the railwaymen and of the travelling public. As a plain statement of fact the economic loss must necessarily fall, in the long run, upon the community from whom the railway companies draw their revenues, including that portion which has to be paid away as compensation for accidents and fatalities. Clearly the public that thus pays the piper should be entitled to a voice in the conditions of employment that have been shown to be fraught with such disastrous consequences.

The Prime Minister and the Royal Commission on Cancer.

Medical officialism has again prevailed against medical opinion. In the House of Commons last week, the Prime Minister in reply to a question asking for the appointment of a Royal Commission on cancer, said "he had made inquiries of the authorities who were best qualified to express an opinion, and he was advised that it would not be expedient at present to recommend the appointment of a Royal Commission to inquire into the causes of the disease . . . and he was advised that much remained to be done before any facts could be brought before a Royal Commission with any likelihood of their making such an inquiry fruitful for the public advantage." In formulating this reply reference was made to the Imperial Cancer Research Fund ; it is therefore not difficult to infer that the "authorities who were best qualified to express an opinion," implied the Executive of this Fund, and that the strange opinion expressed by the Prime Minister on this matter was due to them. The opinion certainly was an extraordinary one, on the face of the evidence which has guided the profession generally in arriving at the conviction that such an inquiry would, as the Medical Press and Circular stated last week, prove "of enormous educative value." The force of circumstances, however, having placed the Imperial Cancer Research Fund in the position of arbiter, as between the profession, the public, and the Government of the day, it is only due to those who subscribe to the Fund to be informed upon what grounds the Executive of the Fund have advised the present Government that an inquiry is unnecessary. Doubtless, having practically been appointed arbiters, the Fund are waiting to substantiate their position as such, and this view of the case is more than likely to be the correct one, seeing that the Fund have been singularly neglectful in showing what they have done in advancing our knowledge of the disease. The fitful outbursts of cancer "booms" in the lay press are simply due to the lordly scientific silence which the Fund persists in observing whenever any matters regarding the disease obviously demand official refutation. Lay editors would hardly dare to continue to publish "facts" about cancer after having been officially informed that such "facts" were merely impossible creations, and not worthy of credence. Before long, however, public opinion will demand a Cancer Inquiry; already the lay press are beginning to direct attention to its necessity, and then "those best qualified to express an opinion" against it will find themselves powerless to resist the demand. Thus will Nemesis fall upon them for failing to recognise in the past that they have a duty to discharge towards the public in correcting statements in the Press which to the medical man are obviously inaccurate.

The Teaching of Hygiene in Elementary Schools.

The reply of Mr. McKenna to the deputation which waited on him recently in reference to the above subject was, like replies given on other occasions by his predecessors, sympathetic but noncommittal. The deputation urged the importance of giving instruction to children in the subjects of hygiene and temperance, of training teachers in these subjects, and of their being reported on by H.M. Inspectors of Schools. Mr. McKenna declared himself in full agreement with the desires of the deputation, but he confessed himself unable at present to find means of carrying them into effect. He hoped, however, that after hearing the views to be put forward at the International Conference in August, he might be in a position to suggest a solution of the difficulties. We confess we cannot see that the obstacles are so great as they appear to the official mind. It is true that the teachers must themselves be instructed before they begin to teach the children, but this could easily be done in a few carefully planned holiday courses. Within the course of a few years, the Department of Technical Instruction in Ireland has found it possible to train a sufficient staff of teachers in experimental and natural science, not for the primary but for the secondary schools of Ireland. The task facing Mr. McKenna is by no means more difficult. His complaints, too, as to the difficulty of compiling a syllabus for instruction in hygiene seems like making a mountain of a mole-hill. It was unfortunate that Mr. McKenna should have been ruffled by what he considered the "peremptory" manner adopted by some of the members of the deputation.

The Housing Problem in Ireland.

Of the many problems facing the sanitary reformer in our cities and towns, one of the most urgent is that of providing proper housing for the poorer classes. It stands, indeed, in the forefront of many questions intimately dependent on it. In the struggle against tuberculosis, in the battle against intemperance, in the extermination of all filth diseases, the providing of proper housing is all-important. In dealing with the question, economic as well as sanitary considerations have weight, and some method must be found by which houses in large numbers can be supplied without an economic loss. In the discussion on the subject at the meeting of the Royal Sanitary Institute in Dublin last week, two ways of finding a solution were put forward. Either large blocks must be erected in the heart of great cities, or improved communication with the suburbs must be established, so as to permit of cottages being built on cheaper sites. The latter plan has many points in its favour. It is more economical, in that land can be bought at cheaper rates, and it has the further advantage that the cottages can be placed in healthy surroundings where their inhabitants can have the benefit of fresh air and sunlight. It has the drawback that it takes workmen to a distance from their work and puts them to the expense of a tram or rail journey morning and evening. With improved means of conveyance, however, it is to be hoped that the chief of these inconveniences may disappear.

The King Edward Fund Bill.

On Monday, July 2nd, the King Edward Hospital Fund Bill passed the Commons.. The amendment brought forward by Dr. Rutherford in favour of representative control was ultimately withdrawn under strong pressure from high quarters on both sides of the House. As a matter of fact, the original Bill has been considerably altered since attention was first publicly drawn by the medical journals to its autocratic constitution. The Prime Minister reminded the House that the Council of the Fund included the Lords-Lieutenant of London and Middlesex, the Bishops of London, Southwark, Westminster, the President of the Free Churches, the Chief Rabbi, Chairman L.C.C., Governor of the Bank of England, and the Presidents of the Royal College of Physicians and Surgeons. It will be noted that the main mass of the medical profession, the hospitals and the public are unrepresented. Above all, the small hospitals, who already complain of injustice at the hands of the Funds, are without a single representative. Under these circumstances the Fund can hardly wonder if it has occasionally to face the fires of searching criticism.

The Housing Reform Congress.

For the first time in history the International Congress on Housing Reform will meet in the United Kingdom. It is to be hoped that the great gathering to be held in London early in August will do something to educate the nation generally upon a matter so vital to their well-being. It seems probable that in no country in the world does the jerry-builder flourish with greater impunity than in our own long-suffering realm. The absence of stringent building acts from our Statute book constitutes a standing reproach to a nation that prides itself on its practical handling of public health matters. Over the whole face of the land houses are springing up like multitudinous mushrooms in the suburbs of towns, both small and great. A brief inspection of these speculative dwellings will reveal the fact that they are more or less riddled with appalling structural and sanitary defects. Of late it has been the fashion to raise sensational outcries on the question of impure food. Clearly, however, the provision of sound and sanitary housing is of no less importance to the sturdiness of our race. Let us hope that the forthcoming Conference will teach the man in the street what the law should empower him to demand from his landlord.

Bacteria and the Tram-ticket.

The public mind is being agitated at the moment about the possible dangers to health incurred by accepting a tram-ticket from the conductor of the car. Indeed, a question on the subject was recently put to the Home Secretary. An ingenious French bacteriologist lately examined a number of these tickets and found them to contain germs innumerable and those of the deadliest character. Far be it from us to decry scientific research or bacteriological methods, but let us at least remember we live in a practical world. Desirable as the sterilisation of tram-tickets may be, it would be quite useless unless the conductor dealt them out with aseptic hands, and however aseptic the conductor's hands might be when he started out in the morning, they would certainly be freely infected by the first fare he received from a passenger. In a Utopian tram it might be possible for a conductor to wear a sterilised overall and to serve out sterilised tickets with sterilised hands, but in order to complete the requirements of hygiene he would have to deal only with sterilised passengers paying sterilised fares. At present the chief danger to be apprehended from the tram-ticket is the creation of hysteria in those who have yet to learn that the doctrine of the immanence of bacterium. With the 'bus-ticket there need be no difficulty as there is no obligation on the passenger to preserve it, and it may be thrown away as soon as it has been handed to him. The 'bus companies cannot demand that a ticket shall be produced for inspection, although they would fain have people believe they can. Let us, however, take our tram-tickets with thankfulness, asking no questions for conscience sake.

PERSONAL.

The following medical men had honours conferred upon them on the occasion of the official celebration of the King's Birthday last week:—

To be Knight Bachelors—
- Horace Rosborough Swanzy, Esq., M.D., President of the Royal College of Surgeons of Ireland.
- Mr. Alderman Thomas Boor Crosby, M.D., Sheriff of the City of London.

To be K.C.B. (Military Division)—
- Inspector-General Herbert Mackay Ellis, R.N., Honorary Physician to the King.

To be C.B. (Military Division)—
- Deputy Inspector-General Thomas Desmond Gimlette, R.N.
- Surgeon-General Francis Wollaston Trevor, Principal Medical Officer, Western Command, India.
- Colonel George Deane Bourke, Administrative Medical Officer, Southern Command.

To be Hon. C.I.E.—
- Dr. Jean Etienne Justin Schneider, Principal Doctor of the First Class, French Army, late Chief Physician to the Shah.

To be C.I.E.—
- Surgeon Lieut.-Colonel Warren Roland Crooke-Lawless, M.D., Coldstream Guards, Surgeon to His Excellency the Viceroy of India.

To receive the Kaisar-i-Hind Medal—
- Rai Bahadur A. Mitra, L.R.C.P. and S. Edin., Chief Medical Officer, Kashmir.

To be G.C.M.G.—
- Sir William MacGregor, M.D., K.C.M.G., C.B., Governor and Commander-in-Chief, Newfoundland.

The King has also specially appointed to the Order of the Bath the following veterans, who served in the Mutiny:—Surgeon-General Thomas Tarrant, Honorary Physician to the King; Deputy Surgeon-General Edward Malcolm Sinclair, late Army Medical Staff; Deputy Surgeon-General Alfred Eteson, late Indian Medical Service.

We have to congratulate Sir James Blyth, who has done so much to help forward the investigation of tuberculosis, on his being raised to the Peerage.

Dr. D. C. Watson was elected Assistant Physician, and Mr. W. J. Stewart, Assistant Surgeon, to the Edinburgh Royal Infirmary, on June 24th.

Dr. J. Odery Symes has been unanimously elected Physician to the Bristol General Hospital to fill the vacancy created by the death of Dr. Markham Skerritt. Dr. Carey P. Coombes has been elected Assistant Physician to the same institution.

Dr. R. H. Kennan, Senior Medical Officer of Sierra Leone, is acting as Principal Medical Officer of that Colony during the absence on leave of Dr. R. M. Forde, who has arrived in England.

Professor Osler will present the prizes to the successful students at the London School of Medicine for Women, at 4 p.m. to.morrow. The gathering will be held at the Royal Free Hospital, with Mrs. Garrett Anderson in the chair.

Mrs. Russell Sage has contributed £60,000 towards the foundation of an Institute of Pathology in connettion with the City Hospital and City Home on Blackwell's Island, New York. The main objects of the institution include the prosecution of researches into the diseases of old age.

Dr. J. J. Pursel has been elected Anæsthetist to Dr. Stevens' Hospital, Dublin, in room of Dr. J. L. Bell, resigned.

The honorary degree of M.D. was last week conferred by the University of Dublin on Dr. Conolly Norman and Dr. Philip Henry Pye-Smith.

A CLINICAL LECTURE

ON

SOME OF THE ORGANIC CONSEQUENCES OF HIGH BLOOD PRESSURE (a).

By LEONARD WILLIAMS, M.D., M.R.C.P.,

Physician to the French Hospital; Assistant Physician to the Metropolitan Hospital.

THESE five patients are here to illustrate some of the many morbid conditions which are associated with high blood pressure. In the minds of a great number of people high blood pressure suggests one morbid condition only, namely, granular disease of the kidneys. Such, however, is a very restricted view of the matter which, in the light which the manometer has afforded us, is no longer justifiable. Arterial hyper-tension is now very generally admitted to exist as a primary condition ; it is only when it has been in operation for a considerable length of time that organic changes supervene. Something, of course, must give rise to the hyper-tension itself, and this something in the majority of cases is the absorption of toxins from the gastro-intestinal canal. The stages through which the process passes, therefore, may be described as auto-intoxication ; high arterial tension, arterial degeneration. Arterial degeneration, as we know, is of two kinds : (1) that which affects the larger arteries and is called atheroma ; (2) that which affects the smaller arteries and arterioles and is called arterio-sclerosis. The burden of atheroma is borne by the aorta and the heart. In the former it provokes aneurysm, in the latter it gives rise to aortic valvular disease, and, by involvement of the coronaries, to angina pectoris and myocarditis. It is well, then, to remember that if we can recognise and arrest hyper-tension in its functional stage we may save our patient from these dread maladies. Arterio-sclerosis being a degeneration of the smaller vessels, it may of course appear in any tissue or organ, and when it is more marked in certain particular organs than it is in the system generally, a distinctive name is given to the condition, and we are in consequence apt to lose sight of the fact that hyper-tension may be at the bottom of the disease so designated. Thus it is that granular disease of the kidney and hepatic cirrhosis are often considered primary events, arterial hyper-tension being regarded as a result rather than as the cause of the disease. If we learn to look at the matter from the other point of view, and consider the sclerosis of the organ as a part of a general arterial sclerosis which has been induced by long continued high tension, the nature of these processes becomes very much more comprehensible. The functional stage of hyper-tension is one to which very much less importance is usually attached than its gravity merits. This is partly because its symptoms are very indefinite (breathlessness on slight effort being the only one which is at all prominent). and largely because its detection can only certainly be effected by the use of a manometer, an instrument the use of which is still unfortunately confined to the few.

The use of the manometer is certainly liable to be irksome, and as none of the reliable instruments are very portable, it may still be a long time before it vindicates its real value. In the meantime, in your endeavours to form an estimate of the state of the blood pressure without such assistance, I cannot insist too strongly upon the danger of trusting to mere palpation of the radial artery. Here, for example, is a man æt. 50, whose pulse, when felt, will be found to be perfectly compressible, whose radial artery seems to present nothing strikingly abnormal, who nevertheless has a very high blood pressure. The history of my association with him is interesting and instructive. He was admitted into the hospital with a profuse hæmoptysis, on the subsidence of which my house physician very properly examined his chest, and thought he detected some signs of tuberculosis. When I came to confirm this diagnosis, I found myself quite unable to do so. The lungs seemed to me to be quite free from any serious disease. The question then naturally arose : how was the undoubted hæmoptysis to be explained ? There was no phthisis, there was no mitral stenosis, the size of his heart was normal, there were neither casts nor albumen in his urine, and although he has a little emphysema, it did not seem to me to be a sufficient cause for the profuse hæmorrhage from which he had suffered. I therefore took his blood pressure with Dr. Oliver's new instrument, and found it registered 190 mm. Hg. This I regarded as a sufficient explanation of the hæmoptysis. My house physician wanted to know how high blood pressure in the systemic circulation could give rise to a hæmorrhage from the vessels in the pulmonic, the lesser, circulation. That is a very pertinent question, for it is obvious that the interposition of the capillaries, the veins and the valves of the right heart, render the pressure in the two systems absolutely independent of one another. It is of course true that if from any cause there is hyper-tension in the pulmonic circulation, there must inevitably be hyper-tension in the systemic circulation, because the pressure on the systemic side must always rise higher than the pressure on the pulmonary side. This is only another way of saying that arterial pressure must always be higher than venous pressure. As soon as this ceases to be the case the medulla is starved and the patient dies. It is also true that the same cause which produces hyper-tension in one system may produce it in the other, that is to say, the toxins acting on the interior of the vessels so as to bring about their contraction, may act as powerfully in the pulmonic circulation as they do in the systemic. This, however, though theoretically true, is uncommon, and need not therefore detain us. But the important point to remember is that hæmoptysis may, and very often does, occur even when the pressure in the pulmonary circulation is low. We are rather too apt to think of hæmoptysis in terms merely of the lesser, the pulmonary circulation ; we are rather too apt to forget, that is, that the lung substance itself is supplied with blood from the systemic system through the bronchial arteries, which are of course branches of the thoracic aorta, and that when there is hyper-tension in the systemic system, one of these arteries or their branches are liable to rupture. Such, I believe to have been the cause of the hæmoptysis in this man's case, high arterial tension with rupture of one of the branches of the bronchial arteries. The arteries in the lung, though better supported than those in the brain, are not as well supported as those in the ordinary systemic circulation. We do well, therefore, to remember that, after the brain the lung is perhaps the most frequent site for the rupture of a systemic artery.

(a) Delivered at the Medical Graduates' College and Polyclinic.

This next man shows a different stage of high blood pressure, for he has, I think, without doubt granular disease of the kidney. Unlike the first patient he has albuminuria and definite cardiac involvement. His heart's apex is outside the nipple line, and he has a reduplicated first sound, the sound which is very aptly described as a "bruit de galop." Now, these bruits, which are created by the interposition of an extra sound, are sometimes very difficult to distinguish the one from the other, but this sound, a true galop rhythm, which is as much apparent to the palpating hand as it is to the ear, is characteristic of definite cardio-vascular involvement. I do not ever remember to have heard it, in the form in which it is here present, except in a case of arterio-sclerosis or renal cirrhosis, which, as I have said before, are in reality but two different names for the same thing. A true "bruit de galop" consists of two short sounds and one long, and is best appreciated at the apex. The doubling of the second sound for which it ought not to be mistaken, though it sometimes is, consists of one long and two short, and is best heard at the base. This doubling of the second sound is due to asynchronous closure of two sets of basal valves, and is not in reality a "bruit de galop." The true "bruit de galop" is a pre-systolic sound, and is therefore very easily confused with the pre-systolic doubling of the first sound which occurs in early mitral stenosis. In early mitral stenosis the valves are thickened, and as the auricle contracts, the steam forces open the stiffened mitral segments, thus causing the extra sound. The French called it "*le claquement de l'ouverture de la mitrale.*" In arterio-sclerosis, the mechanism is somewhat similar. The auricle contracts and forces the stream of blood through the unimpaired valve, so that it impinges against the wall of the left ventricle, before the latter is fully dilated. The tardiness of the left ventricle in accomplishing its diastole is due to the fact that it is no longer purely muscular, that its substance has become invaded by fibrous tissue. This degenerative myocarditis represents the final stage of the process which beginning as functional high tension, leads progressively to arterial degeneration and cardiac involvement.

Inasmuch as these two conditions, chronic degenerative myocarditis and mitral stenosis, are both characterised by dyspnœa, that in both there may be hæmoptysis and œdema, and that in both the systemic blood pressure is liable to be very high, it is not surprising that in certain cases confusion may creep in. The importance, therefore, of ascertaining the real size of the heart by careful percussion cannot be over-estimated. In mitral stenosis the enlargement is to the right, in myocarditis the enlargement is to the left.

Where the mitral stenosis is accompanied by mitral regurgitation, the left ventricle may indeed be enlarged, but even so, the bulk of the enlargement will be on the right side, whereas in arterio-sclerosis the bulk of the enlargement is always on the left.

This next patient came to hospital complaining that though he could point to nothing which was definitely wrong with him, he had been feeling out of sorts for several weeks. When I came to examine him I found that he had a blood pressure of over 200 mm. Hg., and that his liver was enlarged, practically to the level of the umbilicus. His heart sounds are very difficult to hear, especially the systolic sound at the apex, but his aortic second sound is definitely accentuated. He has no murmurs or interpolated sounds, and his urine is free from albumen and casts. The case I believe to be one of hepatic cirrhosis of the alcoholic type, and I believe it to have been induced by high arterial tension whose long continuance unchecked has caused a sclerosis in the vessels of the liver. The subject of the causation of hepatic cirrhosis is not one which invites to dogmatism, but I submit that this view, which is very generally taught in France, serves to explain a good deal which on all other hypotheses must remain obscure. Moreover, cirrhosis of the liver of the alcoholic type is admittedly associated with general arterio-sclerosis and degenerative disease in the kidneys and heart. The hepatic manifestation may be regarded then as a part of a general toxæmia, the first physical sign of which has been a functional hyper-tension, leading insensibly to degenerative disease in the arterioles of the organ.

The two remaining patients are both women, and, characteristically enough, they display the results of their hyper-tension in the domain of the nervous system. This woman comes to us with the story of an attack of unconsciousness followed by a loss of power on the left side of the body—in point of fact a hemiplegia. There seems no reason to doubt the accuracy of her statements, because in out-patient practice we are familiar with numerous cases of a similar kind. These people have attacks of unconsciousness followed by paresis of one side of the body. They are admitted to the wards, and a short time afterwards they are discharged perfectly well. In the cases to which I refer, although the loss of power is quite definite, there are never any subsequent signs to indicate the existence of descending degeneration in the spinal cord. If you will examine this woman you will find that she has no ocular phenomenon, that her tongue is protruded mesially, that her grasps on both sides are equal, that her knee jerks are present, moderate in extent, and equal on the two sides, and, further, that she is free from ankle clonus, and that her plantar response is flexor. Now what is the explanation of these cases? The causes of hemiplegia are hæmorrhage, thrombosis, embolism and new growths. But it is obvious that any one of these, if sufficiently severe to give rise to an attack of unconsciousness must destroy a certain portion of the brain substance and give rise to permanent impairment of function. In this woman nothing of the kind has happened. We are justified therefore in assuming that whatever the cause of her hemiplegia, it was not one of the four classical causes which are generally recognised. There was in our grandfather's time a condition which used to be spoken of as "serous apoplexy" and I am strongly inclined to believe that the physicians of those days were right in their contention that such a condition can exist. If, for instance, we suppose a greatly increased fulness in the cerebral vessels, the inevitable result would be a filling of the ventricles and a pressure applied in all directions to the substance of the brain. Why that pressure should affect one side more than another, it is no more possible to explain than why it is that one artery should rupture in preference to another. When this woman came to see us, I thought I would test this view of the question by measuring her arterial tension, and I found that it was no less than 190 mm. Hg. Now if it stands at that figure generally, to what height must it rise in states of excitement or in such other conditions as we know to be capable of increasing the inter-vascular tension ? And if in such conditions it rises, as we may assume that it does, another 20 or 30 mm., it is not very difficult to believe that the pressure within the cranium may be such as to cause an effusion into the ventricles, and so press upon one of the internal capsules as to give rise to a passing hemiplegia. For we have to remember that the vessels in the brain are endowed with a power of contraction so slight that some competent observers still doubt its existence. A general rise of blood pressure would therefore certainly give rise to an overfulness of these arteries.

This last case is one of ordinary Bell's palsy, that is to say, a paralysis of the left side of the face unaccompanied by any condition which would lead us to suppose that the seventh nerve inside the cranium is organically affected. I need not remind you of the methods at our command for determining the exact seat of the lesion which may cause a facial paralysis of the peripheral type. The points are dwelt upon in the text-books and are beloved of examiners. The anatomical fact to which I want to direct your attention is well shown in this diagram of the cerebral arteries at the base of the brain in "Quain's Anatomy." There you will see that the anterior inferior cerebellar artery is given off by the basillar as soon as the latter has passed from the medulla to the pons. The branch as it passes outwards threads its way between the 6th, 7th, 8th, 9th, 10th, and 11th cranial nerves, and it is a remarkable fact that it passes over them all except the 7th and 8th, which two it passes under.

Now these cases of Bell's palsy are, as you know, described as "rheumatic" in origin, which is merely another way of saying that we have not the slightest idea as to their cause. "Rheumatic" to the ætiologist is an even more blessed word than ever Mesopotamia was to the theologian. I suggest that the anatomical distribution of this anterior inferior cerebellar artery may supply us with the explanation of this condition, whose cause has hitherto seemed so obscure. This woman, for example, has no rheumatic or "chilly" history, but she has a very high blood pressure. Her artery as it crosses these two nerves is therefore presumably distended. If, by emotion or "chill" or what not, this distension becomes augmented, it is not difficult to imagine that the vessel might exercise sufficient pressure upon the seventh and eighth nerves to give rise to serious, if temporary, embarrassment of function. In support of this explanation is the fact that this patient had a certain amount of deafness which accompanied the onset of her palsy ; the deafness and the palsy having disappeared coincidently. In further support of facial paralysis of the so-called "rheumatic" type having some causal relationship with high blood pressure is the fact that the only drug which hitherto has seemed to be of any service in the paralytic condition is iodide of potassium, and iodide of potassium, as we know, is a powerful reducer of blood pressure. The element of increased blood pressure in the causation of this affection is therefore one which seems to be deserving of more attention than it has hitherto received.

In endeavouring to come to a conclusion on the subject of the state of blood pressure when no instrument is available, I have already pointed out the futility of palpating the pulse at the wrist. A far more satisfactory method of arriving at a general conclusion is that of estimating what the French call the stability of the pulse. The pulse rate, we know, is normally 6–8 beats more rapid in the upright posture than it is in the recumbent. If this difference tends to become abolished then the probability is strong that the pressure in the arteries is unduly high ; and if it becomes reversed, so that the rate in the recumbent posture is greater than that in the upright, not only is it certain that the pressure is unduly high, but the probability is great that matters have progressed to the point of producing definite organic disease. This probability is rendered even more pronounced if, on examining the heart, we find the apex beat displaced to the left, a sign which by some authorities is considered as undoubted evidence that there is a sclerosis of the arteries in the splanchnic area.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by E. Percy Paton, M.S., F.R.C.S., Surgeon in Charge of Out-Patients to Westminster Hospital. Subject : "Some Observations on Intra-Abdominal Adhesions with Illustrative Cases."*

ORIGINAL PAPERS.

THE TREATMENT OF TYPHOID FEVER.

By E. STADELMANN, M.D.,

Hofrath Tit. Professor der Innere Medizin, and Director of the Städtl. Krankenhaus am Friedrichshain, Berlin.

The strivings after a specific form of treatment have, unfortunately, not led us much further. A serum, by means of which we could cut short typhoid, or modify or shorten its course, still remains undiscovered. The preliminary report of prophylactic inoculation appears to have given better results. Both in the Boer war in South Africa and in our own field-work in South-West Africa, typhoid fever has claimed its terrible sacrifices. The number of infections after preventive inoculation with deadened typhoid cultures carried out at home are said to have been considerably diminished. The breadth of bearing of this observation cannot be seen at a glance with any certainty, and at the present time no physician is in a position to be able to recommend preventive inoculation to those belonging to the families of those ill of the disease, somewhat in the same way as is done in the case of diphtheria, and often with good results. Wherefore the strivers of older dates who sought for an abortive treatment of typhoid fever have still many adherents. Liebermeister, to this end, recommended treatment by iodine—1 part iodine, 2 parts potassic iodide, 10 parts water, of which 3 to 4 drops were to be given every four hours in a glass of water, or potassic iodide alone in doses of 1 to 4 grm. daily. The calomel treatment had the same aim—2 to 3 doses of 0.2 to 0.3 grm. in the twenty-four hours for one day in the first or second week of the disease. It is quite conceivable that with the copious stools following the medicine, a good deal of infectious material was removed from the bowel, and that a certain amount of intestinal disinfection was obtained. I have often thought I had seen good results from this procedure in recent cases. But, on the other hand, I have never seen any from the administration of naphthalin, naphthol (40 grm. in one dose), or bismuth salicylate, which *should* also have a disinfecting action in the bowels.

Independent of the general management of typhoid patients (rest in bed, arrangement of the room, &c.) that is generally understood, the diet is of eminent importance. The food must be fluid, easily digested and absorbable. That many body substances, especially body albumen, are destroyed under the influence of the re-absorbed toxines, and of the fever, is undoubted, and it is impossible to prevent the consequences of this destruction by giving large quantities of albuminates and other feeding material. It must naturally be our endeavour to prevent the loss of bodily substance as much as possible, but this can only be effected by giving chiefly carbohydrates. The sickly organism does not bear flesh meat even in the mildest forms, and the patients object to taking it, and there are great difficulties in the way of giving fats, and even carbohydrates. In the first line in typhoid cases we must fall back on milk, which later on we may make more palatable to the frequently-objecting patient by the addition of coffee, cocoa, oatmeal. Milk soups, meat broths, soups of meal, rice, groats, even children's prepared foods, afford further changes, which we can make more nourishing by the addition of yolk of egg. The various artificially-prepared foods may also be tried, but more important and more nourishing is an egg in a glass of milk. Gelatine substances are an important nitrogenous food material which can be given to the patient as meat jelly, wine or fruit jelly. Fats are, at the most, to be given in the meals or groat gruel; cream, as whipped cream, with sugar, should be tried. Carbohydrates are best given in the form of sugar in the drinks, and a trial should be made of preparations of malt, In the feeding of typhoid cases it should be the rule to give something every two hours. In practice, however, when the patient is so often opposed to it, and there is as often a tendency to vomit, it is sometimes a very difficult thing to do. But you must not lose patience; you must still coax and try something new and novel.

A question as important as that of food is that of the drinks. The fever patient, with his raised temperature, requires a deal of water; he lies more or less in a semi-conscious state with half-open mouth, mouth, tongue, palate and fauces dried up, and a strong feeling of thirst is the outcome. We must not only satisfy this, but we must *make* the patient drink. Pure, fresh water is in the end the best taken by the patient, but there is no objection to the various lemonades. An excellent drink for quenching thirst is weak, sweetened, cold tea. A warning must be given as regards mineral waters that act as aperients or that distend stomach and intestines with carbonic acid gas. There is no objection to small doses of alcohol; large doses, such as were formerly given, are dangerous and even hurtful. The stimulating action of alcohol has not been proved, and our pharmacopœia offers us endlessly better and less harmful stimulants than that agent, and it possesses no antifebrile properties whatever.

THE ANTIPYRETIC METHODS OF TREATMENT.

I. Hydrotherapeutics.—In regard to fever, there are, as is known, two opposite views. The one, the older, sees in it a factor destructive to the organisms that must be combatted with the most powerful remedies; the newer view considers the fever as a protection to the organism against the toxic substances that have found their way into it. The truth here lies between the two; unusually high and long-continued high temperatures certainly result in serious mischief to the organism. But the fever alone does not dictate the treatment; the experienced physician does not judge of the severity of the disease from the height of the temperature alone; the patient's general condition is of far more importance to him. Experience teaches that cold baths, independent of the lowering of the temperature, act favourably in quite other directions. They make the sensorium freer, the pulse becomes stronger and less frequent, the morbid conditions of the respiratory tract improve, or they are arrested at the onset, food is better taken, the skin is properly cared for by the very treatment itself; decubitus, that occurred so frequently in former times, is avoided, the patients breathe more calmly and freely, the urine and stools are no longer voided involuntarily, &c. We have therefore arrived at quite different views as to the kind and manner of hydrotherapeutic treatment, as well as the indications for it. I have given up the former rule of ordinary baths at 16-12-10 (R), as soon as the temperature in the axilla has reached 39.5 (C), and content myself with cool or lukewarm baths at 30 to 32 (C). Here also one sees the temperature fall 1 to 1½ to 2 degrees, and the favourable influence on the general condition manifests itself. It is certain that in later time, even if the dangers of typhoid fever are unchanged, the temperature curves are undoubtedly considerably altered. The temperature curves, with a constant high temperature lasting two to three to four weeks, I have not seen for years. The fever has from the first a pronounced intermitting character, and maintains it through the whole duration of the fever. The baths are begun early, and continued until the fever ceases. Two or three a day are given generally during the height of the disease. If the temperature in the morning is normal one bath only is given, and that towards evening.

Of other hydratic forms of treatment to be mentioned are cold douching, which is not advisable, wet packings, which have only a slight effect, sponging of the body with cold water (not over 12 R.), with vinegar and water, 1 part to 4. The procedure is a mild one and may be used when baths, from any cause, are not allowable; the washing, if it is to be serviceable, must be repeated every two to three hours. The protracted warm baths introduced by Riess at a temperature of 25 to 27 R., in which the patient lies for hours, are used especially for very excitable patients as well as for alcoholics, and have a very soothing effect. The bed-bath, introduced by Krönig, may also be mentioned, of which I have no experience.

Bath treatment must be unconditionally forbidden in cases of intestinal hæmorrhage, peritonitic irritation, as well as in peritonitis. One must be very cautious in cases of cardiac weakness, cardiac diseases, arterio-sclerosis, old heart failure, tuberculosis, bronchiectasis, that is, diseases with a tendency to hæmorrhage from the lung tissues, in emphysema of the lungs, in old fatty people, in chlorosis, anæmia, and alcoholics. Priessnitz packings, when baths are not available, are quite suitable.

II. Antipyretic Medicines.—A large series of febrifuges have been used, quinine, antipyrine, phenacetin, antifebrin, lactophenine, pyramidon.

These I practically never give, as I have become convinced that no real advantage can be gained by them. Antipyrin has very unpleasant bye-effects as regards the stomach; phenacetin and antifebrin are poisonous drugs best altogether eliminated from the physician's armamentarium. In regard to lactophenine, which in doses of from 4 to 6 grm. daily brings about a prompt reduction of fever, I have no experience. Pyramidon is said to act in a similar way, but I cannot join in its praise. Often, in doses of 0.25 to 0.30, given five times a day, it has failed to reduce the temperature for any length of time. Vomiting often took place after it; loss of appetite, and profuse sweating distressed the patient very much. The salts of pyramidon do no better. Quinine acts best given in one dose of 1 grm. to 1½ grm. before the height of the fever. But even this drug has so many disadvantages (singing in the ears, a species of intoxication, deafness and feeling of unwellness, tremors, and even collapse), that I now scarcely ever use it in typhoid; it cannot be compared to the treatment by baths.

The Treatment of the Disturbances on the Part of the Various Organs.

The disturbances of the central nervous system (somnolence, apathy, restlessness, delirium, sleeplessness, &c.) are influenced in the most favourable manner by the baths. With them an ice-bag may be applied to the head. In case of great restlessness and insomnia a morphia injection of 0.01 to 0.015 grm. may be given with a favourable effect on the general condition also. On the side of the circulatory apparatus the dangers of threatening cardiac weakness are very great. In such cases of collapse I have never seen any real good from alcohol. It is much more important to make use of the excellent excitants we have in our pharmacopœia. Digitalis does not act favourably, and is very often badly borne. On the other hand, early subcutaneous injections of Ol. camphoratum and natrosalicylate of caffeine (in heroic doses 1 to 2 syringefuls of a solution of 2 : 10 every two hours); æther is uncertain in its action, and extraordinarily painful. The intestinal tract demands special careful supervision and therapeutic treatment. Moderate diarrhœa requires no medicinal treatment; on the other hand, if it is profuse I prefer giving ten drops of tinct. opii. in a mucilage or starch enema. Excessive meteorism is very favourably influenced by bismuth subnitrate or subsalicylate, the application of an ice-bag, or the insertion of a rectal tube. If the bowels are blocked, no aperient must be given, but a mild enema or injection of oil.

In hæmorrhage from the bowels, even if of the slightest, absolute rest, limitation of diet and drinks, and the baths must be stopped. If the hæmorrhage is severe, only pills of ice should be given for the thirst. Medicinally, acetate of lead, 0.05 to 0.1, every hour or two, dialyzed ext. ergotæ 2 : 10, a syringeful every half hour or every hour, stypticine 0.03 to 0.1 several times a day by subcutaneous injection, gelatine (pure) injected in a 2 to 5 per cent. solution, at first 4 grm. at once, then twice more in a dose of 2 grm. at intervals of a day or two. An absolutely reliable (sterilized) preparation is made by Merck, of Darmstadt, the solution being already prepared and put up in sealed vessels. Adrenalin, 10 drops of a 1 : 1,000 solution, every two hours for a day or two days. I have never been able to convince myself with certainty of the beneficial action of the two remedies last named. In case of violent and repeated epistaxis, careful tamponnade of the nostril affected from behind.

When perforation of the bowel takes place the prognosis is almost hopeless. Absolute rest, prohibition of all foods, and even fluids. Whether any real good is obtained by operative measures I do not know. In addition to rest and cold applications, opium and morphine should be given to keep the bowels quiet, and to favour the formation of adhesions and the relief of pain.

For the prevention of extensive catarrh of the lungs and pneumonia, cold water treatment is the most suitable. Decubitus must be avoided with the most painful care; typhoid patients must be placed from the first on a water-cushion, and in furtherance of avoidance of the mischief, bath treatment is still the best on account of the cleanliness and care for the skin associated with it. On the first sign of its appearance the part must be rubbed with spirit of camphor, boric lanolin, or boric vaseline. If decubitus has already appeared, a dressing of antiseptic remedies must be ordered, amongst which a 1 in 30 dressing of balsam of Peru is suitable. Great care must be taken regarding the onset of an attack of nephritis, in consequence of toxic material either taken into the system or arising from the typhoid bacilli themselves. If the bladder becomes paralysed the catheter must be made use of.

Relapse and recurrence are to be looked upon as very dangerous; their treatment does differ from that of the original fever, but on account of the organism being already weakened by the preceding illness, the greatest caution is necessary, especially as regards treatment by baths.

After convalescence has set in, the fluid diet must still be continued for a week; not till then may the patient take more solid food in the shape of soaked and softened biscuit (Zwiebach) or English biscuit, gruel, &c. Flesh meat must not be given for ten or fourteen days, and then either scraped or minced. After the third week the ordinary diet may be given. Exceedingly strict warning must be given against any errors in diet; even if they cannot cause a relapse they can, at any rate, favour the onset of one, as the virulent bacilli still present in the intestines may, after any error of diet, possibly set up a new disease.

In milder cases, if the patient is not too much run down, he may attempt to get up after the fever has been away for a fortnight; but in severe cases not until after three or four weeks. The time for being out of bed may gradually be lengthened, and if the weather is fine the patient may go out after the fourth week. The usual vocation should not be returned to until after another six or eight weeks' recuperation. The consequence of returning to work too early and before the powers have become restored is a long lingering feeling of lassitude, inability to work properly, and general feeling of not being well.

A NOTE ON RHINORRHŒA IN FAUCIAL DIPHTHERIA.

By J. D. ROLLESTON, M.D., B.Ch., Oxon.

Assistant Medical Officer, Grove Hospital.

From an early stage in the history of diphtheria the occurrence of nasal discharge preceding or accompanying the angina has been well known. Misled by the fact that a nasal discharge, apparently benign in nature, may sometimes precede very severe diphtheria, Bretonneau, who first established diphtheria as a specific disease, formulated the law that diphtheria always has a nasal origin. The nasal fossæ according to him were the nest from which the membrane is carried to the lower parts. The exaggeration of this statement was obvious. Trousseau, between whom and Bretonneau a controversy arose, had no difficulty in showing that diphtheria is not always preceded by a nasal discharge, and fell into the opposite error of denying the possibility of the nasal onset of diphtheria. Membranous coryza, according to Trousseau, was merely a complication of the angina. The question of the nasal origin of diphtheria was soon forgotten, and it is only within the last few years that it has been revived by Sevestre, who states that careful inquiry from the parents of children affected with faucial diphtheria will often elicit a history of a nasal discharge. More recently Marfan has declared that while it is rare for a child to complain of a sore throat at the very beginning of diphtheria a mucous hypersecretion of the nostrils at that time is not uncommon. The pharyngeal tonsil, according to Marfan, is probably the site of origin of diphtheria. It is obvious that pre-existing adenoids would predispose to diphtheria originating in such a spot. The frequency of adenoids in fatal cases of diphtheria has been shown by Cottier, who in 38 autopsies on diphtheria patients found adenoids in 50 per cent.

The great authority of Trousseau is responsible for the erroneous doctrine that a nasal discharge in diphtheria is invariably of bad omen. "Coryza, even of a slight degree, is a serious occurrence, for it indicates that the specific phlegmasia has invaded the nasal fossæ. . . . Of 20 individuals affected with nasal diphtheria 19 succumb, while of 20 affected with croup you can save a certain number by tracheotomy." Two subsequent writers of the pre-antitoxin era, Cadet de Gassicourt and Henoch, showed that Trousseau's statements were too absolute, both asserting that a nasal discharge during the acute stage of diphtheria was compatible with a mild attack. The truth of this view is confirmed by my own experience, as will be seen below.

The present paper is based on 1,200 consecutive cases of diphtheria that have been under my care in the course of the last four years. Of these, 323, or 26.91 per cent., on admission to hospital, or subsequently during the acute stage, presented a discharge from the nose. There was also a history of recent nasal discharge since the commencement of the disease in 177 others (14.75 per cent.), though in them no nasal discharge was observed either on admission or subsequently. Thus a total of 500, or 41.6 per cent. of all the cases had some nasal involvement. (*a*) These figures are probably too low, for a slight degree of nasal discharge before admission to hospital may have escaped the notice of the patient or his friends. Further, it must be borne in mind that the absence of rhinorrhœa, or of visible membrane in the nostrils, does not necessarily imply that no nasal diphtheria exists. The nasal membrane may, as autopsies show, be limited to the posterior part of the nares, from which the discharge passes down into the pharynx instead of externally.

As only four of the 177 cases with nasal discharge prior to admission had received antitoxin before admission, and two of the four on the same day that they were admitted, it is obvious that nasal discharge may cease spontaneously. This is most likely to occur in cases which run a mild course, as is shown by the following tables, from which it is seen that, while the self-limiting nasal discharge becomes progressively more frequent in the milder cases, the more persistent nasal discharge becomes progressively more frequent in the severer cases.

Table I.—Cases in which nasal discharge occurred as a prodromal symptom, but was not present on admission to hospital or subsequently.

Character of Faucial Attack.	Total Number of Faucial Cases	Cases with Prodromal Nasal Discharge.	Percentage.
Very severe	121	9	7·43
Severe	225	24	10·6
Moderately severe	108	12	11.1
Moderate	305	53	17·37
Mild	428	79	18·45
	1,187(*b*)	177	

Table II.—Cases in which nasal discharge was present on admission, or developed subsequently during the acute stage.

Character of Faucial Attack.	Total Number of Faucial Cases.	Number of Cases with Nasal Discharge.	Percentage.
Very severe	121	89	73·55
Severe	225	112	49·77
Moderately severe	108	30	27·7
Moderate	305	48	15·73
Mild	428	44	10·28
	1,187	323	

Further evidence of the greater severity of the cases in which the nasal discharge persisted until admission is afforded by the following figures. Out of 92 deaths in the 1,200 cases 16, or 1·8 per cent., occurred in the purely faucial cases, among which are included those which had a history of nasal discharge prior to admission only; 14 or 11.1 per cent. occurred in the faucial and laryngeal cases; while in the faucial and nasal cases there were 59 deaths, or a mortality of 18·2 per cent. Intercurrent diseases were responsible for 3 deaths, two being due to scarlet fever, and one to congenital syphilis.

The incidence of albuminuria and paralysis, the frequency and severity of which bear a direct relation to the character of the initial attack, was greatest in the nasal cases. Thus, among the purely faucial cases there were 135 paralysis cases (15·6 per cent.), 27 of which were severe, while in the faucial and nasal cases there were 143 paralysis cases (44·2 per cent.), 59 of which were severe. So with albuminuria. In the faucial and nasal cases there were 215 albuminuric cases (66·5 per cent.), in 32 of which the albumin persisted for three weeks or more; in the purely faucial cases there were 395 albuminuric cases (45·8 per cent.), in 19 of which the albumin was present for more than three weeks.

In the cases of self-limiting nasal discharge the rhinorrhœa was a very early symptom starting as a rule at an earlier date than the nasal discharge which persisted until admission.

This is shown by the following tables :—

Table III.—Day of disease on which a nasal discharge was first noted in cases which on admission and subsequently had none.

(*a*) Seven purely laryngeal cases and six purely nasal cases which have not been included complete the 1,200 cases.

(*b*) Very similar figures are quoted by Glatard, who says that out of 177 cases of diphtheria admitted to the Hôpital Bretonneau, 42.9 per cent. contained diphtheria bacilli in the nose. The great majority of those cases showed clinical evidence of nasal diphtheria as well. It pre-antitoxin times Garnier (quoted by Glatard) found nasal diphtheria in 41·05 per cent., or in 39 out of 95 cases.

1st day	88 cases
2nd „	43 „
3rd „	28 „
4th „	6 „
5th „	7 „
6th „	5 „
	177 cases

Table IV.—Day of disease on which a nasal discharge was first noted in cases in which it was present on admission or subsequently.

1st day	89 cases
2nd „	69 „
3rd „	68 „
4th „	50 „
5th „	37 „
6th „	6 „
7th „	4 „
	323 cases

Though the self-limiting nasal discharge was more common in young children it was not confined to them; 26 out of the 177 cases occurred in patients between the ages of 10 and 36 years.

A previous history of recent nasal discharge was more frequent in the laryngeal cases than in those which were purely faucial. Out of 133 laryngeal cases in the 1,200, 31, or 23.3 per cent., had such a history; while out of 861 purely faucial cases, 152, or 17.65 per cent., had had a nasal discharge at the beginning of their illness. It is interesting to note that in three out of seven cases (42.8 per cent.), which on admission were clinically cases of purely laryngeal diphtheria, there was a recent history of nasal discharge. Such cases are especially likely to occur in very young children. The nasal diphtheria of infants usually remains localised to the nose, but it may spread, the membrane passing down the sides of the pharynx, where it may easily escape observation. In seven cases of nasal diphtheria in nurslings recorded by Ballin there were two in which the larynx was affected.

Summary.

1. A large percentage of all cases of faucial diphtheria admitted to hospital has a history of rhinorrhœa.
2. In a certain number of cases which clinically are purely faucial, rhinorrhœa is an early symptom, subsequently disappearing without treatment.
3. The frequency of this early and transitory rhinorrhœa bears a direct relation to the mildness and an inverse relation to the severity of the faucial attack.
4. Faucial cases which are also clinically nasal are more severe than those which are clinically faucial only.
5. Faucial cases which are also clinically nasal as a rule develop the nasal discharge at a later date than those which are clinically faucial only.
6. Early and transitory rhinorrhœa is relatively more common in laryngeal cases than in those that are purely faucial.

URÆMIA (*a*).

By ALFRED E. RUSSELL, M.D.Lond., M.R.C.P.,

Assistant Physician West London Hospital.

The purpose of this paper is to put forward the proposition that there is evidence to show that the cerebral manifestations of uræmia are dependent upon cerebral anæmia, produced by an increase in intracranial tension resulting from cerebral œdema. In other words, the old and abandoned hypothesis of Traube will be reconsidered in the light of recent experimental and clinical work on conditions of increased intracranial tension with their associated alterations of blood pressure.

(1) The Physiological Results following Increased Intracranial Tension.

This question has been studied experimentally by Harvey Cushing (*b*). He increased intracranial tension in dogs by trephining and applying pressure to the surface of the brain by means of a distensible rubber bag, communicating with a burette containing mercury. He showed that if the intracranial pressure be rapidly increased, "Kussmaul Tenner spasms, evacuation of bladder and rectum, practical cessation of respiration, and pronounced vagus effect upon the heart, often with a complete standstill, lasting from ten to twenty seconds, may develop. Then follows a release from this extreme vagus inhibition and the vasomotor centre exerts its influence." With a slower increase of the intracranial pressure a different series of events occurred. The pressure against the brain could be increased to the point of its equalling the blood pressure before any symptoms referable to the centres in the medulla were called forth. Direct examination of the cortex through a circular disc of glass fitting tightly into a second trephine hole showed, at this period of equalisation of blood pressure and intracranial tension, an *abrupt blanching* of the exposed convolutions. The pulsating arteries could be seen against the blanched background and the dark blue veins in the sulci remained filled with blood, but presumably little, if any, circulation passed between them. The usual consequence was not death but *a stimulation of the vasomotor centre, which occasioned a rise in blood pressure sufficient to overcome the high intracranial tension*; the cerebral circulation was re-established and the rosy colour could be seen through the glass window in the trephine hole to return again to the blanched convolution. With further increase in intracranial tension the blood pressure rose *pari passu*, and always to a point exceeding the intracranial tension. This process could be repeated until the arterial pressure was forced to two or three times its normal level, sometimes to as much as 250 mm. Hg., without evidence of vasomotor failure.

If by division of both vagi their influence on blood pressure and pulse rate were cut out, the blood pressure followed the increase of intracranial tension even more closely. If the spinal cord were divided in the cervical region, and thus the vasomotor control of the great splanchnic area lost, then increase in the intracranial tension produced only a vagus slowing of the pulse with no rise of blood pressure; while if both cord and vagi were divided no alteration whatever in either pulse or blood pressure occurred on increasing the intracranial tension. In face of these experiments Cushing's conclusion that an increase of intracranial tension occasions a rise of blood pressure which tends to find a level slightly above that of the pressure exerted against the medulla seems absolutely justified. By this mechanism the vital centres in the medulla and the life of the brain and entire animal are protected.

(*a*) Read at a meeting of the West London Medico-Chirurgical Society, December 7th, 1906.

(*b*) "The Regulatory Mechanism of the Vasomotor Centre which Controls Blood Pressure during Cerebral Compression."—*Johns Hopkins Bulletin*, Sept. 1901. For fuller account see also Cushing's Mütter Lecture for 1901, in the *American Journ. of the Med. Sciences*, Sept., 1902.

(2) Certain Clinical Conditions Associated with an Increase of Intracranial Tension.

It is well established that many of the symptoms of cerebral tumour, hydrocephalus, cerebral hæmorrhage, &c., are dependent upon an increase of the intracranial tension. Among such symptoms may be mentioned headache, vomiting, coma, convulsions, choked disc, &c. Extraordinary relief to these symptoms is attained after the pressure is relieved by surgical intervention. An admirable series of cases has been recorded by Harvey Cushing (*a*). In another paper Cushing (*b*) gives the records of five cases of intracranial hæmorrhage, four traumatic and one apoplectic. These illustrate from the clinical standpoint the facts ascertained by him experimentally. As the case of apoplectic hæmorrhage is of great importance I give it in detail.

Resumé.—Apoplexy with right hemiplegia, symptoms of pronounced intracranial tension evidenced by a blood pressure ranging about 300 mm. Hg.; threatened symptoms of medullary paralysis, major symptoms (bulbar) immediately relieved by craniotomy and aspiration of intracerebral clot, subsequent replacement of flap, death on the third day from pulmonary complications.

Man, æt. 40, admitted to hospital thirty-six hours after onset of symptoms. He was in a state of profound stupor with right-sided flaccid paralysis. Temperature 99.6°; respiration varied from 21 to 27; pulse 50 and of high tension, registering 300 mm. Hg. Conjugate deviation of eyes to right with nystagmus. Pupils equally contracted and reacted to light. Veins of forehead were greatly distended.

Operation.—A large osteoplastic flap was turned down over the left hemisphere. The dura was tense and without pulsation. On incising it the brain bulged far into the opening and began to pulsate actively. The convolutions were greatly flattened, deeply cyanosed, and the veins occupying the sulci were widely dilated, and their contents so dark that the colour contrast between veins and arteries was of an unusual degree. Blood was evacuated from the hemisphere by means of a grooved director, about two teaspoonfuls. The blood pressure began at once to fall and in twenty minutes had reached the normal level. The pulse rate during this fall in blood pressure remained unaltered. The release from intracranial tension was evidenced by the immediate collapse of the bulging hemisphere. On the following day the patient's condition had greatly improved. The pulse rate and blood pressure remained normal, respiration was no longer laboured, stupor was much less deep, and he could be roused with considerable ease. The conjugate deviation disappeared and he seemed to see and recognise objects. Stupor returned on the following day, though the blood pressure only rose to about 160 mm. Hg.; œdema of lungs set in, and he died two days later. *Post mortem*, a large hæmorrhage was found in the white centre of the left hemisphere.

The clinical evidence as obtained, therefore, from cases of cerebral tumour, cerebral hæmorrhage, &c., is in complete accord with the conclusions derived from a study of Harvey Cushing's experiments. To recapitulate—it is clear that a rise in intracranial tension by the introduction of any foreign element such as a tumour mass, blood, &c., must tend to diminish the blood flow through the brain. If the tension increases, a point would be reached at which the intracranial tension equals that of the general blood pressure. The cerebral circulation would therefore cease were it not that by a compensatory process the general blood pressure rises to a point above that of the intracranial pressure, and thereby maintains the flow of blood through the brain.

But with a great increase of intracranial tension, certain general effects are produced apart from focal symptoms dependent upon the position of the lesion. Headache, for instance, is common, and is probably attributable to tension of dura mater and tentorial structures. It is probable that the brain tissue itself is insensitive, and the fact that Cushing notes that after excision of the Gasserian ganglion for severe trigeminal neuralgia, any subsequent headache is only felt on the side with the intact fifth nerve, points in the direction that intracranial pain is experienced *via* the fifth nerve.

Optic neuritis is to be attributed, in the main, to a passive venous congestion of the retinal veins, and subsides or improves on relief of intracranial tension, sometimes with extraordinary rapidity.

Finally, coma is almost invariable in the last stages of cerebral tumour and in large cerebral hæmorrhages. Convulsions are also frequent in these conditions. Both are remarkably improved by methods capable of lowering the cerebral pressure, such as trephining or lumbar puncture. And it is to be noted that, by lowering the intracranial tension, a free access of blood to the brain is facilitated.

(3) Uræmia.

In cerebral uræmia we frequently see a symptom complex almost identical with that of cerebral compression, viz., headache, vomiting, drowsiness, coma, convulsions, optic neuritis, &c. This symptom complex is, at any rate in great measure, dependent upon increased intracranial tension, for many cases are now on record in which extraordinary relief has followed lumbar puncture, a procedure which, by means of allowing some of the fluid to escape, diminishes the pressure within the cerebro-spinal space.

Thus MM. Pierre Marie and Georges Guillain (*a*) record the case of a man, æt. 20, suffering from nephritis and epilepsy, who had suffered from severe headache for twelve months, with a high blood pressure (200 to 210 mm. Hg.). Lumbar puncture was performed, the cerebro-spinal fluid being under greatly increased tension, as it spurted out from the needle; 6 cc. were withdrawn. Within five minutes the headache was materially improved, and within two hours it had completely disappeared. Relief was complete for two days, when the communication was read. In the discussion which followed the paper, M. le Gendre recorded a similar case of relief. A man, æt. 57, painter, suffering from arterio-sclerosis and plumbism with albuminuria. He was uræmic with headache, myosis and insomnia. Lumbar puncture was performed, and 13 cc. withdrawn. The pressure was not noted. The same evening the headache was improving, and he slept well. The headache progressively improved, and in three days was absolutely gone.

In a further communication M. Pierre Marie pointed out that lumbar puncture for uræmia had been performed for the past six years in Germany, and he quoted three cases of cure of headache in saturnine encephalopathy, by Seegelken, Brash and Nölke. Marie, however, was careful to point out that other observers had not found lumbar puncture of help in the treatment of uræmia, and instanced as examples Quincke, Furbringer, Lichtheim, von Leyden, Stadelmann, Braun and Lenhartz. But he remarks that most of the above negative records were not accompanied by details of the circumstances under which the puncture was performed. G. Scherb (*b*) records a case of nephritis with uræmia in a man, æt. 49, suffering from very severe headache, and resisting all treatment. He was admitted to hospital almost comatose, with history of vomiting, auditory hallucinations and severe insomnia. Fundi showed slight venous stasis. Increased arterial tension. Incontinence of fæces. Lumbar puncture was performed, and 20 c.cm. removed, the fluid issuing in a spurt under considerable pressure. Within five hours he was conscious and could answer questions. Next day he was quite free from headache and remained so for six weeks, when

it returned. Œdema also appeared, limited to the region of the forehead, eyelids, cheeks, lips, ears, and the skin of the scalp. Lumbar puncture was again performed, but with only temporary relief, and death occurred tens days later.

D. C. McVail records two very successful cases (*a*). In the first case a man with acute nephritis, with severe intracranial pain, followed by convulsive attacks repeated during thirty-six hours, became almost blind, and finally comatose. He was œdematous. Lumbar puncture was performed, the fluid issuing in drops, and apparently under no tension. Within twenty-four hours there was a return of consciousness and sight began to reappear. He slept well, and on the next day was free from pain, with perfect vision. This was followed by a rapid recovery from the renal condition. The second case was also one of acute nephritis, with moderate œdema. Within thirty-six hours of admission to hospital, and in spite of all treatment, he lapsed into deep coma. One ounce of fluid was withdrawn by lumbar puncture, again issuing in drops. Consciousness returned in four hours; he slept well, and next morning was quite rational. He also left the hospital free from albumen. McVail attributes the symptoms in these cases to increased intracranial pressure.

T. Arthur Helme (*b*), F. Proud (*c*) and R. N. Willson (*d*) record instructive cases of puerperal and uræmic convulsions in which relief was immediately obtained by lumbar puncture.

F. C. Eve (*e*) notes the case of a man with uræmic convulsions associated with total blindness. The convulsions were relieved by venesection, but the coma remained. Lumbar puncture was performed (fluid under high pressure). Next morning the man was quite conscious, and had recovered much of his sight.

Remarks.—The above cases are sufficient to show that marked relief may follow lumbar puncture in cases of uræmia. It is well known that uræmic convulsions and coma may disappear apart from such treatment, but the promptitude with which the improvement occurred was such as to leave no doubt in the minds of the observers that the relation was one of cause and effect. It is noteworthy also that in most of the cases the cerebro-spinal fluid did escape under considerable pressure. McVail states that in neither of his cases was there any increase, the fluid merely dropping away. Nevertheless, his two cases were strikingly successful, and he attributed the relief to the puncture, which obviously acts by diminishing the pressure of the cerebro-spinal fluid. It would be expected that the fluid would always issue from the needle with force, as, indeed, the above records show that it often does. But there are several points to consider. The needle is necessarily a fine one, and if its lumen became partially blocked in its passage through the tissues of the back, the fluid could only find its way out in drops. Another point is that there is at present no reliable instrument for measuring the tension of the spinal fluid. Eve's instrument, though very useful, only measures the height of fluid which finds its way out of the spinal space into a vertical glass tube connected with the needle. But this height of fluid is not a measure of the real pressure of the fluid in the cerebro-spinal space, for we have to consider that space as a practically closed-in cavity with walls of considerable rigidity. This cavity is always full of fluid or semi-fluid substance, and to force more fluid into such a space would necessitate great pressure, its normal contents being very little, if at all, compressible. Doubtless the ligaments of the spinal column would yield slightly, but scarcely to any great extent. It is therefore obvious that the addition of but a little fluid would very materially raise the pressure, and that this pressure would not be measured by the small amount of fluid which escaped into a vertical tube in connection with a needle in the space. To measure it, it would be necessary to puncture the space with a needle full of fluid and attached to a mercury manometer, the whole of the connecting tube as far as the mercury in the first limb being filled with fluid. Then, on inserting the needle into the space, the mercury in the proximal limb of the manometer would be depressed. The actual pressure would be ascertained by pouring mercury into the distal limb until the mercury meniscus in the proximate limb returned to the same position it occupied before the puncture was made. The difference in level between the two mercury menisci would be the measure of the real intraspinal pressure. Hürthle's manometer might also be used for the purpose, as the movement of fluid in and out of the tambour is exceedingly small. Another difficulty is that the cerebral pressure is relieved by removal of the *free* cerebro-spinal fluid. If, however, the pressure is mainly produced by a cerebral œdema, then unless a co-existent excess of free ventricular fluid was present, the removal of the little that would flow might not be sufficient to relieve the pressure materially. This fact might explain some of the cases in which relief is not obtained.

The manifestations of uræmia here considered which are so strikingly relieved by lumbar puncture are, as has been pointed out, so closely similar to the pressure symptoms produced in other conditions, such as cerebral tumour, cerebral hæmorrhage, &c., that uræmia has not infrequently been erroneously diagnosed as cerebral tumour, and the fact that the cerebro-spinal fluid is often under considerable pressure in these cases of uræmia, indicates that the underlying condition of increased intracranial tension must be responsible for the symptoms. Harvey Cushing also suggests this.

Uræmic Coma.—It has been pointed out that cerebral compression would produce a cerebral anæmia were it not that the blood pressure rises so as to keep just above the cerebral pressure and so maintains the cerebral circulation. But this compensatory process cannot go on indefinitely, and a certain point may be reached beyond which no amount of vasoconstriction and cardiac augmentation can maintain an adequate cerebral circulation. If this point is reached gradually and the volume of blood passing through the brain be slowly diminished, we should expect a comatose condition to develop, the last stage of cerebral compression with gradual respiratory failure; the high tension slow pulse of the early stage of compression changing into a soft, rapid pulse with the developing vasomotor failure. A concomitant toxic action on the brain is not denied; such may be present and aid in the production of the cerebral symptoms. But the anæmia alone should suffice to induce the coma.

Uræmic Convulsions.—Under the severe strain imposed upon it in working against a very high blood pressure the heart may fail rapidly in chronic nephritis. Should this occur, or should the vasomotor centre fail rapidly, it is clear that the cerebral circulation must fail equally rapidly when the intracranial tension is pathologically high. Instead of headache and somnolence, gradually deepening into coma, a more sudden unconsciousness would result, and if the failure in the circulation through the brain occur almost suddenly, convulsions would readily be produced. It is well known that sudden cerebral anæmia is a most potent cause of convulsions, as, for instance, in the well-known experiments of Kussmaul and Tenner, also after severe hæmorrhage, &c. The author has reported cases (*a*) in which the pulse stopped before the onset of ordinary epileptic fits, and has suggested that the cerebral anæmia so produced is sufficient in itself to account for the ordinary epileptic fit. It is of great interest to note that the onset of uræmic convulsions is, in fact, very apt

to be associated with marked evidences of circulatory failure.

According to Senator (*b*), "before the convulsions the pulse is often tense and slow, but during the attack it is small and accelerated and often irregular; as a rule, however, it cannot be counted accurately until after the attack, when it is also retarded in most cases." According to Strumpell (*c*), "the pulse is often very slow before the appearance of severe symptoms, sometimes 48 or 40, but it is almost always tense and hard. In chronic uræmia also a moderate slowness of the pulse is not infrequent. *When uræmic convulsions appear, however, the pulse usually becomes small and very frequent, especially in cases that terminate unfavourably.*" Willson's cases are of the greatest importance in this connection, especially as in his six cases of uræmic convulsions the convulsions terminated in every case on the withdrawal of the cerebro-spinal fluid; and it is to be noted that his best results were obtained in those cases in which the fluid spurted from the cannula, *i.e.*, in which the pressure within the cerebro-spinal space was greatest. *And this withdrawal of fluid by lowering the cerebral pressure would allow of an immediate return of blood to the brain.*

In cases of acute uræmia in acute nephritis it is well-known that an increase of blood pressure is common, and the cardiac failure may be more readily effected owing to the more toxic character of some of the diseases associated with acute nephritis, the poisons of the acute infections, such as scarlet fever, materially affecting the heart muscle. The heart would thereby be unable to respond to the vaso-constriction above described and the conservative rise of blood pressure would fail to develop.

This paper revives the old and discredited hypothesis of Traube, who considered that the cerebral anæmia was brought about through a compression of the blood vessels by œdema fluid. For this theory to rest on a sound basis it would have to be demonstrated that œdema does occur.

As regards this point, it is commonly stated that cerebral œdema is present or may be present in people dying of uræmia. Thus Senator, who though on the whole an opponent of the œdema theory, states (*d*), "It is quite true that œdema of the brain is frequently found in the bodies of those who have died of uræmia," but he adds that "the mere fact that this œdema of the brain is not constantly found proves that at most it is the cause in only part of the cases, providing, as Bartels believed, the œdema is not the result of the convulsions." The writer (Senator) does not think, however, that Bartel's view is correct; "for œdema of the brain is not always found even after the most violent convulsions produced by a great variety of poisons. But the fact that œdema of the brain is a frequent occurrence in uræmia does not in itself justify the conclusion that the two conditions have a casual connection, although it lends a certain modicum of probability to such a view. . . . It may be admitted that œdema of the brain in many cases is partly responsible for the development of uræmia, although other factors are probably present also. The writer is very much inclined to regard a circumscribed œdema of the brain as the cause of many focal manifestations, particularly amaurosis and hemiplegia, for which it would be difficult to find another explanation. . . . The irritability of the nervous centres is of the first importance, especially for the onset of a typical acute uræmic attack. . . . The immediate effect of the irritability appears to be a contraction of the small arteries, causing acute anæmia of the brain, which is a possible factor in the production of the attack, although it is probably not followed by cerebral œdema, as Traube asserts."

Senator, therefore, associates the attack with a cerebral anæmia whether produced by œdema or arterial spasm, but inasmuch as in many cases at least the intracranial tension is increased as shown by the spurting out of cerebro-spinal fluid on lumbar puncture, and by the extraordinary relief thereby effected, it is very probable that cerebral œdema with excess of cerebro-spinal fluid is commonly present in these cases. Such œdema would of necessity hinder the free access of blood to the brain, and the cerebral anæmia thereby produced would, in the absence of a compensating rise of the general blood pressure or on the failure of this compensating rise, account for many of the symptoms.

If this hypothesis be correct and if uræmic convulsions be due to a sudden cerebral anæmia as above suggested, considerable support is lent to the theory that epilepsy is produced by a sudden cerebral anæmia, for it is notorious that the convulsions of uræmia and of idiopathic epilepsy may be absolutely indistinguishable, and it is extremely probable that the factor underlying conditions so remarkable and so identical should be one and the same. The practical application that follows from the above is that lumbar puncture should be performed in cases of uræmia, whether coma, convulsions or merely severe headache be the predominant feature. The presence of a high blood pressure would be helpful as indicating the advisability of lumbar puncture.

On the above hypothesis of the origin of uræmia it is somewhat difficult to account for the material improvement that sometimes undoubtedly follows venesection, for inasmuch as venesection lowers the blood pressure, at any rate temporarily, it would act in opposition to the compensatory mechanism which maintains the cerebral circulation in the face of the high intracranial tension, and so should be a harmful rather than a beneficial procedure. It is possible, however, that the benefit which sometimes follows its employment is due to the relief of the failing heart with right sided distension. It would further facilitate the outflow of venous blood from the brain and so help to diminish intercranial tension. Moreover, a free venesection removes a material fraction of the total blood, and the present paper in no way disputes the presence of an abnormal and toxic blood in uræmic conditions.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

OPERATION FOR BRANCHIAL CYST OF NECK.—Mr. T. P. LEGG operated on a woman, æt. 37. She had noticed the lump for some months, and during the last few weeks it had got rapidly bigger. Practically no inconvenience had been caused by the swelling. She had no difficulty in swallowing or trouble with breathing. Beneath the right sterno-mastoid, on a level with the hyoid and upper part of the thyroid cartilage there was a large ovoid tumour, the long axis being placed horizontally. The tumour was as big as a duck's egg; it was quite smooth, movable on the deeper structures, and gave distinct fluctuation. The skin was normal, and no evidence of pressure effects on adjacent structures was found. Mr. Legg said that a diagnosis of branchial cyst was made: first, on account of the situation of the tumour beneath the sterno-mastoid and on the level of the hyoid bone; secondly, it was apparently a fluid swelling, and he might also mention here that the carotids were deep to the tumour. It was unlikely to be a tuberculous abscess due to disease of the glands, because there were no other evidences of the glands being affected, and it would be most unusual to find an abscess of this size due to tuberculous disease of one gland alone. The periphery of a tumour should always be carefully examined for nodules or gland-like lumps; if such were present they were a valuable aid in diagnosis. An aneurysm of the carotid could be excluded because the

(*d*) "Diseases of the Kidneys," Nothnagel's "Encyclopædia," American Edit., p. 103 and iii.

swelling was fluid and did not pulsate. A transverse incision, four inches long, was made along the axis of the tumour, which was dissected out without much difficulty. The sterno-mastoid required partial division, as it and the tumour were closely adherent. The carotid sheath was detached, and at the upper end of the tumour a band-like process was tracked upwards and ligated before being divided. During the dissection, the cyst was ruptured, and opaque yellow liquid containing cholesterin cystals visible to the naked eye, escaped. The wall of the cyst was about one-eighth of an inch thick, and smooth internally; on the outer side it was rough. The sterno-mastoid was united by two or three mattrass sutures, and the wound closed, a drainage tube being put in at the posterior end of the incision. The fluid was examined at the end of the operation, and contained squamous epithelium, degenerated cells of various sorts, including leucocytes and cholesterin crystals. Mr. Legg remarked that as regards the operation, a transverse incision was best. It gives plenty of room, and if made slightly curved, a flap can be dissected up in order to increase the exposure of the deeper parts. Moreover, the scar becomes practically invisible in the course of time. In suturing these incisions, it was always advisable, he considered, to put in two or three stitches which unite the cut edges of the platysma and deep fascia. By doing so, the margins of the skin incision were closely approximated, and the sutures in the skin can be removed in four or five days. Thus very often the stitch marks are invisible. The removal of these cysts, he pointed out, was not always as easy as in this case. They were always in close contact with the great vessels and nerves of the neck, and sometimes the cyst passed between these structures. Hence, in separating the deeper parts, the surgeon has to keep close to the cyst, and see exactly what he is doing. The band-like process required tracing as far as possible and ligating. It contained the remains of a branchial cleft from which the cyst was derived by dilation of an unobliterated portion. Which cleft this particular cyst was derived from was not very certain, because it was impossible to make out the exact relations of the cyst to the vessels and nerves. They were not very rare tumours. During the last two or three years there had been three or four cases in the hospital. One patient was a child, æt. about 13, and there had been two other young adult patients. Subsequently a microscopic examination of the cyst wall in the present case showed the lining epithelium to be squamous, thus confirming the diagnosis.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, June 30th 1907.

The Treatment of Syphilis.

In treating syphilitic patients, certain restrictions should be observed in the employment of the mercurial treatment. Of these restrictions, some depend on the form to be prescribed, in which account should be taken of the extreme susceptibility of certain organs such as the stomach, intestines, bladder, while others concern the dose, which should be proportioned to the resistance of the subject, and to the permeability, more or less diminished, of the emunctories.

The best form of application, says Prof. Belugon, is hypodermic injection of the soluble salts. The intramuscular introduction of the drug is the most exact and precise method, which also allows supervision of the doses employed. The gastro-intestinal disorders which frequently follow the use of pills or mixtures expose neuropathic patients to danger.

As to mercurial ointment frictions, they have the fault of being difficult to control as to the dosage. Sometimes the patient will use too much, at others the quantity will be insufficient.

Insoluble injections and particularly those of calomel should be reserved for extreme cases where rapidity is necessary, in ocular syphilis, etc., and in tabetic patients showing symptoms of cerebral disturbance, persistent vertigo, epileptic attacks, aphasia, and hemiplegia.

Of the soluble salts, benzoate or bichloride of mercury are the most easily absorbed.

The cure should be divided into three or four series of twelve injections each with a corresponding interval of rest.

Vegetations of the Genital Organs.

An easy method of treating isolated and pedunculated vegetations is to place on the papilloma a small quantity of resorcin by means of a moistened hair pencil, and cover with a piece of gauze. The application is renewed each day until the vegetation is dried up.

Where the vegetations are numerous and sessile the following mixture is painted over them.

Resorcin	drachms 2.
Collodion	ounce 1.

Two or three applications are sufficient. To avoid a return of these troublesome excrescences, the patient should bathe the parts in a solution of resorcin, ½ per cent. and apply the following powder:—

Carbonate of zinc	drachms 2.
Sub-nitrate of Bismuth ..	drachms 2.
Resorcin	drachm ½.
Talc powder	ounces 3.

Infantile Eczema.

At the last meeting of the Academie de Medecine, M. Variot, of the Children's Hospital, said that infantile eczema was rapidly and favourably influenced by subcutaneous injections of isotonic sea-water. In three fourths of the cases the treatment was entirely successful. After the first two or three injections the eczema became inflamed, with abundant weeping, after which an improvement set in, the scales became detached, and a cure followed. Sometimes there is no reaction, and in such cases the improvement is almost instantaneous, and the lesions begin to pale the following day. One ounce of this sea-water is injected every two or three days. According to M. Variot, no other treatment gave such favourable results.

GERMANY.

Berlin, June 30th. 1907.

Extraordinary Results from a Dagger Thrust.

At the Medizinische Gesellschalft Hr. H. Hirschfeld showed a young man who, several months before, had received a dagger thrust in the right cheek below the malar bone. Immediately afterwards he could not speak, had a difficulty in swallowing, and the right half of his face drooped. The wound healed slowly, as a salivary fistula formed in consequence of a wound of the parotid. Now the following changes were noted:—The right eyelid and pupil were narrowed, the right half of the face did not perspire, the tongue lay obliquely, the whole right half of the cavity of the mouth was without sensation; the larynx deviated to the right on swallowing, the right vocal cord was immobile in the position of that of the dead body, the right side of the fauces and larynx had no sensation, so that there was frequent swallowing. Pressure on a certain spot of the right side of the neck set up coughing, the right sterno-cleido-mastoid and platysma were atrophied. It was a case therefore of injury of the seventh, ninth, tenth, eleventh and twelfth cerebral nerves, as well as of the sympathic at the base of the skull. Whether it was possible to unite the nerves by suture he had not decided.

At the Congress of the German Society for Orthopædic Surgery, Hr. Karch, Aachen, described his misfortunes and successes in

Transplantation of Tendons (300 Joints).

He put forward the following conclusions:—The positive success of the operation stands and falls (1) with the exact indication; (2) with the operative technique; (3) with the technique as regards bandaging; (4) with the quality of the after-treatment. Flaccid paralysis affords the most frequent indication for operation, and shows the finest results. The limits of the indication are very wide. If an extensive flaccid paralysis has existed for more than ten years transplantation only rarely shows good results. It is better then as regards the lower extremities to perform arthro, teno, or fasciodesis. Caution is required in the winter time if chilblains are present. Transplantation in spastic paralysis requires much experience in knowing how far to go; an excess in yielding power never leads to an improvement of the condition. Simple plastic lengthening is often sufficient. In complicated spastic paralysis of the upper extremities the results obtained by operation are not always satisfactory. It is hopeful that treatment with implantation of the nerve will give better result. Peripheral paralysis and loss of power from traumatism are satisfactory objects of treatment. Contractions with flexion are efficiently met by exact transplantation. Advancing cerebro-spinal affections should never be treated by transplantation.

2. The plan of operation must be simple. Periosteal transplantation is to be preferred; that of tendon to tendon along with this is proper, and is sometimes the only way to success. Functional independence is best assured by periosteal implantation. In transplantation from tendon to tendon some of the associated muscle should be used to give power. Transplantation of bone and the boring of bony canals must be avoided. Button-hole implantation is the best, and sublimate silk for the suture material. Of course, the limb must be put right, and if necessary the tendon shortened before the implantation is done. On the dorsum of the foot, in order to avoid pressure gangrene any tense tendon bridges are to be removed from the periosteum by means of a silk loop, so that they run through a sort of tunnel of silk. For shortening, folds should be made and fixed; for lengthening, step or surface incisions. Very poor tendons may be shortened if they are first sutured to the tendon of an associated muscle that is in function. "*Deshabiller Pierre pour revêtir Paul*" is allowable under some circumstances, when an important function can be gained by the sacrifice of one less important. Stitch abscesses were rare and did no harm. Suppuration is very rare, and does not prejudice the result. They were to be avoided by immaculate asepsis, arrest of bleeding, and exact skin suture. Flat shaped muscles were not to be transplanted.

3. At the close of the operation the joint must be placed in the desired position; dressing was not advisable during the hardening of the covering. The dressing must be cut open if when the rubber bandage was removed the circulation did not return promptly. The dressing should remain on for eight weeks. There was no change of dressing when the skin suture was of silk and recovery normal.

4. The after-treatment is important, for a permanent success conscientious massage must be carried out. Further, active, passive and later, resistance movements would be necessary, or the wearing of a portable apparatus, as well as the employment of physical curative measures.

Transplantation of tendons was the most important novelty in the treatment of paralysis. Along with this, and sometimes taking its place, would be the still incompleted method of nerve grafting. Both were justifiable; for the majority of cases tendon transplantation would remain sovereign.

AUSTRIA.

Vienna, June 30th, 1907.

Cataracta Complicata.

KONIGSTEIN showed a male patient to the "Gesellschaft" with an old standing cataract which he considered inadvisable to operate on, as the sensation of light was probably lost and no good would result. This case was before the members six years ago, when the same opinion was formed.

The present condition is rather peculiar. The anterior chamber is filled with a mass that glistens and glitters like gold when light is thrown on it. He considered this due to granules and scales of cholesterin which had become deposited in the membrani Descemet lining the interior of the cornea, or it may be blood colouring deposited in the cornea itself. From this it would seem that the capsule of the lens had burst, exuding the contents which have taken on a retrogressive metamorphosis forming cholesterin, or perhaps the effused blood has undergone the change and produced this phenomenal body.

Scapular Rhonchus.

Lotheissen showed a peculiar case of loud crackling under the right scapula, which could be heard when standing at a considerable distance from the patient. There was no tuberculosis, or muscular atrophy in the serratus muscle, to account for the strange phenomenon. He considered the change to be due to a dry proliferating bursa which could not be cured without operation.

Cystic Widening of Ureters.

Kapsammer next showed a case that had been diagnosed by the cystoscope as a morbid condition of the urinary apparatus. Three weeks ago he performed the abdominal section and found both ureters distended into two cysts, which apparently were congenital defects, and not morbid as at first presumed. This wide condition extended far up the ureters, which were healthy and otherwise in good condition. He pointed to this as an example of an unavoidable error.

Pes Varus.

Semeleder reported the success he has met with by his method already described of treating talipes varus in the paralytic form which many are sceptical about. He exhibited photos of sixty cases before and after treatment, which are convincing of success, whatever the method may be by which he had accomplished it. The idea carried out in his apparatus is to prevent the antagonism of the healthy muscles distorting the member by tearing the paralytic muscle too far and destroying its functional activity, which he considers the sole cause of the anatomical deformity. If the paralysed muscles are physiologically checked, atrophy commences, while the strong muscles with the weight of the body complete the destruction. His object, therefore, is to place the action on the paralysed muscle and leave the strong muscle to atrophy.

Photos of two cases presented were of considerable interest, as the original photos and the present condition were marvellous contrasts.

Alberle challenged the method as having a special advantage, for he has treated similar cases with a wedge ½ to 1 centimetre with perfect success, and they never required to put the patient to bed. This destroyed Semeleder's assurance that his boot had any influence in strengthening the muscles of the leg. The weight of the body is not all that is to be considered for this correction, or Beely's apparatus would be quite sufficient. If the talipes is not severe, the least painful and more effectual method is the manual correction which can be done by the mother or the nurse. Semeleder replied that many of the other apparatuses required the patient to remain in bed, but his did not, as the patient could move about with advantage; with his apparatus the legs would be corrected in two weeks, with other forms the patient may wear them years without any visible improvement.

Physiological and Pathological Circulation.

Benedikt described the changes in the circulation, remarking that cramp in both of the large crural arteries may occur at the same time, thus showing a homonymous pulse as if a normal condition existed. If the carotid pulse is greater on one side than the other, so is the radial pulse of the former less than the latter, *i.e.*, the sides are inverted. This is not a constant anatomical fact, but is usual. Basch found different pressures in homonymous vessels. The prodromal symptoms of apoplexy can be detected by any departure from this anatomical relationship.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

THE ASSAULT ON DR. CARSWELL, GLASGOW.—Purvis, who assailed Dr. Carswell in the streets of Glasgow with a revolver on April 16th last, was brought before Sheriff Glegg on June 22nd. The Procurators Fiscal stated that he had been examined by experts in lunacy on several occasions since his incarceration, and had been certified as of unsound mind, and was therefore unable to plead to the indictment. An agent who appeared for Purvis asked the Sheriff to take a plea of not guilty. The Sheriff, however, following the precedent in the Cumnock poisoning case, reserved the matter for the consideration of the High Court.

EDINBURGH ROYAL INFIRMARY.—At their meeting on June 24th, the managers appointed Dr. Douglas Chalmers Watson, F.R.C.P., to be an assistant physician, and Mr. William J. Stuart to be an assistant surgeon to the Institution. There were a number of candidates for both posts.

SIDLAW SANATORIUM, DUNDEE.—During the year, 115 patients have been treated. Of the discharges, numbering 79, 18 were unsuitable cases; of the 61 remaining, the disease was arrested in 34, markedly improved in 24, stationary in 3. The medical superintendent has kept in touch with the patients who have left, and reports that at the end of the year 90 per cent. of the arrested cases were in good health, and 70 per cent. were at work. Of similar cases discharged last year, 85 per cent. continue well. Such results are highly satisfactory. The sanatorium is kept up by public subscription, a small sum being received from the patients. The cost per patient is 38s. per week.

THE LATE DR. HOWDEN, HADDINGTON.—The death took place on the 25th ult. of Robert Howden, M.B., who represented a family of East Lothian doctors which had been connected with the county for nearly a century. He was the grandson of Dr. Thomas Howden, who was a partner of Dr. Welsh, father of Mrs. Carlyle. His own father, Dr. Thomas Howden, died in 1900 at the age of 89, and a brother, Dr. Thomas Howden (*tertius*), died in 1878. Dr. Robert, who fell a victim to pneumonia, held a number of local medical appointments, and had an extensive practice. He is survived by a widow and two children.

LETTERS TO THE EDITOR.

LIVINGSTONE COLLEGE AND MEDICAL MISSIONARIES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I desire to thank you for your kind reference to Livingstone College in your last issue, but hope you will permit me to offer some explanation of the system which is adopted at this College.

Let me say in the first place that I agree with you most fully that it is in the highest degree desirable that men going abroad as missionaries should have the best medical qualifications. The Church Missionary Society, of which I was formerly a medical missionary, and am now physician, has sent to the Mission Field a number of medical missionaries of the best type, many of them possessing exceptional scientific qualifications. This is as it should be, and I desire to see the list of medical missionaries largely increased.

There is, however, another problem wholly different from this which has to be considered. Many missionaries are called upon to work in isolated stations far from qualified medical or surgical help. At any moment they or their fellow missionaries or families may be struck down by some rapidly fatal illness or accident, which can have but one issue unless they possess such medical knowledge as would enable them to identify and cope with these ailments. Livingstone College men have been able in many cases to preserve their own lives and that of other Europeans, and I have little doubt that scores of lives have been thus saved.

Again, men so placed often find themselves amongst ignorant natives who suffer unspeakable tortures from neglected wounds, abscesses and ulcers, whose sufferings are intensified by the methods of so-called witch-doctors. Common humanity will not allow a civilised man, much less a Christian man, to see such things, which simple aid can relieve, and refuse to render that aid. Yet if these things are to be done training must be given. Previous to the existence of Livingstone College men attended the ordinary hospitals and picked up what knowledge they could, and there was great danger that they might undertake treatment which they were utterly unfitted to carry out. At Livingstone College students are not only taught carefully what they may do, but what they must not attempt, and we have never heard of any serious mistake being made. Besides this the students sign a declaration that they will not call themselves medical missionaries or assume the position of qualified medical men. What more can we do? What less can we do? You in common with the other chief organs of the medical profession have most generously supported us in the past. I venture to hope that we may rely upon your continued support.

I am, Sir, yours truly,
CHARLES F. HARFORD, M.D.,
Principal of Livingstone College.

Leyton, June 24th, 1907.

THE EXCLUSION OF SCOTCH AND IRISH DIPLOMATES FROM THE MAJORITY OF LONDON HOSPITALS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The outspoken letter in your issue of June 19th deserves careful attention. The majority of the large English hospitals, both in London and the provinces, exclude both Irish and Scotch medical diplomates from their honorary medical staffs. This disqualification has been placed on the laws of hospitals in past times when possibly there were not so many qualified medical men educated in Scotch and Irish colleges and universities. Anyway, it constitutes a standing injustice to many honourable and highly qualified men.

What does the boycott mean? A very slight analysis will, I think, show that the matter is simply one of class privilege. It is obviously advantageous to holders of English diplomas and degrees to have a monopoly of these valuable professional posts. It is equally advantageous to the colleges and universities that grant the special qualifications whereby alone the monopolist appointments may be secured. But what about the men and the colleges that are shouldered out by the monopolists?

If the public were fully informed of the facts of the case, it is hardly likely that this injustice would long be permitted to continue. A considerable proportion of the governors of hospitals are attended medically by Scotch and Irish diplomates and graduates. What would governors say if the men who are considered good enough to attend themselves are not permitted to attend hospital patients?

Let us, at any rate, have the full light of day upon the situation. If the English colleges can show they have good ground for maintaining their monopoly, by all means let them keep their privilege; otherwise, let us have some sort of equality of opportunity afforded to all duly qualified medical practitioners within the United Kingdom.—Yours faithfully,

A SCOTCH F.R.C.S.

Manchester, July 1, 1907.

THE council of the London School of Medicine for Women have received from Mrs. Godfrey Walker, of Conisborough Priory, Yorkshire, the munificient gift of £20,000 in aid of the endowment of the school.

THE TEACHING OF PHYSIOLOGY.

To the Editor of The Medical Press and Circular.

Sir,—With regard to the admirable letter from your Dublin correspondent I trust the matter will be discussed fully in your columns. It has always seemed to me personally that it is sheer waste of time to demand of medical students a knowledge (!) of advanced physiological experiment and theory. The only possible excuse for making such a demand appears to be the intellectual training of the student, but that could surely be obtained by other methods more likely to help him in the after battle of professional life.

I am, Sir, yours truly,
Duns Scotus.

Colwyn Bay, July 1st, 1907.

OBITUARY.

SIR WILLIAM TENNANT GAIRDNER.

Sir W. T. Gairdner, K.C.B., LL.D., M.D., died on Friday last at the advanced age of 82. He had been laid aside from active work through failing eyesight for a number of years past, and for several years had suffered from cardiac disease. His death, however, was sudden in the extreme. Up till a day or two ago he was able to take his usual drives into the country, and on the morning of the day of his death he was able to receive an old friend who had come into Edinburgh to attend the Old Residents' Dinner, and to send by him his apologies and regrets for inability to be present at that gathering. Before the message, however, could be conveyed, Sir William had passed away. Deceased was born in 1824, in Edinburgh, his father being the late Dr. John Gairdner, a president of the Royal College of Surgeons, Edinburgh. He graduated M.D. in 1845, and for his thesis, which was on the subject of "Death," he was awarded a gold medal. After graduating, he travelled abroad as physician to the Earl and Countess of Beverley, and returned in about a year's time to Edinburgh, where, at the early age of 24, he was appointed pathologist to the Royal Infirmary in succession to Hughes Bennet. Soon after this, in 1853, he began to lecture on the Practice of Physic in the extramural school, and continued his class until his appointment to the Chair of Medicine in the University of Glasgow in 1862. Sir William Gairdner's interests at that time were much directed towards matters of sanitation and public health. In the year of his election to the Glasgow professorship, he published an important work on "Public Health in Relation to Air and Water," which was a record of the first course of lectures on sanitation ever delivered in Scotland. This attracted the attention of the municipal health authorities to Dr. Gairdner, and the late Mr. John Ure (afterwards Provost of Glasgow) entered into negotiations with the writer with the object of securing his assistance in carrying out a scheme for establishing a health department in the city. After some demur, lest the proposed work should interfere with his University duties, the Professor accepted an appointment as Medical Officer of Health for Glasgow. He was the first occupant of that office, and held the post for nine years from 1863. During this time he successfully combated several severe epidemics. These, along with a threatened outbreak of cholera in 1866, led the new Medical Officer to make a systematic investigation of the conditions of housing in the slums, and he was sent to Paris to report on the improvements then being carried out by Napoleon III. in the French capital. These investigations, added to his previous experience of conditions in Glasgow, proved of valuable assistance in connection with the first Municipal Improvement Act, which revolutionized the sanitation of the city. Professor Gairdner occupied the Chair of Medicine in Glasgow for nearly forty years. He resigned in 1900, because of failing vision, which prevented his keeping abreast of medical literature, and also debarred him from microscopic work and bacteriological investigation. After Lord Kelvin's retirement, Gairdner became "Father of the Senatus." He was greatly esteemed as a teacher, and as a clinician he justly enjoyed the highest reputation. He was the recipient of many professional honours: Honorary Physician to the King in Scotland, LL.D.Edin., M.D. (honoris causa) Dublin, Honorary Fellow of the Royal College of Physicians of Ireland. He was also a Fellow of the Royal Society, of the Royal Medical and Chirurgical Society, and an honorary member of many other learned bodies. He was President of the British Medical Association on the occasion of its visit to Glasgow in 1888, and he also filled the position of President of the Royal College of Physicians of Edinburgh. He was made a K.C.B. in 1898. Sir William Gairdner's medical writings were numerous. He was greatly interested in diseases of the heart, and his graphic methods of recording physical signs are well known. He published a volume on "Clinical Medicine" in 1862, and delivered the Morison Lectures on "Insanity" in 1879. "The Physician as a Naturalist" came from his pen in 1889. Sir William Gairdner was a man of varied talent; it is said of him that he could have filled almost any chair in the University. He never lost his interest in affairs medical, and even his own last illness afforded him matter for professional study. He married in 1870, and is survived by his widow, four sons, and three daughters.

JOHN M. HARRISON, M.R.C.S., L.S.A.

It is with deep regret we announce the death of Audlem's oldest medical practitioner, Mr. John Mare Harrison, M.R.C.S., on June 18th, at his residence, after several months' illness. The deceased gentleman was born at Leek, Staffordshire, on November 6th, 1817, and was the youngest son of the late Dr. Gallimore Harrison. Previous to going to Audlem, Dr. Harrison practised for several years in Burslem. His practice in Audlem extended 50 years, and during that time he was a kind friend to the poor, and highly esteemed by all. He was a staunch Churchman, an ardent supporter of the schools, and always lent a helping hand to further any good cause. Much sympathy is felt for the two daughters, Mrs. Jackson and Mrs. Greaves.

WILLIAM SUGDEN WRIGLEY, M.B., Ch.B. Vict.

We regret to announce the death on June 22nd, of Dr. W. S. Wrigley, of Rawtenstall, at the age of 27. Two years ago he took up practice in Nelson, and he had only recently been married. He was educated at Owen's College, and graduated M.B., Ch.B. in the Victoria University, with first-class honours, in 1902, and he later served as House Surgeon in the Manchester Royal Infirmary.

SPECIAL ARTICLE.

MEETING OF THE ROYAL SANITARY INSTITUTE.

The Royal Sanitary Institute held its annual meeting last week in Trinity College, Dublin, with Sir Charles Cameron as President.

In his inaugural address the President detailed the development of sanitary administration in Dublin during the past half-century. Thirty-seven out of every 100 families in Dublin occupied each a single room. In many English towns not 10 per cent. of the families were occupiers each of a single room. The poverty of a large proportion of the people was shown by the fact that whilst about 16 or 18 per cent. of deaths in English towns occurred in workhouses, hospitals, and other institutions, more than 40 per cent. of the deaths in the City of Dublin take place in these institutions. It was not fair to compare a city which, as in the case of Dublin, contained an abnormally large poor population, with cities like London, in which there were higher standards of wealth and comfort. In 1906 the expenditure of the Public Health Committee amounted to £15,593. A large proportion of the expenditure was in relation to the maintenance of fever patients, payment for notifications of infectious diseases, fees to the registrars of Cemetery Boards, working the Act relating to the street trading of children, contributions towards the maintenance of open spaces, proportion of law agents' and accountants' expenses, expenses in connection with the Contagious Diseases (Animals) Acts, and in providing dwellings for the working classes. The Corporation had expended £485,000 in clearing unhealthy areas, and a very large sum in the erection of baths, wash-houses, refuse destructors, abattoirs, &c. The Corporation of Dublin had expended £345,000 in providing dwellings for the working classes, and a large sum in the erection of baths and wash-houses, abattoirs, and a disinfecting house refuge for persons whose residences were undergoing disinfection or who had been in contact with cases of infectious disease. A sum considerably over half a million had been expended in main drainage works, designed to free the River Liffey from pollution and to prevent the blocking of the street sewers.

The various forms of tuberculosis caused a large proportion of the deaths which occurred in Dublin. In 1906 there were 937 deaths from tuberculosis of the lungs, or in the ratio of 3.15 per 1,000 of the population. The deaths from all forms of tuberculosis numbered 1,386, or in the ratio of 4.71 per 1,000 persons living. It was remarkable that whilst all other diseases, of which the *materies morbi* consisted of pathogenic micro-organisms, had greatly declined in Dublin, tuberculosis, which belonged to that class, continued unabated. The three great problems demanding solution are: How was the terrible mortality of children to be lessened? How were the ravages of tuberculosis to be minimised? How were the very poor to be provided with healthy dwellings?

The paper was discussed by Mr. H. O. Searles Wood and Sir John Moore.

On the 26th, the President read a paper on "Sanitary Science and Preventive Medicine."

Mr. C. L. Birmingham, M.D., denied that they in Ireland were in the rear as regards the laws of public health. He denied also that the sanitary laws in some places were practically a dead letter. The sanitary laws were being carried out instinctively by the people. He had never known a people so ready to follow advice on sanitary matters, but they would not be driven. He had no difficulty in establishing a system of voluntary notification of tuberculosis. The vaccination laws were carried out with the greatest promptitude. So great was the burden thrown on the medical officers that they were bound to close their eyes to a great deal. He was obliged absolutely to ignore the Home Office queries.

Among those who took part in the discussion were Drs. Magennis, Agnew, and Flinn, Mr. S. G. Moore, Mr. J. Lindsay, and the Registrar-General for Ireland.

The following resolution was passed:—"That this Conference is of opinion that it would be desirable to have county medical officers of health with a sufficient staff of qualified sanitary inspectors appointed for Ireland, and that the Council of the Royal Sanitary Institute be requested to take steps to urge this opinion upon the consideration of the Government."

Dr. McWeeney read a paper on "The Role of Sanatoria in Checking Tuberculosis," which was discussed by Sir Charles Cameron, Drs. Hanaford, Antony Roche, and Willoughby, and Mr. E. T. Hall.

On June 27th, discussions took place on "Housing of the Working Classes," and "Sewage Disposal," the subjects being introduced by Mr. P. C. Cowan and Mr. W. Kaye Parry respectively.

On the 28th, Sir John Moore read a paper on "The Climatology of Ireland in Relation to Public Health," in which he maintained that the climate of Ireland, generally, is the most temperate in the world, and the most conducive to health and longevity, and with efficient sanitary organisation and cleanliness in the homes, the island would rank as one of the healthiest countries on earth.

Sir Charles Cameron said there were very few climates, on the whole, superior to that of Ireland. The principal feature was its equability. There was only about ten degrees difference between the mean winter and summer temperatures. A low death-rate was usually co-incident with a cool summer and a mild winter. He dreaded a hot summer and a cold winter, for there was no greater fallacy than that a green Yule makes a fat churchyard.

Mr. Rideal, D.Sc., F.I.C., read a paper on "Disinfection Considered from a Medical, Chemical, and Bacteriological Standpoint." Both he and Mr. A. E. Moore, M.B., B.Ch., R.U.I., Queen's College, Cork, agreed on the necessity for the standardisation of commercial disinfectants; and Dr. S. G. Moore, M.D., Medical Officer of Health, Huddersfield, said that the great majority of the disinfectants sold under fancy names, and, of course, at fancy prices, were, to a large extent, ineffective. Ordinary daylight, fresh air, high temperature secured by means of steam, and soap and water were agencies which without any chemicals at all were absolute and complete disinfectants.

The Registrar-General for Ireland (Mr. Matheson) quoted some interesting statistics showing the relation of earth temperature to deaths from diarrhœal diseases, and also spoke of the close relation between the decrease of temperature and increase of mortality from diseases of the respiratory organs.

The Chairman said if the natural agencies of disinfection, such as sunlight, heat, &c., were extensively utilised, tuberculosis would have disappeared from the country in fifty years.

At the conclusion of the proceedings votes of thanks were passed to the Lord Lieutenant and the Countess of Aberdeen, to the Provost and Fellows of Trinity College, to the Lord Mayor, to the directors of Guinness's Brewery, the trustees of the Iveagh Trust, to the Dean of St. Patrick's Cathedral, to Colonel Plunkett, Director of the Science and Art Museum, Alderman Cotton, and others, to Surgeon-Colonel Dr. Edgar Flinn, and Mr. W. Kaye Parry, and also to Sir Charles Cameron.

REVIEWS OF BOOKS.

TEXT-BOOK OF PATHOLOGY. (*a*)

The value of this text-book is well shown by the fact that in the nine years since it first appeared, five editions have been issued. The author has succeeded in introducing many new facts, and in revising the text in many instances without materially adding to the size of the book—a matter of some importance in a volume of this character. The chapters on "Inflammation and Immunity," have been carefully revised, but the author's determination to avoid any lengthy details of pathologic physiology, while doubtless unavoidable, necessitates the omission of many important researches. This particularly refers to the recent experimental work on the pathology of cancer, which hardly receives adequate treatment in this work. Many of the chapters are excellent, particularly that on "Diseases Due to Bacteria," that on "Animal Parasites," which has been largely re-written, and the chapter on "Urines." As is perhaps unavoidable, one finds unexpected omissions. For instance, there is no mention of the pyloric stenosis of infants, the pathology of which has been so much in question, and little is said of some other important subjects, *e.g.*, carcinoma of the kidney is dismissed in a few lines, gastric carcinoma is discussed very shortly, and "hernia" and "peritonitis" (particularly the latter in the pathology of which much work has been done of late) are hardly up to the level of much of the rest. An admirable appendix containing details of pathological and bacteriological laboratory work is introduced, and will be found of great value. The book is well got-up and printed, although the proof-reader has passed many misprints in the article on "Endothelioma." Many illustrations and seven full-page colour plates add to the value of the edition, though it is to be hoped that such an illustration as that of "syphilitic cirrhosis of the liver" (page 611) may be eliminated in future editions

---

(*a*) "Text-book of Pathology." By Alfred Stengel, M.D. Fifth Edition. Pp. 935. Philadelphia: W. B. Saunders and Co. 1906.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT OBSTETRICAL LITERATURE.

Chorea During Pregnancy.—Shaw (*Journ. Obst. and Gynæ.*, 1907).—This is a report of eleven cases of chorea of pregnancy. The first two cases were treated on traditional lines with unsatisfactory results. It was then decided to try anti-toxin treatment, by which patients were put on a milk diet and elimination increased. In nine cases so treated the best results were secured. The idea underlying the experiment was that the toxæmia of pregnancy lowers the resistance of the nervous system, and puts it in a state of heightened irritability, so that it responds to stimulæ, chemical and emotional, &c., which would not otherwise produce any result perceptible by ordinary clinical methods of observation. Based on this hypothesis, the treatment aims at (1) removing the pre-disposing cause; (2) removing the determining cause; (3) treating the symptoms, if necessary. The author's conclusions are: (1) The chorea of pregnancy, like other choreas is due to a toxin which appears to be identical with, or closely to resemble, that of acute rheumatism; (2) it affects human subjects under two circumstances, both of these being characterised by instability or irritability of the nervous system, namely, childhood and pregnancy; (3) the cause of the instability or irritability of the nervous system in pregnancy bringing it down to the level of childhood, is the toxæmia of pregnancy; (4) in the chorea of pregnancy, therefore, it is more important to remove the pre-disposing cause than to apply merely symptomatic treatment; (5) the treatment must be eliminative as in the other toxæmias of pregnancy; (6) the pregnancy should not be arrested, as a rule, as this is generally unnecessary and harmful to the patient, as well as to the child. F.

Puerperal Peritonitis Treated by Abdominal Section.—GORDON (*Journ. of Obstet. and Gynæ.*, June, 1907).—This is a report of ten cases treated in the Monsell Fever Hospital, Manchester. All the patients were in a very critical condition when admitted to hospital and operated on, and many were regarded as being in a hopeless state. Of the ten cases four died and six recovered. The conditions found on opening the abdomen consisted of general peritoneal infection, discharging pus tubes and abscesses of ovary or uterine wall, abscesses in Douglas' space, cellulitis, and decomposing placental remains inside uterus, most of these conditions were present in each case; the discharging pus tubes being common to all. Cultures made from the peritoneal fluid showed streptococci alone in four cases, streptococci with bacilli coli communes in three, streptococci and gonococci in two, and in one case cultures taken from the blood during life showed streptococci only, while those from the uterus gave streptococci, bacilli coli and staphylococci. In only one case was flushing of the peritoneal cavity resorted to, but in this case the writer attributes the patient's recovery to it. However, he is of opinion that, as a rule, it is best not to flush or even sponge the peritoneal cavity at all, but to rely rather on free drainage at the most dependent part, with subsequent propping up of the patient in a sitting position, and the subcutaneous injection of saline solution with or without anti-streptococcic serum and adrenalin. Calomel is almost invariably administered on the second or third day. Cases where placental masses remained in the uterus, were curetted with a large sharp curette, swabbed with pure izal, or corrosive sublimate solution and packed with gauze. F.

The Treatment of Post-partum Hæmorrhage, with a New Method of Hæmostasis.—Stowe (*Surg., Gyn., and Obstet.*, June, 1907).—After reviewing the prophylaxis of post-partum hæmorrhage, the writer says that in cases where massage of the uterus and expulsion of clots with emptying of a distended bladder fail to control hæmorrhage, and where from atony of the uterus, the organ lies in the pelvis like an empty sac, with its walls soft and offering no resistance to the hand, he has with great satisfaction tried a new method of hæmostasis. As the patient is bleeding profusely at the time something must be done immediately so he grasps and firmly kneads the fundus with one hand at the same time pressing it down into the inlet. The other hand, encased in a sterile glove, is passed into the vagina up to the cervix, the fingers seizing as much of the cervix and lower uterine segment as possible. The hand is then forced far into Bandels ring until the fundus is reached. The internal hand remains thus outside the uterine cavity throughout the operation. If sufficient pressure be used the internal hand can be forced well into the fundus and past the contraction ring, pushing the cervix and lower uterine segment before it against the walls of the fundus. This obliterates the cavity of the uterus and brings direct pressure and compression to bear against the sinuses and open vessels. The position of the internal hand or fist in the fundus, yet outside the uterus, has a marked effect in stimulating contraction, especially when aided by brisk massage and by inverting the lower portion of the uterus into the upper direct pressure is brought to bear by the hand against the uterine arteries, and the supply of blood is in a great measure shut off. If arrest of hæmorrhage is in great part obtained, and the uterus contracts poorly, an intra-uterine douche at 115 F. is given. If the bi-manual compression and the douche produce only temporary hæmostasis further delay is dangerous and recourse should be had to the utero-vaginal tamponnade. F.

Asepsis during Abdominal Operations.—Fritsch, at the meeting of the German Gynæcological Congress at Dresden (*Zentralblatt für Gyn*, 1907, No. 25) said among other remarks on this subject that the efforts to produce asepsis through the course of an operation may be divided into the following parts:—(1) The sterility of the hands; (2) The sterility of the field of operation; (3) The prevention of pollution during the operation. The importance of preserving the hands has led the author to give up the hot-water—alcohol-sublimate disinfection for the soap—spirit disinfection of v. Mikulicz. Rubber gloves are necessary. Further it is most important whenever an unclean wound is touched or during a rectal examination or vaginal exploration when there is discharge, for example, carcinoma, that rubber gloves should always be worn. Operating with perforated or torn gloves is careless and irrational. Repeated rinsing of the hands during operation in sublimate and sterilised water is to be recommended. As regards the asepsis of the field of operation we have to deal with three regions, (*a*) The skin of the abdominal wall; (*b*) the vagina, and (*c*) the vulva with the anus. For this also the soap-spirit disinfection is admissible. The speaker has now adopted Döderlein's proceeding, not because his results formerly were bad, but because one is ready sooner without allowing the patient to become cold. The abdomen is first rubbed over with benzine, then with a gauze wipe, soaked in tincture of iodine, and after this has dried it is smeared evenly all over with a solution of rubber Döderlein's "Gaudanin," with the apparatus which has been constructed for this purpose. When the rubber is powdered over with sterile chalk the preparation is finished. The bacteria deep in the skin are best overcome with the tincture of iodine, while they are kept away from the wound by the rubber membrane. Further, in order that the tissues may preserve their vitality and their power of re-acting to infection, it is necessary that they should be protected; therefore the operating should be quick and skilful. The speaker also recommended Stœckel's speculum for protection of the abdominal wound. The finger should be employed for the separation of intestinal adhesions, adherent cysts and tumours. The intestines should never be allowed to come outside the abdominal cavity. This is easily prevented in the pelvis high position by putting in a large compress. This absorbs blood and even pus so well that after its removal wiping out the cavity may be omitted. To prevent ileus and adhesions it is necessary to cover over every raw surface in the peritoneal cavity. Pfassuenstiel's incision combines all the advantages of ventral laparotomy with the advantages of the vaginal operation; for example, the good prognosis which is associated with the small vaginal opening into the peritoneum. The injuries to the bladder which so often make patients permanent invalids after vaginal cœliotomy do not occur with Pfassuenstiel's incision. For suture material silver wire should be abandoned; silkworm is much better. When buried it remains definitely unaltered; further, owing to its smoothness it may be easily and painlessly removed. For subcutaneous sutures and ligatures catgut only should be used. The speaker prefers iodine to Cumol catgut. He uses catgut exclusively for vaginal plastic operations. For closing skin wounds he recommends silkworm. Finally, to keep the wound completely dry Dermato vioform or phenyform shall be used. As regards vaginal asepsis he recommends repeated antiseptic douching and cleansing before operation, and before vaginal hysterectomy the uterine cavity must also be thoroughly washed out. One often finds in a uterus an accumulation of pus behind a mass of cancer. From the moment of the first incision antiseptic or, in fact, any douching must not be employed. Blood must be mopped up with dry wipes and its source controlled with catgut ligatures. Purgation and douching out of the lower bowel must be thoroughly employed before operation. G.

Indication, Technique and Results of Operations for Enlarging the Pelvis.—During the introduction of this subject at the Congress, Doderlein (*Zentralblatt für Gyn.*, 1907, No. 24) said as regards the mortality from hebosteotomy, the open method of operation seems to be followed by the same mortality as symphysiotomy. Subcutaneous hebosteotomy with four times the number of cases has less than half the mortality of the open method, and is therefore undoubtedly superior. The improvement in results is therefore not so much due to cutting the bone as to the subcutaneous manner of doing it. The cases in which the genital tract was infected before operation account for the greater part of the mortality. A special danger lies in lacerations of the vagina communicating with the wound when the genital tract is already septic, Injuries to neighbouring organs, especially the bladder, increase the danger to life. It is not certain how dangerous thrombosis of the larger vessels at the seat of operation with resulting emboli may be. It seems they are not to be feared when there are no other complications, for example, injuries to the bladder. The danger of hæmorrhage and of death from hæmorrhage requires that this operation shall be performed with every means ready to stop such hæmorrhage. Special attention must be given in cases of severe hæmorrhage to the corpora cavernosa clitoridis. As regards injuries to the bladder he says that the most frequent cause is perforation of the bladder wall with the hebosteotomic needle, particularly when the latter is sharp. In these cases the saw will also injure the bladder. The bladder may also be injured when there are extensive lacerations of the vagina. Injuries to the bladder are dangerous to life, and have a very evil influence on the convalescence in every case. The supporters of subcutaneous perforation method have the problem of divesting the technique of this danger. As regards lacerations of the vagina communicating with the wound, their occurrence is especially to be feared among primiparæ with forced delivery. To prevent them spontaneous delivery must be waited for whenever possible, When the vagina is narrow a deep incision into the vagina and perineum must be made at the side opposite the hebosteotomy. The hæmatomata which more or less arise in the majority of cases are of no importance. They only suppurate when complicated with bladder injuries. In the after-treatment adhesive plaster or a pelvic binder is not necessary. As regards the infantile results three children were dead when born among fifty-five cases of the open hebosteotomy, and twelve among one hundred and seventy of the subcutaneous method. The most frequent causes of death are cerebral injuries, such as intracranial hæmorrhages usually associated with forceps deliveries; less frequently with version and extraction. The speaker advised 6.75 cm. as the lowest measurement at which hebosteotomy may be performed. G.

MEDICAL NEWS IN BRIEF.

An Educational Health and Food Campaign.

The Lord Mayor presided recently at the London Mansion House over a largely attended meeting convened by the Bread and Food Reform League for the purpose of inaugurating an educational health and food campaign.

The Bread and Food Reform League, an educational and purely uncommercial and non-political association, is organised to direct attention to the great importance of the food question and promote the healthy nutrition of the people, and in the proposed campaign it purposes, in connection with representatives of other societies, to disseminate information which will tend to promote health and diminish many of the diseases produced by ignorance of dietetic laws. Without advocating any special system of diet, it is desired to show the nutritive and economic value of much-neglected staple foods, the more general adoption of which would benefit the health of all classes of society and lessen suffering among those of limited means. As ignorance about food tends directly and indirectly to produce infantile mortality and physical deterioration, the council of the league decided to organize the campaign, which will consist of a series of conferences, lectures, and cookery demonstrations with distribution of literature and foods. These will be held in poor districts with the co-operation of public health and other local societies, clergy, and medical men. The King has already expressed his sympathy with the objects of the League.

After the Lord Mayor had opened the proceedings, Miss Yates outlined the objects of the proposed campaign.

Sir James Crichton-Brown moved the following resolution:—"That an educational health and food campaign be held to stimulate societies and individuals interested in the welfare of the people, to make systematic co-ordinated efforts to remove this ignorance, strengthen local health committees, and influence public opinion, so that health visitors may be established to work in conjunction with medical officers of health in spreading plain practical information among the people." He said that he was not present to advocate any special system of diet, and he particularly repudiated any vegetarian tendencies, for he had no doubt that animal food as an element in the diet of the people had largely contributed to the vigour, energy, and success of our race. By establishing conferences, holding meetings, and distributing literature, it would, it was hoped, arouse general interest in food questions and hasten the day when dietetics would be regarded as an important part of the school curriculum, and when instruction in cookery would be thorough and practical. By bringing pressure to bear on the Legislature the League would, it was hoped, promote measures calculated to check the adulteration and sophistication of food at present rampant, and with reference to certain articles to establish a standard of value. so that doctored or deteriorated stuff might no longer be palmed off on the public. Sir James spoke of the necessity of educating mothers in the feeding of infants, and of the necessity for a pure milk diet, and then dwelt upon the question of the feeding of children, particularly in its relation to education. With regard to those who could feed as they would, he said that they would do well to revert to a greater simplicity of treatment than was now customary.

Dr. Heron seconded the motion, which was supported by Dr. J. F. J. Sykes, Professor W. R. Smith, Dr. David Walsh, Mr. Pearce Gould, and Dr. A. W. Mayo Robson, who dealt with various aspects of the question.

Freedom of the City conferred on Lord Lister.

More than a century ago the Corporation of London presented the Freedom of the City to Dr. Jenner in recognition of his work in the prevention of smallpox. On June 28th, in conferring the same honour on Lord Lister, the Corporation showed appreciation of another great name whose work marks an epoch in the history of medicine. The ceremony took place in the Council Chamber at the Guildhall, where, besides the Lord Mayor and Aldermen and members of the Common Council, several representatives of Lord Lister's profession were present. These latter included the President of the Royal College of Physicians, the President of the Royal College of Surgeons, Sir Henry Roscoe and Dr. Charles Martin (representing the Lister Institute of Preventive Medicine), Sir Norman Lockyer, Sir Victor Horsley, Professor Howard Marsh, Dr. L. W. Darra Mair (representing the Chief Medical Officer of the Local Government Board, who was unavoidably prevented from attending), and members of the medical staffs of several of the London hospitals.

After the City Chamberlain's Clerk had read the Declaration of Compurgators, Alderman Guthrie and Alderman Hanson, on behalf of the Merchant Taylor's Company, presented Lord Lister for the Freedom.

Sir Joseph Dimsdale, the City Chamberlain, then, delivered an address.

The City Chamberlain offered the new Freeman the right hand of fellowship, and presented him with the certificate of freedom in a gold casket amid the applause of the assembly. The casket, which has been designed and manufactured by the Goldsmiths' and Silversmiths' Company, is supported by four scroll feet in the interspaces of which are emblems relating to science and learning. The box itself bears the arms of the recipient and views of London in enamel, and is also decorated with emblems relating to Lord Lister's distinguished career. It bears the following inscription : "Presented by the Corporation of the City of London with the, Freedom of the City to the Right Hon. Lord Lister O.M., M.D., F.R.S., D.C.L., &c., in recognition of his eminence as a surgeon, and of the invaluable services rendered to humanity by his discovery of the antiseptic system of treatment in surgery. Guildhall, June 28th. 1907." The lid is surmounted by a figure representing Hygeia, and at the ends of the base are other figures, one representing the City of London offering the scroll of freedom and the other Medical Science holding out the torch of fame.

Lord Lister spoke as follows in reply : I thank you, Sir Joseph Dimsdale, from the bottom of my heart for your overpoweringly kind words. The work which it has been my great privilege to be engaged in has been its own all-sufficient reward. Perhaps I need not say that I value in the highest degree this, the greatest civic distinction in the world. If it were possible to enhance the honour you have conferred on me to-day, this has been done by the extraordinary consideration shown by you, my Lord Mayor, and your Court, for my personal convenience. Had it not been for this your extreme kindness it would have been impossible for me in my very infirm state of health to have received your gift here in this historic building.

After some customary formalities the proceedings came to an end.

The Cancer Hospital Brompton.

A conversazione was held last night in the buildings and grounds of the Cancer Hospital. The guests, among whom were a large number of the medical profession, were received by the President of the hospital, Lord Ludlow, accompanied by Lady Ludlow. Two large marquees had been erected on the lawns, and in these light refreshments were served. The grounds and buildings were suitably decorated, and the string band of the Coldstream Guards rendered an excellent musical programme. The medical and surgical staff and other officials assisted Lord Ludlow in conducting the guests through the wards and the various departments of this institution, where the facilities both for treatment and research were fully explained. The hospital was founded in 1851 by the late Dr. William Marsden, whose wife had previously died a victim to cancer. It at first contained 20 beds, but these were increased in 1883 to over 100. There are now 114 beds available, and as the hospital is quite free, "letters of recommendation" are not needed. The wards of the hospital presented a very cheerful aspect in spite of the fact that the patients were suffering from cancer. Here every form of treatment which appears to offer any possible hope of relief is given an exhaustive trial. Special beds are set apart for the treatment of cancer by remedies that are from time to time vaunted as being of use in the treatment of this terrible malady. Every case is thoroughly investigated and careful records are kept, which provide invaluable material for the study of the disease. This close association of the clinical and pathological work of the hospital is a most important factor in the investigation of cancer, for it is only by the combined study of the disease at the bedside and in the laboratory that we may expect to obtain a solution of this very difficult problem. During the last year, 817 in-patients and 17,376 out-patients were treated, and as the hospital is solely dependent on voluntary support, funds are urgently needed to meet increasing expenditure.

The Royal College of Surgeons in Ireland.— Barker Anatomical Prize for 1908.

A prize of £21 is offered for competition, and is open to any student whose name is on the anatomical class list of any school in the United Kingdom. The preparations entered must be placed in charge of the Curator on or before April 30th, 1908. The prize is offered for dissections to illustrate the muscular and ligamentous anatomy of the shoulder-joint. The preparation must be sent to the Curator of the Museum, Royal College of Surgeons, each being marked with a fictitious signature, and accompanied by a sealed envelope bearing outside the same signature, and containing within (*a*) the full name of the competitor, and (*b*) a declaration to the effect that the work of the preparation has been carried out by himself. The printed form necessary for this declaration can be obtained on application to the Curator. The dissections are to be mounted in vessels fitted with glass covers, but the covers must not be sealed down. Earthenware basins and plaster of Paris settings are not compulsory if the specimens can be equally well displayed and preserved by other means. No prize will be awarded unless sufficient merit be shown. Those competitors who enter dissections for which prizes are not awarded, but which show sufficient merit, may be refunded such amount of the cost of production as the Examiners deem fit. The costs and risks of transport must be borne by the student. The College will not be responsible for any damage the preparations may sustain ; but those of unsuccessful competitors residing at a distance will be carefully re-packed and handed to the carriers for delivery at such address as may be specified by the student.

Distribution of Prizes at the London Hospitals.

The season for annual distribution of prizes at many of the Schools of the London Hospitals has now begun. At the Westminster Hospital yesterday, the Right Hon. Alfred Lyttelton, K.C., M.P., presided ; Sir Arthur Rücker, D.Sc., LL.D., F.R.S., will present the medals and Prizes to the successful students at Guy's tomorrow at 3.15 ; whilst Professor Osler, F.R.S., will fulfil a similar function on July 11th, at 3.30 p.m. at St. Mary's. Mr. Rider Haggard took the chair at a similar gathering at St. Thomas's last week.

NOTICES TO CORRESPONDENTS, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessary for publication but as evidence of identity.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page £5; Half Page, £2 10s. Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Tendo.—Melanotic sarcomata are most frequently derived from pre-existing pigmented spots, such as moles, and even where the growth appears to be primary or spontaneous it may frequently be traced to some unsuspected and obscure lesion, such as a pigmented spot in the rectum or vagina. But some of the melanotic growths are in all probability primary, *i.e.*, not derived from pre-existing pigmented structures.

W. H. M. (London, W.).—We might possibly publish the communication you send if the formulæ of the preparations could be also published. If the gentleman is actuated by philanthropic motives—which we do not doubt for a moment—he will surely appreciate the argument that no medical man could take the responsibility of prescribing a remedy for a patient unless he were acquainted with its composition and the effects likely to arise from idiosyncrasy or other causes through its employment. Ingredients 1, 2 and 6 would require careful watching in certain cases. We do not think that the arrangement you suggest would meet the wants of the case, as it would tend to bring us under some suspicion of commercial interest, which we should not care to rest upon us.

F. R. V.—We regret to say that we can already answer your question, for the Prime Minister announced last week in the House of Commons that he has been advised by "the authorities best qualified to express an opinion" not to appoint a Royal Commission on Cancer. He held out hopes, however, that one might be appointed when the present research students have elucidated a larger number of facts for consideration. See also our editorial columns this week.

D. O. S.—The name of the work you want is probably "Anatomia Urinæ Galeno-Spagyrica," by Henricus Martinius Dantiscanus, D.M. It was published in Frankfort in 1658, but we are not sure if that is the first edition. It is not very easily picked up, but there are a fair number of copies about.

Meetings of the Societies, Lectures, &c.

Wednesday, July 3rd.

Obstetrical Society of London (20 Hanover Square, W.).—8 p.m: Specimens will be shown by Dr. Eden, Miss Aldrich-Blake, Dr. Lewers, Mrs. Boyd, M.D., Dr. Longridge and Dr. R. D. Maxwell, and Mr. Targett. Short Communication: Dr. F. E. Taylor: Typhoid Infection of Ovarian Cysts.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. J. Pardoe: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. W. Langdon-Brown: Some Points concerning Albuminuria, Phosphaturia, and Oxaluria.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—2.30 p.m.: Skin (Dr. Meachen), Eye (Mr. Brooks), Medical Out-patient (Dr. Whipham).

Thursday, July 4th.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical). 5.15 p.m.: Lecture:—Mr. E. M. Corner: Deformities of the Foot associated with Adduction.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques:—Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson). 3 p.m.: Medical In-patient (Dr. Chappel).

Hospital for Sick Children (Great Ormond Street, W.C.)—4 p.m.: Lecture:—Dr. Still: "Bilious Attacks" in Children.

Friday, July 5th.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. A. Dawson: Clinique. (Eye).

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—9.30 a.m.: Clinique:—Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. Leslie).

Vacancies.

London County Asylum, Claybury.—Junior Assistant Medical Officer. Salary, £150 a year. Applications to H. F. Keene, Clerk of the Asylums Committee. (See advt.)

Royal City of Dublin Hospital.—Pathologist, Anæsthetist, X-Rayist and Dental Surgeon. Applications to Mr. G. Jameson Johnston, hon. sec. (See advt.)

Loughborough and District General Hospital and Dispensary.—Resident House Surgeon. Salary, £100 per annum, with furnished rooms, attendance, board and washing. Applications to Thomas J. Webb, Secretary, Loughborough.

Egypt.—Sub-Inspector of Ophthalmic Hospitals. Salary, £500 per annum, with two months' salary in lieu of travelling expenses to and from England. Applications to A. F. MacCallan, Esq., 32 Bedford Gardens, Kensington, W.

West Bromwich District Hospital.—Senior House Surgeon. Salary, £110 per annum, with board, residence and laundry. Applications to T. Foley Bache, Esq., Churchill House, West Bromwich.

St. Mary's Hospital, Paddington, W.—Curator of the Museum and Assistant Pathologist. Salary, £100 per annum. Applications to Thomas Ryan, Secretary,

Warwick County Asylum.—Assistant Medical Officer. Salary, £135 per annum, with board, apartments and laundry. Applications to Dr. Miller, Hatton, Warwick.

Royal Surrey County Hospital, Guildford.—House Surgeon. Salary £100 per annum, with board, residence and laundry. Applications to the Hon. Secretary at the Hospital.

The Ingham Infirmary and South Shields and Westoe Dispensary.—Senior House Surgeon. Salary, £100 per annum, with residence, board and washing. Applications to James R. Wheldon, Secretary, 74, King Street, South Shields.

West Suffolk General Hospital, Bury St. Edmunds.—House Surgeon. Salary, £100 per annum, with board and lodging. Applications to the Secretary.

Appointments.

St. Johnston, Thomas Reginald, M.R.C.S., L.R.C.P., M.S.A. (Assistant Medical Superintendent, Lewisham Infirmary, London), to be Government Medical Officer, Fiji.

Cheatle, G. Lenthal, C.B., F.R.C.S.Eng., Surgeon to the City of London Hospital for Diseases of the Chest, E.

Cunning, Joseph, M.B., B.S.Melb., F.R.C.S.Eng., Surgeon to In-patients at the Victoria Hospital for Children.

Dickinson, J. J., M.B.Cantab., Certifying Surgeon under the Factory and Workshop Act for the Tenbury District of the County of Worcester.

Flemming, Arthur Launcelot, L.R.C.P.Lond., M.R.C.S., Honorary Anæsthetist to the Cossham Memorial Hospital, Kingswood, Bristol.

Gibson, J. A., M.D.Edin., Medical Officer for the Rural District of the Isle of Wight.

Hertz, A. F., M.B., B.Ch.Oxon., Physician to the Electrical Department at Guy's Hospital.

Jordan, A. C., M.D., B.C.Lond., Medical Radiographer at Guy's Hospital.

Lewis, Thomas, M.B., B.S.Lond., M.R.C.P., Physician to Out-patients at the City of London Hospital for Diseases of the Chest, E.

Morton, C. J., M.D., C.M.Edin., Surgical Radiographer at Guy's Hospital.

Russell, Alfred Ernest, M.D.Lond., M.R.C.P., Physician to Out-patients at St. Thomas's Hospital, London.

Smith, Robert Shingleton, M.D., B.Sc., F.R.C.P.Lond., M.R.C.S., Honorary Consulting Physician to the Cossham Memorial Hospital, Kingswood, Bristol.

Thomas, Edmund J. Fairfield, L.R.C.P. Lond., M.R.C.S., L.S.A., House Physician at the Cardiff Infirmary.

Birth.

Moore.—On June 22nd, at Monage, Dartrey, co. Monaghan, the wife of Dr. Arthur Moore, of a daughter.

Marriages.

Best—Crichton-Stuart.—On June 25th, at the Church of King Charles the Martyr, Tunbridge Wells, William Harris Best, L.R.C.P., to Audrey, younger daughter of the late Lieut.-Colonel J. F. D. Crichton-Stuart.

Dickins—Taunton.—On June 26th, at St. Nicholas, Worcester, Sidney John Oldacres Dickins, M.D., of Cowfold, Sussex, to Cicely Margaret, elder daughter of William Whitchurch Taunton, B.Sc., M.R.C.P., of Worcester.

Matthew—Young.—On June 26th, at Cheadle Hulme, Cheshire, Frederick Crichton Matthew, M.D., F.R.C.S., of St. Ives, Cornwall, son of the late James Matthew, Corstorphine, N.B., to Janie Marian, elder daughter of the Rev. William Young, B.A., of Bramhall.

Trist—Owen.—On June 26th, at St. Luke's Parish Church, Chelsea, John Ronald Rigden Trist, M.R.C.S., L.R.C.P., of Putney, elder son of Herbert H. Trist, of Brighton, to Louisa Harriet, elder daughter of E. Annesley Owen, Esq., Barrister-at-law, of the Inner Temple.

Deaths.

Bentley.—On June 20th, on board the s.s. Pegu, Lily wife of Arthur J. M. Bentley, M.D., and elder daughter of the late William Butler, Esq., of Templemore, Ireland.

Rawnsley.—On June 26th, at The Hall, Mildenhall, Elsie, wife of Major G. T. Rawnsley, R.A.M.C.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXV. WEDNESDAY, JULY 10, 1907. No. 2

NOTES AND COMMENTS.

Sir James Barr at Douglas.

AT the Annual Congress of the Royal Institute of Public Health, held at Douglas, Isle of Man, last week, Sir James Barr, who was President of the Section of Preventive Medicine, was, evidently in gay humour for he delivered a breezy address which has received more extensive report and more editorial comment than any address of the kind for a long time. The audience seem from the reports to have enjoyed the address immensely, for the report is freely punctuated with "laughter" and "applause," but the newspaper critics have for the most part been puzzled whether to take it seriously or not. The Liberal papers are indignant with Sir James for dragging their *bete-noir*, conscription, into a scientific address, and Conservative ones hope that he did not really mean anything so socialistic as a special tax on the already overburdened millionaire. One Yorkshire daily finds in the address "at least a suggestion of Rabelais," and a London evening paper thinks it "will not be far wrong," if it attributes "to pure humour" such suggestions as that physicians should be called upon to pay the funeral expenses of their patients, or that newspaper editors should be placed in the forefront of the battle in order that the nation may be rid of them. In fact to the general mind Sir James Barr's address has been most disconcerting, and everybody is asking his neighbour quite what he means. We should be sorry to take upon ourselves the *rôle* of interpreter, but it really seems as if Sir James regarded the meeting of the Congress as a little holiday, and wished to enjoy himself there. He therefore talked on all the subjects on which he had formed opinions, politics, sociology, medicine, and his friends the surgeons who made so much money, and incidentally a little public health was brought in.

Dragooning *versus* Peaceful Persuasion.

SIR JAMES BARR seems to have a particular aversion for what he calls the "Exeter Hall type of Christian, imbued with a sickly sentimentality," and the usually popular figure of John Bull. "This big, fat, plethoric, pot-bellied man is never ready for a fight of any kind," whereas, according to Sir James the ideal of manhood would seem to be a muscular Christian—not a pigmy—who is always ready to fight anyone in any place. But his great admiration seems to be reserved for German habits and the German Emperor, although, by way of letting us share in Teutonic advantages, he would have us shut out the alien. Everything English seemed to be wrong, and everything German, except the foreign alien who comes over here, about as good as possible. Well, it is a curious but happy paradox that the Britisher, with his numerous faults and with his tantalising inconsistencies and incongruities, is always a good bit ahead of the German with his military habit of obedience and his splendid organisation, so that it is possible that the physique, the health, and the spirit of the race are not so bad after all. And it would be a vast pity if opposition to public health measures were to arise by reason of English people imagining their proper liberties were to be infringed. The difference in mental habit between the Briton and the German is sufficiently shown by the course of the vaccination controversy. and public health reformers will do well to take that sad but instructive lesson to heart. It has been proved a hundred times in the past that the free-born Briton will be dictated to by no prince, priest, or governor, and in the twentieth century he is still stupid enough not to let even a doctor do what is good for him.

Infant Culture.

THERE are many signs that the teachings of what may be called the "new hygiene" are beginning to reach the lives and habits of people. True, the progress is slow, and knowledge filters rather than pours into the domestic circle; but in London already there are two schemes on foot for the prevention of infant mortality, which are both on sound lines. One of these is a school for mothers, which Dr. Sykes, Medical Officer of Health for St. Pancras, has started, and which has already achieved a certain success. No less than forty pupils are in attendance, and instruction in the proper management of the infants is bound to have a profound effect on the future health and physique of the little ones. The other movement is the establishment at St. Marylebone General Dispensary of "infant consultations" on the lines of those founded in Paris by the late Dr. Budin. Last week a meeting was held, with Lord Robert Cecil in the chair, to receive the annual report, which showed that 90 babies had been under treatment during the year, and that the benefit had been great. When our hospitals are put on right lines as consultative institutions for cases in which the general practitioner wants help, and the present overcrowded casualty departments are eased of their trivial routine work, a far more useful and noble function will lie before them, namely, that of aiding in the prevention of sickness and in the education of the poor by such means as infant consultations and the giving of hygienic advice instead of the present playful habit of doling out bottles of medicine.

A Missing Link. IT is announced that an expedition organised and equipped by the Royal Prussian Academy of Science and the Dutch Government has arrived in Java to search for the "missing link," which Professor Dubois claimed to have found there some twenty years ago. It is strange what a fascination phrases have for people. The "missing link" to the popular mind remains to be found before the Darwinian theory can be authenticated, and it is probable that it will cost as much trouble to teach them that there is no "link" missing between man and ape as that there are no lost tribes to be found or no sea-serpent to be harpooned. It is quite possible that in Java there may be some remains of pre-historic man, indeed it is said that some skulls like the Neanderthal one have been found there; but Dr. Moskowski, who leads the expedition, and his followers have as much chance of finding the "missing link" as of discovering the Golden Fleece or the Holy Grail.

Medical Referees and the Workmen's Compensation Act. THE new Workmen's Compensation Act which came into force with the beginning of this month, it is generally acknowledged, is a legal patchwork which is likely to give rise to as much difficulty in its interpretation as its predecessor. It is certain that the Government missed a great chance of simplifying its administration in not accepting the Labour amendment to the effect that in any case of dispute as to the medical aspect of the case the question should be settled by a Government referee without any legal proceedings being necessary. It is hardly to be supposed that County Court judges will take more kindly to the assistance of medical assessors than they have done in the past, and the same process in disputed claims is likely to go on with the same result, namely, that the working man whose case presents obscure medical points and the malingerer who is shamming "internal injury" will both be in the same box, and both will have an equal chance of a verdict. Nearly the whole of the liability for payment now consists in the nature and extent of the injury, and not one case in a hundred need ever come into court if a salaried Government referee were to be able to give an authoritative and binding decision on the facts, without the intervention of any legal process.

LEADING ARTICLES.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

THE Bill for the incorporation of the King Edward's Hospital Fund for London having passed its third reading, it may be well to place on record a final protest against certain principles which have now been formally approved by Parliament. The modification of the clause whereby absolute control over the revenues and administration of the Fund were transferred from the President to the Council was, in our opinion, most desirable. So, also, was the change of the conditions of the presidency, which it was proposed to grant in perpetuity to the Prince of Wales during the pleasure of the King, and afterwards to succeeding presidents also appointed to office by the Sovereign. These views we have long held, and have urged, as loyal subjects anxious to safeguard the best and truest interests of the Royal Family in their public relations. With profound regret we note the failure of Dr. V. H. Rutherford, the Member for the Brentford Division of Middlesex, to secure the constitution of the Council of the Fund on representative lines. The present Council is small and autocratic, and is inevitably exposed to the risk that its administration will drift into the hands of one or two active members, who will be absolutely independent of public opinion and careless of criticism. Under these circumstances there is an ever present danger that injustice will be sooner or later done in the dispensation of grants, and there will be no appeal against a body which is absolutely irresponsible. It seems almost inconceivable that a Liberal Government, to whom representative control is as the breath of its nostrils, could permit so retrograde a step to be taken in the case of a great public trust dispensing vast sums of money. As a matter of elementary fairness and wisdom the representation, both of the medical charities and of the medical profession beyond one or two of its leading corporations, would have gone far, toward securing the permanent confidence of the community. Under the present constitution there can be no guarantee against the constant recurrence of troubles of a more or less serious nature, and we regret that a great opportunity has been lost of showing the medical profession, by a graceful concession to its wishes in the matter of representation on the Fund, that the interests of the general practitioners would not in future be overlooked as in the past by the haphazard methods of modern philanthropic enterprise.

THE HOUSING PROBLEM IN DUBLIN.

IT is a commonplace among sanitarians and social reformers that none of the many problems with which they are faced can be completely solved until the poor are supplied with suitable houses at cheap rates. As Koch has pointed out, the overcrowded, ill-ventilated houses of the poor are the breeding-grounds of tuberculosis. With airy, bright dwellings, and with due regard to cleanliness such as comfortable housing always fosters, there is little doubt that the power of this plague would soon be undermined. It is in the dirty, crowded tenements that the filth diseases also persist, breaking bounds from time to time and making their way into the dwellings of the prosperous. Typhus, small-pox, measles, scarlatina, and typhoid would, in these countries at any rate, soon cease to be dreaded if the poor were supplied with sanitary dwellings, Intemperance, too, with its attendant vices, can hardly be combatted as long as the working man has no place other than the bar-parlour where he can sit in comfort when his work is done. In Dublin the problem is as pressing as in any city in the kingdom. The tubercular rate is high, and shows no signs of diminution, while the general death-rate is one of the highest in Europe. Typhus, a rare disease in English cities, persists in Dublin slums, and the other zymotic diseases contribute largely to the death-rate. Again, in Dublin the dwellings of the poor are of a peculiar nature. As the well-to-do population has first migrated from the north side of the river to the south, and again from the south to the suburbs, the mansions and large houses it has deserted have fallen into tenements for the poor. One, two, three, or even four families, find a refuge in the room which was formerly a drawing-room or dining-room of fashion. Sanitary conveniences are insufficient or absent, and there is no attempt at cleanliness. The Dublin Corporation, which has the duty of seeing that yards, halls, and staircases are kept in proper condition, pays little attention, and as the recent report of the Local Government Board shows, the condition of the tenement houses is a disgrace to a civilised community. Certain steps have been taken, however, to substitute new dwellings of a proper nature for the old rookeries. The Dublin Corporation has spent, according to Sir Charles Cameron, £345,000 in providing dwellings for the working classes. Even at best this can hardly be regarded as more than an experiment, and it must be remembered that municipal enterprise in Dublin often entails expense without proportionate returns. As Sir Lambert Ormsby pointed out the other day, the Corporation paid £33,000 for the Bride's Alley area before a brick was laid, whereas an area similar in extent was purchased by a private company for £2,000. Much serious work has, also, been done in Dublin by various companies and trusts—the Dublin Artisans' Dwelling Company, the Iveagh and Guinness Trusts, and others—a total of 4,665 dwellings having been erected by them. So far, however, the blocks of buildings put up have been altogether in central areas, replacing the more insanitary of the older dwellings. This system has many drawbacks. In the first place it is expensive, in that a highly valued property has to be bought, for many of the old rookeries are extraordinarily remunerative to their owners. Again, it dislodges a large population, which, at any rate for the time, has to seek refuge in surrounding neighbourhoods already overcrowded, and even when the building is complete it houses a smaller number of persons than had previously inhabited the old area. It is a true charge, therefore, that each block of new buildings, while it provides excellent accommodation for a limited number of persons, actually aggravates the condition in the other areas of the city. In future undertakings it will be well to attempt the alternative of building in the country within reach of the city. Sites will be cheaper and surroundings more healthy; while the process of building can take place without the dislodgment of large numbers of people. Fortunately, Dublin is well situated for such an enterprise. It is compact, surrounded by open country, and furnished with an excellent tram system. The problem, as a whole, must be faced, and that shortly. Only the fringe of the subject has yet been touched, and the eulogiums showered on the Dublin Corporation by certain of the Dublin speakers at the recent meeting of the Royal Sanitary Institute seem to us sadly premature. With a death-rate the highest in the kingdom, to boast of sanitary progress is either disingenuous or ridiculous.

CURRENT TOPICS.

Motor Cars and Dust.

MOTOR dust has naturally come in for a good deal of attention at the Isle of Man Public Health Congress. Although of modern origin this nuisance has pervaded the length and breadth of the land with a thoroughness that cannot be gainsaid. Motor dust is not always, as some people seem to imagine, a distribution of deadly disease. Good clean country dust may not cause much damage to mankind beyond making his eyes smart and his nostrils water for a time. In a town, however, a cloud of dust may be charged with harmful microbes of all sorts and conditions of disease, which are not dissipated harmlessly into surrounding fields and hedgrows, as in the country, but find their way into our living rooms, our kitchen, our larders, our dairies, and, in a word, into every nook and corner of every habitation made with hands. The ousting of the horse by motors means the lessening of the pollution of road dust with horse manure. That is one compensation against the drawbacks of motor traffic. Others come indirectly through the necessity of bettering and perfecting our methods of road paving, and above all, of road cleansing. The President, Dr. Hele-Shaw, foreshadowed the time when the wheel of to-day would be superseded, and when it would be possible to carry heavy loads at fair speed without damage to the roadway. It is quite time that the creative genius of the nation rose to checkmate the long-standing nuisance of the motor dust.

Annual Election to the Council of the Royal College of Surgeons, England.

THE annual election to the Council of the Royal College of Surgeons, England, took place on the 4th inst., and resulted in the return of Messrs. Charters Symonds, Bruce Clarke, Mansell Moullin, and Eve. The poll was the heaviest on record, upwards of 800 fellows voting out of 1166. In the complete absence of any political questions to disturb the feelings of the electorate, each Fellow probably voted for the candidate for whom he entertained some friendly feeling. Thus on these grounds, no doubt, it has come about that the representatives of the largest medical schools have attained their ambition—namely Guy's, St. Bartholomew's, and the London. In one respect the result of the election has been somewhat remarkable, namely, in the non-success of Mr. Herbert W. Page. Mr. Page was seeking re-election, and the usual course of events, under such circumstances, is for the retiring councillor to be again returned. Such, however, was not the case so far as Mr. Page was concerned, although both his colleagues who were seeking re-election, namely, Mr. Mansell-Moullin and Mr. F. S. Eve, were successful. St. Mary's Medical School, to which Mr. Page belongs, cannot, of course, compete in size with the other large schools named, and this may have had something to do with the failure of their representative to secure re-election. The return at the head of the poll of Mr. Charters Symonds, who was competing for the first time, plainly shows the weight and influence of the alumni of a large and important school like that of Guy's. So far as Mr. Bruce-Clarke is concerned we desire to offer our congratulations upon the success which has attended his second effort to enter the Council.

"Siamese Twins."

IN the "Clinical Records" in THE MEDICAL PRESS AND CIRCULAR this week, we record an unusual case of conjoined twins which occurred in the practice of Dr. Keane Healy. The monster, which was born dead, possessed two heads, two necks, four arms, a double pelvis, four legs, but only one thorax and abdomen. This particular variety is extremely rare. Conjoined twins were divided by Dr. Playfair, who collected thirty-one cases, into four classes, namely, those having nearly separate bodies united in front to a varying extent by thorax or abdomen; those having two nearly separate bodies united back to back by the sacrum and lower part of the spinal column; dicephalous monsters, the bodies being single below, but the heads separate; and, finally, those with bodies separate below, but whose heads were fused, or partly united. Dr. Keane Healy's case, therefore, does not fall under any of these divisions for it had a complete double set of limbs, two heads and necks, but only one thorax and abdomen. To meet with such a creature is hardly, perhaps, a matter of congratulation, but it is certainly an event in a medical man's routine of existence.

Lists of Consultants and Specialists.

SOME few years ago an enterprising firm of London chemists published a list of consultants and specialists. Their publication was speedily scotched by the British Medical Association, who wrote individually to every medical man whose name was included therein. The official letter thus issued fell with the suddenness of a thunderbolt upon the gentlemen in question, whose names had been thus pilloried without their authorisation. We presume the British Medical Association will take similar notice of a publication of a similar nature recently issued by the Scientific Press, wherein a so-called classified directory of medical consultants and specialists is appended to a list of "Medical Homes for Private Patients." The proceeding is certainly not in accordance with the ordinary code of professional ethics, and the men whose names are thus paraded in the public gaze deserve our sympathy. The book is sold at sixpence. It is edited by a layman, a fact which perhaps accounts for some extraordinary omissions from the list. This light-hearted compiler, for instance, selects seven names from Scotland and five from Ireland. The most distinguished men in both countries are conspicuous by their absence. We trust that the gentlemen whose names appear and the association committee will enter their protest against this unwarrantable trespass upon the decencies of private and professional life.

An Echo of the Alcohol Manifesto.

THE echoes of the alcohol manifesto published some months ago by a contemporary in the shape of a letter signed by a number of leading medical men have already resounded far and near, and seem likely to be continued into a distant future with recurrent multiplication. The medical profession has been extensively billed with reprints by a trade journal. Some time ago a number of persons interested in temperance matters signed a memorial to the British Medical Association urging them to make a counter declaration at their Exeter meeting against the use of alcohol as a food and a beverage. The petition was duly presented by a medical man who is one of the honorary secretaries of the Exeter Total Abstinence Society. The Council of the Association have declined to accede to the demonstration. Nor is it easy to understand why the most ardent temperance reformers should not be satisfied with the counter declaration to the manifesto published some weeks ago in the columns of the MEDICAL PRESS AND CIRCULAR. We have reason to believe that our own document received less publicity from the temperance journals than the original somewhat revolutionary manifesto.

Premature Burial.

A MEETING was held in the City recently to forward the aims of the Association for the Prevention of Premature Burial, and from the accounts of its proceedings that have appeared we should judge that the blood of the audience must have run cold. One of the speakers, Mr. George G. Greenwood, M.P., related that two members of the Association had gathered together 149 cases in which people had been buried alive, 219 in which they had narrow escapes from the same fate, and 10 in which they had actually been dissected alive! We should doubtless be accused of prejudice if we threw any suspicion of doubt on the authenticity of these records, but we cannot help wondering from what source they were compiled. Were the cases culled from ancient or modern literature? And were any historians more trustworthy than the modern reporter relied upon? The person who just escapes being buried alive is a chronic newspaper canard, or rather, we should say, a recurrent one. It is due about once every three months, and it is seldom that it fails to turn up to time. No doubt lay persons who have never seen a dead body may make mistakes about the fact of death, but we would back the ordinary undertaker, and *a fortiori* any medical man, to know the difference between any trance yet invented and *horrida mors*. But we should certainly support the contention of the Association that death certification should be more carefully carried out, and that only a certificate signed by a medical man should be acceptable as evidence of death. As we have said over and over again, the present method by which a registrar may, and does, accept the word of any midwife or similarly uninstructed party as to the death of a human being, is a scandal in a civilised country. Happily, the Lord Chancellor is himself engaged in an investigation into the matter at the moment.

A Substitute for Radium.

An unconfirmed rumour comes from Paris of the discovery of a substance possessing qualities similar to those of radium bromide. The latter-day rival of Professor and Madame Curie is a medical student of Rochefort, who has only recently attained the mature age of twenty-one years. The new substance is said to cost sixteen shillings a gram, as against £120 a gram, which is the price of the radium compounds. Should this be the case a great impetus is likely to be given to radio-active therapeutics. The costliness of radium effectually prevents any extended researches into its curative and other reactions, so far as the human body is concerned. Should this rumoured discovery be confirmed, the young Rochefort student is likely to leap into fame at, medically speaking, an extremely tender age. He has bestowed upon his product the somewhat weird and mysterious name of "Molybdopp" A detail of that kind, however, is not likely to repel workers who have been unfortunate enough to break a tube of radium at a value ranging from ten to forty pounds sterling.

A Scotch Judge on the Liabilities of Chemists.

An important judgment has been made in the Outer House by a Scotch Judge, Lord Johnson The pursuer in an action sued for £500 damages in respect of injuries sustained by his daughter, five years of age. The defender, a pharmaceutical chemist, of Dundee, was alleged to have said that butter of antimony should be rubbed on the head of the child, who was suffering from ringworm. He supplied a bottle of that substance with the result that the girl lost all her hair, while her general health was also injured. Lord Johnson concluded his judgment by saying that circumstances might impose a duty on the chemist, to give warning of any possible danger from the use of the article sold of which he, as a chemist, was or ought to be aware, but of which his customer was or might reasonably supposed to be ignorant. But assuming his duty as a ground of liability against the defender, his Lordship was satisfied that the drug might be used if properly applied, or at least that the defender took pains to ascertain whether it could be so used, and was reasonably justified in believing that it could be so used. His Lordship was further satisfied that, in the first place, the defender warned the pursuer that he had no personal knowledge of its being used for the purpose in question, and, in the second place, that he warned him that if used it must be applied carefully and sparingly and only with a camel's hair brush. On that evidence, his Lordship could not hold that the defender had been guilty of such neglect of the duty in question as should render him liable. His Lordship was, therefore, of opinion that no case was made against the defender of actionable negligence. This judgment serves to show the difficulty of ensuring any efficient dealing with unqualified medical practice in the present state of the law.

PERSONAL.

At the recent International Nursing Conference held at Paris, presided over by M. J. Mesurier, the English representatives included Mrs. Bedford Fenwick and Miss Isla Stewart.

Principal Donald MacAlister has been appointed a member of the Governing Body of the Imperial College of Science and Technology.

Dr. G. D. Pidcock took the chair at a special meeting of the medical profession of Hampstead, on July 3rd, to consider the constitution of the Hampstead General Hospital.

Dr. W. R. Jack has been appointed Assistant Physician to the Western Infirmary, Glasgow.

Dr. John M. Cowan has been appointed Professor of Medicine at Anderson's Medical College, Glasgow, and Dr. Ivy Mackenzie Lecturer on Medicine at the Western Medical School.

Surgeon-General G. J. H. Evatt, C.B., President of the Poor Law Medical Officers' Association of England and Wales, took the chair at the annual meeting of that body at the Trocadero on June 27th.

The name of Dr. Charles Creighton has been placed on the Civil List for the pension of £75, in consideration of his medical and biological researches, and of his inadequate means of support.

Lord Ludlow, who was accompanied by Lady Ludlow, received the guests at the Conversazione in the grounds of the Cancer Hospital on July 2nd.

Mr. Mayo Robson presided at a conference on Milk Contamination and Distribution at the Incorporated Institute of Hygiene on July 1st.

Dr. Lehmann has been appointed by the Chinese Government, for two years, Chief Medical Sanitary Officer of Mukden.

The Council of the University of Sheffield have appointed Mr. Percival E. Barber, B.A.Cantab., M.R.C.S., L.R.C.P., Surgeon to the Jessop Hospital for Women, to the post of Lecturer in Midwifery and Diseases of Women, in succession to Dr. J. W. Martin.

Professor Alexander Macphail, of St. Mungo's College, Glasgow, has been appointed Lecturer on Anatomy in the Charing Cross Hospital Medical School of the University of London.

The Liverpool Chamber of Commerce, in connection with the meeting of the Associated Chambers of Commerce in that city in September, has agreed to contribute £250 to the Liverpool School of Tropical Medicine to establish in Liverpool an exhibition of colonial products under the direction of Lord Mountmorres. The Cotton Exchange has placed at the disposal of the chamber the old Cotton Exchange for the purpose.

A Clinical Lecture

ON

SOME OBSERVATIONS ON INTRA-ABDOMINAL ADHESIONS, WITH ILLUSTRATIVE CASES.

By E. PERCY PATON, M.S., F.R.C.S.,

Surgeon in charge of Out-Patients to Westminster Hospital.

The abdomen is now so often opened for various reasons that the condition of the peritoneum during life can be much more frequently noted than used to be the case, hence the known common occurrence of intra-abdominal adhesions in cases in which they were not previously expected, but in which they have proved to be the only, or at any rate, the main lesion, has led to their being looked upon, and with good reason, as the real cause of certain abdominal troubles. No doubt in many cases adhesions are of no importance, and do not in any way affect the health or comfort of their possessor; but in other persons, and under other cicumstances, this is not so, and they may cause symptoms which are merely of the nature of some occasional discomfort, or are much more severe, even amounting, as is well known, to the most acute intestinal obstruction.

How frequently adhesions may be expected to be found in the abdomen I know of no statistics to show, nor do I think that it is likely that any such exist; but that they must be very common is clear from the frequency with which they are seen *post-mortem*, and the way in which one comes across them when there is no reason to expect them in the course of operations.

Any form of irritation of the peritoneal surfaces may cause adhesion between one surface of peritoneum and another. This irritation may be mechanical, chemical, or due to a micro-organic infection. The first two causes mentioned will only occur as the result of injury or operation or in consequence of the rupture of some hollow viscus, while in other cases infection must be the reason for their formation. The nature of the infection may be acute or chronic; but in the acutest forms adhesions are sometimes conspicuous by their absence, as, for instance, in the following case:—

Case 1.—A girl æt. about 20, was attacked, almost suddenly, with acute pain in the abdomen, sickness and diarrhœa; she had been practically well to the day before this illness, when she had felt a little seedy, she had not been ill in any way previous to this; she became very rapidly collapsed, and I saw her about twelve hours after the onset; she was then suffering from acute general peritonitis, the cause from which was obscure. I opened her abdomen in several places in order to examine the condition of the stomach, appendix, and pelvic organs; there were universal signs of peritonitis, but no fluid and no adhesions, the surface of the membrane having a generally greasy feel; no cause could be found at the operation for the trouble; this had to be terminated in consequence of her collapsed condition, but after death it was discovered that she had a new growth in the sigmoid which had not previously given her any trouble, and no doubt the infection of the peritoneum had occurred here, though there was no perforation. The peculiar greasy feeling of peritoneum above described is commonly found, I think, in those cases of very virulent peritonitis, such as are seen not very uncommonly in connection with appendicitis, and as a rule adhesions are absent in such a condition. On the other hand, in some acute cases adhesions may be formed with very great rapidity, as I shall mention later. That micro-organisms will pass through the, to the naked eye, uninjured intestinal wall, the case just related shows well, for a culture obtained from the surface of the inflamed intestines gave a pure growth of colon bacillus.

The chief causes for the formation of intra-abdominal adhesions may be enumerated as follows:—In the upper half of the cavity gall-stones and other affections of the gall bladder, and ulcers of the stomach and duodenum, while in the lower half the appendix and in women the pelvic organs are much more frequently to blame. In addition to these causes may be mentioned any inflammatory trouble of the intestines.

That external injury may be sometimes responsible for the formation of adhesions, even when no gross lesion has occurred to the intestines, was very clearly shown by a case that had been under my care recently.

Case 2.—The patient was a man, æt. about 40, who was admitted into hospital with acute intestinal obstruction; no history of injury could be obtained from him before the operation, at which it was found that a large packet of small intestines were so adherent to one another that the kinking so caused had obstructed the gut. With a good deal of difficulty these adhesions were separated and the raw surfaces of the peritoneum carefully stitched over with normal membrane. The man made a good recovery from the obstruction, though he was attacked with bronchitis a week after and was ill for a long time with this. A subsequent further investigation of his history revealed the fact that six months before his present illness he had received a blow on the abdomen from the pole of a van, which was severe enough to lay him up for about three weeks, and this, I think, was undoubtedly the cause of the adhesions. Not improbably even in such a case the injury permits some passage of the micro-organisms through the gut wall, and it is at any rate in part to the irritation to which these give rise that the adhesions are really due.

The *form* which adhesions take varies very much in different cases; sometimes they are broad, extensive and firm, at others they are long, thin and cord- or even thread-like; it is the former kind that interfere most with the motility of the abdominal organs, while the latter are not infrequently responsible for the kinking and snaring of the gut which leads to obstruction, and may also, especially about the stomach, cause a good deal of pain.

The *rapidity* with which adhesions form is of considerable importance to the surgeon, as it is not infrequently the case that upon this he has to rely for the success of various abdominal operations, and for the prevention of the fouling of the general peritoneal cavity in sudden inflammatory attacks of the organs contained within it.

The following case will give some idea of how rapid the formations of adhesions may be :—

Case 3.—A year or two back I was asked to see a lady who was suffering from perforation of a gastric ulcer. She was æt. about 50, and when I saw her was clearly desperately ill, but in view of the fact that operation was her only chance, it was therefore done. She died two or three hours after it was finished. At the operation practically no adhesions were encountered, but at the autopsy there were many adhesions matting the various viscera together and some of these were of considerable firmness and required some force to separate them.

A very important question may be asked here, namely, do adhesions when once fairly formed ever disappear ? The answer to this query is undoubtedly Yes, as the following cases, among many others that could be cited, clearly show :—

Case 4.—A salvation army officer, an intelligent man, came to see me a little time back with a view to having a radical cure of hernia done, and at the same time having his appendix removed and a ventral hernia, which had followed on the opening of an abscess which he had had in connection with his appendix some little time before in India cured. The history that he gave was as follows : He had had an ordinary attack of appendicitis, this had resulted in an abscess, which was opened and drained by a tube which at first was about six inches long and which was kept in for at least six weeks. It was clear, therefore, that at this time the appendicular region must have been quite cut off from the general peritoneum by adhesions. When I operated for the removal of the appendix there were no adhesions about the organ whatever, and only one or two very fine omental ones in the vicinity. The appendix was removed and the ventral and inguinal hernias were all dealt with at the one operation.

Case 5.—Another case, that of a lad, æt. 18, is almost exactly similar, but in his case the wound had been packed with gauze at the operation, the appendix not being removed at the same time on account of the extensive nature of the adhesions, but when I removed the organ about a year later for recurrent pain in this region there was scarcely a vestige of an adhesion to be found.

A third example will suffice to demonstrate this point, which must be a matter of common knowledge to all who have frequent opportunity of watching surgical abdominal cases.

Case 6.—I was asked to see a child, æt. 11, who had been ill some weeks with an obscure abdominal illness which was now thought to be appendicitis. In this view I concurred and advised an operation. This was done, and very extensive adhesions were found about the appendicular region and some pus, and also an opening into the cæcum. It appeared that an abscess had formed and was discharging itself into the gut. The immediate result was, of course, a fæcal fistula, but the child's general condition was much relieved,. About six months later, as the fistula continued to discharge, I operated again and successfully closed the fistula by a plastic operation, but the point that I wish to note here is that as the general abdominal cavity had to be opened in the course of the operation, it was found that the adhesions noted as very extensive at the previous operation had now almost entirely disappeared.

There can be little doubt, I think, that the disappearance of adhesions is mainly brought about by the movement of the intestines upon one another due to their peristaltic action and, as I hope to show, the promotion of such movement is the best means of preventing their formation. This movement of the intestines upon one another sometimes leads to the strangest complexities when the bands of adhesion are long and cord-like, of which several examples are given in Treves's book on Intestinal Obstruction. In these cases the cord has been knotted or even double knotted round a coil of gut in a knot which might have been tied with the hands. This process seems to be aided when there is a long band formed which becomes free at one end and at this end there is a small thickened mass or knob which can slip through a loop previously made by the sliding movements of the gut.

The useful purpose peritoneal adhesions serve in innumerable cases is so well known that it is hardly necessary to do more than refer to the frequency with which they prevent the most serious and even fatal damage from occurring. For example, a patient is attacked with acute inflammation of the appendix which is speedily followed by gangrene, perforation and suppuration ; if the onset of the trouble be not absolutely sudden the intestines around adhere to one another, the omentum almost seems to crawl to the spot and speedily becomes matted to the guts and anterior abdominal wall, the result being that the seat of mischief is soon shut off from the general peritoneal cavity.

A very similar process goes on in association with trouble in Fallopian tubes, as in the following case which was under my care recently.

Case 7.—A woman, æt. about 25, gradually developed a mass in the pelvis of irregular outline, fixed, and with some inflammatory symptoms. Without going fully into the details, which are not important for our purpose at present, the diagnosis was provisionally made of tubal suppuration. At the laparotomy which I subsequently did this diagnosis was found to be the correct one, both tubes were found to be full of pus, and to be widely adherent to the intestines and the wall of the pelvis, these adhesions having successfully prevented the generalisation of an abscess which was found containing about four ounces of pus at the bottom of Douglas's pouch. The tubes were removed and the abscess emptied, the cavity being packed with gauze, the patient making an excellent recovery.

It would be easy to multiply examples of this sort showing the way in which adhesions limit inflammatory troubles or how they prevent extravasation of the contents of the hollow viscera. In very many abdominal operations it is merely a commonplace to say, that were it not for the rapidity with which we know that adhesions will form, many procedures would be impossible, as, for example, in the drainage of many cases of appendicular abscess. This often has to be carried out across the cavity of the abdomen, but can be done with almost perfect safety by packing the cavity with a little gauze, adhesions soon making a definite barrier. Again, in excisions of parts of the gut the union of the divided ends depends on the same adhesions of the peritoneal surfaces, but it is not necessary for me to multiply instances of a similar kind.

But it is true here, as in many other things, that "There is no rose without a thorn," and adhesions may be a source of very great trouble by tethering the viscera to one another in such a way as to interfere with their movements, thus causing pain and discomfort, interference with the passage of food in the proper direction, and therefore dilatation of the portion of the alimentary tract above the fixed spot. While in some cases the touble may be still more acute, urgent intestinal obstruction being the result. I may mention here a few examples of this sort.

Case 8.—A gentleman, æt. 40, had several attacks of appendicitis,. It was before the era of removal of that organ for such recurrent trouble, and the attacks at last ceased to recur after a long period of rest and invalidism; but though the inflammatory attacks did not come back he was still subject, over a long course of years, to occasional dragging and aching in the region of the cæcum which, however, was not sufficient to lay him up, this was particularly the case if the bowels were allowed to get loaded. There can be no doubt, I think, that these residual troubles, so to term them, were due to the adhesions around the old inflamed organ. The trouble, however, was never deemed sufficiently great to demand operation.

Case 9.—A few years ago a woman came under my care with the signs of a ruptured tubal pregnancy, in which there appeared to be no very acute bleeding but a gradual oozing into the peritoneal cavity. The abdomen was opened and the condition found as described above, the left tube, which was the one affected, was removed, and the pedicle tied in the usual way. The patient did well for the first two or three days, except for a little sickness which was thought to be due to the chloroform, as her general condition was excellent; but on the fourth day the vomiting became more serious and it was found impossible to get the bowels moved, though she passed some flatus. As this condition still continued the next day the abdomen was re-opened, when it was at once found that a coil of small intestine had become adherent to the pedicle of the tube which had been removed, resulting in a kinking which in the distended condition of the intestines caused an obstruction, the adhesion was easily separated, but unfortunately the condition had been recognised too late, and the woman did not recover. This case shows very plainly how a raw area of peritoneum may be the seat of the formation of a firm adhesion and points to the importance of, as far as may be, avoiding leaving such raw areas in the peritoneal cavity.

Another case of obstruction following adhesion which was the result of a blow upon the abdomen has recently been related in the earlier part of these remarks.

Apart from new growth narrowing of the pylorus most frequently occurs as the result of ulceration of the stomach with subsequent contraction of the scar; but it may also be due to the tying of the viscus to the under aspect of the liver and to other structures by adhesions. Of this trouble the following cases are examples:—

Case 10.—A man, æt. about 50, was recently under my care in Westminster Hospital. He had suffered a good deal from pain in the epigastrium, which did not seem to bear any very marked relation to food; on examination a mass could be felt in the region of the pylorus, the outline of which could not be very clearly made out. On filling the stomach with gas the viscus was found to be clearly dilated, its outline terminating at the mass above described, which was therefore plainly shown to be, as had been previously thought, at the pylorus. As the man was over fifty and had lost a good deal of flesh, the probable diagnosis was made of carcinoma; it was, however, thought wise to make an exploration in order to determine if anything could be done surgically. At the operation I found that the mass which had been felt consisted of a complicated collection of adhesions around the pylorus and pyloric end of the stomach, which was otherwise normal. These adhesions were separated, but no cause for their formation could be found and the wound was closed. The man did well, was relieved of his pain and began, while in hospital, to regain some of the weight that he had previously lost.

Case 11.—A similar case is that of a woman, æt. about forty, who had for several years been a sufferer from dyspepsia and vomiting. I was asked to see her with a view to operation by my friend and colleague Dr. Gossage. She had been in hospital some weeks, and during that time had vomited once or twice almost every day; she also had a good deal of pain at times of the character of heart-burn. There was nothing certainly abnormal to be felt in the abdomen until the stomach was distended with gas, when it was found to be very considerably dilated; it was therefore decided to do an exploratory laparotomy and, if necessary, a gastro-jejunostomy. At the operation the stomach was found to reach well below the umbilicus and there were a good many adhesions in various parts of the abdomen; the most important of these, however, were some very firm ones tying up the pylorus and the lesser curve of the stomach to the under aspect of the liver, the connection with the lesser curve being especially firm and broad. It was clear that these attachments interfered seriously with the power of the stomach to empty itself, and as it seemed doubtful whether they could be separated with success, and if they were separated whether they would not speedily reform; a posterior gastro-jejunostomy was done. For the first few days after the operation the patient was in a very critical condition, owing to the constant vomiting, a good deal of which seemed to be due to regurgitation of intestinal contents into the stomach. It was found, however, that by sitting her up in bed that efficient drainage out of the stomach was obtained, and, except for a slight attack of phlebitis in her left leg, she steadily improved having, as she said, not been so well for many years.

The adhesions in this case were almost certainly due to old gastric ulceration, though no definite evidence of this was found at the operation.

Case 12.—A third case of this sort was that of a man of about the same age or a little older. His symptoms were of a very similar nature and need not be detailed. At the operation his pylorus was found surrounded with adhesions which were clearly the cause of the reduction in the size of its lumen, as separation of the adhesions did not seem likely to give a satisfactory result, a pyloroplasty was done, which greatly relieved his troubles, but in a month or two these returned, apparently due to the recontraction of the pylorus. It was therefore thought wise to do a posterior gastro-jejunostomy, after which, though he for some time was subject to occasional attacks of vomiting of a somewhat severe nature he gradually improved, and when I last heard of him he was free from his troubles.

But adhesions may not only interfere with the lumen of the alimentary tract but also interfere with the bile passages and that of other ducts as the following case shows very well :—

Case 13.—Between eight and nine years ago a medical colleague asked me to see with him a case of jaundice. The patient was a woman between forty and fifty, and her jaundice had begun with some pain which was not, however, now at all severe, but she remained a deep yellow colour and had been so for about a year. There was nothing beyond a little tenderness to be felt in the region of the gall bladder, and as the case had gone on so long it was not thought likely that it was one of malignant disease, and the probable diagnosis was made of impacted gall stone in the common duct. At the operation a complicated series of adhesions was found tying up the pyloric end of the stomach to the duodenum, colon, gall bladder and small omentum. These adhesions were separated with difficulty and the gall ducts carefully examined but with negative result, so the abdominal wound was closed. The patient did well and gradually lost her jaundice, and when I saw her again, more than eight years after the operation, she was quite well, having never had any return of her trouble. In this case it seems that the adhesions caused a kinking of, or pressure on, the bile ducts, which was the cause of the obstruction to the passage of bile.

With regard to the *diagnosis* of adhesions, in most cases the only thing that can be done is to keep in mind the fact that this is one of the causes of the various troubles already referred to, and it is only at the operation that the matter can be cleared up, but a history of injury, or of old abdominal inflammation, or other cause for their formation make the presence of adhesions the more probable, more particularly when more gross diseases can with apparent safety be excluded.

The *treatment* may be discussed under two heads, namely, as preventive and curative.

By the *preventive* treatment I refer to the means which should be commonly used in the course of abdominal operations to prevent the viscera adhering to one another when this is not essential to the success of the operation. Reference may here be made to the experiments of Karl Vogel in connection with this matter. These observations were made upon guinea pigs. After opening the abdomen and somewhat irritating the surface of the peritoneum in such a way that in the ordinary course adhesions would have formed, various substances were used to try and prevent their formation, such as a solution of gum arabic, olive oil, paraffin, saline solution or the interposition of oil silk which was removed in the course of a day or two. None of these means, however, were found to be very successful in procuring the end in view. Experiments were made to determine if by promoting peristalsis during the after-treatment better results would be obtained; the animals were therefore fed on such food as beetroot, which was known to cause frequent movement of the bowels, and also were treated with atropine or physostigmine with the same end in view. This treatment not only promotes movement of the intestines on one another but also prevents distention, and so pressure of the intestines against one another. It was found that by this line of procedure adhesions were much less frequently and extensively produced.

From these experiments, and also from clinical experience, it may therefore be said that to prevent the formation of adhesions after abdominal operations every care should be taken at the operation to avoid anything that is likely to irritate the surface of the peritoneum, and to this end asepsis, rather than antisepsis, should be aimed at; sterile swabs or sponges and sterile saline solution being used rather than antiseptic swabs and antiseptic lotions; at the same time pains should be taken as far as may be not to rub or irritate or break the surface of the peritoneum more than is absolutely necessary, and when it is feasible to cover in raw surfaces uncovered with peritoneum by carefully suturing a layer of that membrane over such areas.

The *preventive after-treatment* is no less important than the method of doing the operation, and should be along the lines indicated by the experiments detailed above, that is to say, the bowels should not be kept confined, but should be moved at an early date unless this is especially contraindicated by the nature of the operation. As mentioned above, this serves two purposes as far as adhesions are concerned, namely, it causes movement of the intestines and so prevents two coils from lying constantly in contact with one another, and also at the same time prevents distention, and therefore pressure of the intestines and other organs against each other. Quite apart from the prevention of adhesions this line of after-treatment, which is exactly the reverse of that adopted in the early days in the management of abdominal sections, has other advantages, and it is familiar to all who have much experience of such cases how very different is the condition of a laparotomy patient before and after the first free evacuation of the bowels subsequent to the operation.

I do not think that the particular means to be used for opening the bowels is of very much moment. Personally, I generally give five grains of calomel the day after the operation and follow this with a turpentine enema containing half an ounce of the oil about five or six hours after the calomel has been given. If the enema does not have a satisfactory result it can be repeated in the course of an hour or two and a further dose of calomel given later if necessary. The administration of the calomel in one grain doses every hour till the bowels are moved has been strongly recommended by some, but I have not adopted it as it has seemed to me to cause more griping than the method described. Some prefer to give magnesium sulphate, but I have found that it is usually rather more difficult to prevent the patient bringing this up than the calomel when it is given before the anæsthetic sickness has entirely passed off or when it has only just stopped; it may, however, be given with advantage, I think, if the first dose of calomel does not act satisfactorily. I have not tried atropine or physostigmine as recommended by Vogel on the ground of his experiments.

The *curative* treatment of adhesions that have already formed is carried out on just the same lines as indicated above, after the attachments of the organs to one another have been separated; this has been exemplified by one or two of the cases recounted. Unfortunately, however, in some cases the adhesions reform in spite of every care at the operation and in the after-treatment; also in some cases the connections of the viscera to one another are so dense, and so extensive, that to divide them would be too hazardous a procedure while at the same time the likelihood of preventing their reformation, if so extensive, would be very small; under such circumstances a gastro-jejunostomy or a pyloroplasty, as was done in two of the cases that I have described, or some similar operation in different circumstances, may be found to give satisfactory results.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Seton Pringle, M.B., B.Ch. (Univ. Dub.), F.R.C.S.I., Surgeon to Mercer's Hospital, Dublin. Subject: "The Treatment of Carcinoma of the Great Intestine."*

ORIGINAL PAPERS.

THE GENERAL PRACTITIONER.

I.—His Outlook.

By J. LIONEL TAYLER, M.R.C.S., L.R.C.P. Lond.

The position of the general practitioner needs re-defining. He has gained in knowledge; to some extent in social recognition, and his responsibilities have greatly increased. Yet his status in the medical profession has hardly changed from that which it was nearly a century ago.

He has gained in Knowledge.—Writing in 1803, Thomas Percival, in the then standard work on "Medical Ethics," quotes with approval Adam Smith (*a*) to the effect that the apothecary "is the physician of the poor in all cases and of the rich when the distress or danger is not very great." This same apothecary, who had a very imperfect medical training, dispensed his own medicines, and Percival condemns the practice of a physician sending prescriptions to the druggist rather than allow the apothecary who is consulting with him to do it himself, and charge the patient for his trouble. He adds, however, that the physician should occasionally inspect the drugs that the apothecary uses, so as to see that they are satisfactory. In the whole work it is made clear that the apothecary is inferior in all respects to the physician, as at that time in the large majority of cases he undoubtedly was.

In 1849 a third edition of this work was re-issued and as it still seems to have been regarded as authoritative, and as no comment on the old passages dealing with the status of the apothecary were inserted, it may be taken that the view presented was still more or less representative of the times. Kerrison, (*b*) however writing in 1814, after quoting the same passage from Adam Smith, asserts that the surgeons now constitute "the most numerous class of general practitioners in England and Wales," while Mackenzie (*c*) writing on "Specialism in Medicine," seems to place the beginning of the tendency of consulting physicians and surgeons to specialise somewhere about 1860. Therefore, the low standard of medical efficiency exhibited by the general practitioner began to be modified somewhere about the second decade of last century, if we are to trust Kerrison. It was still a low one in 1849, but from this time a gradual improvement took place, so that the consulting medical practitioner commenced to specialise in particular branches of medicine, because presumably more specialised knowledge came to be better appreciated.

There can be little doubt that the better qualification and culture of the general medical man has caused him to rely more upon himself in all diseases that he is familiar with, but probably also to seek more freely advice for disorders that are unfamiliar. This change, be it noticed, alters the relation that has hitherto existed, for the position is no longer that of inferior and superior, but of generally experienced and specially experienced workers. His status being no longer a subordinate one, his authority in medical matters should be more recognised.

The Gain in Social Status.—It is indisputable that the medical practitioner's social position has improved. One has only to glance at the earlier and later literary writers of last century to realise this fact. Dickens, and earlier men make this evident. The Bob Sawyer type of student and practitioner; the surgeon swearing at his patients, though these are varieties that may still exist, are yet now in such marked minority as to be no longer representative of any section of the profession to which they belong. And the general public, whatever view it may take as to capacity, has recognised the greater refinement that has become evident as a result of better education in our profession.

His Responsibilities have Increased.—This point like the last is a commonly acknowledged fact. Since 1870, when the education of the poorer classes of the community became recognised as a public necessity, the medical practitioner has had more and more responsibilities in reference to school questions thrust upon him. And, before this, factory legislation has given him both an interest and an incentive to study employment liability risks, and assurance societies have accentuated the tendency.

The fact that patients are now far more ready than formerly to detect failure of skill in their medical attendants has raised the general standard of efficiency, but it has also added much to the anxiety of medical practice.

Yet his Status in the Medical Profession has not Improved.—It is a curious fact that, in spite of this obvious upward change, both in his own capacity and in the class of practice which he has had to undertake, the general practitioner is still regarded as being largely the inferior of the specialist, precisely as the old apothecary really was to the more skilfully trained physician. His representative rights are very little improved. His voice

is seldom heard in the medical journals, and he is never invited to contribute to the larger medical text books or to deliver lectures at medical training institutions. In every respect he is treated, though courteously, as a subordinate whom the principal has nothing to learn from. This attitude cannot fail in the end to lower the general practitioner in his own estimation and cause him to take less interest in his work, and it must be finally disastrous to the whole medical profession.

It is claimed by the writer of these articles that the general practitioner has a *distinctive* position of his own, which the specialist is quite unable to represent; that his position should therefore no longer be a subordinate one as heretofore. The simple difference between him and the consultant being wholly and solely one of aspect of approach to common studies. Hence, if these contentions are sound, it will be evident that a change in his professional status is advisable, corresponding with the change in the character of his work.

I hope to take up "The General Practitioner's Claim to Recognition," in my next essay.

FRACTURES OF THE SHAFT OF THE FEMUR—A DISCUSSION ON THEIR TREATMENT AND DIAGNOSIS. (a)

By SIR THOMAS MYLES, M.D. Univ. Dubl., F.R.C.S.I.

Surgeon to the Richmond Hospital.

FOR a long time past it has seemed to me that surgery, while advancing by leaps and bounds in other domains, has been singularly unprogressive in the matter of fractures, especially of fractures of the thigh. One reads every day in the journals, records of daring and brilliant operations in the abdomen thorax or cranium. Suggestions full of careful thought are made by many workers in these fields, but, so far, little progress has been made and, with a few exceptions, but little surgical thought has been bestowed on the subject I have chosen for my communication. In this particular branch of surgery the surgical mind seems to have fallen into what Swinburne calls "the slothful hebetude of the grave." We are still not merely in the early Victorian age—that era of ugliness—but it is hardly an exaggeration to say, in the days of Galen and Hippocrates. The full tide of human thought has swept past us, engulfing old landmarks in almost every direction, but here a rigid conservatism apparently offers an insurmountable obstacle to progress, and one still sees in a most up-to-date hospital, fully equipped with the costly appliances demanded by modern surgical technique, patients with broken thighs treated by practically the same methods as their predecessors have been treated for the last hundred years, or even more.

Very few appear to consider the subject worth giving more than a passing thought to, and the result is that progress has been practically nil. And yet the subject is worthy of the most careful consideration, as I hope to show very soon. One reason why it had so little consideration bestowed on it, perhaps, is that medical men themselves rarely suffer from fractures of the femur, in this respect contrasting markedly with appendicitis, enlarged prostate, and other more widely diffused ailments, the prospect of being a possible subject to each or any or all of these maladies being constantly before our mental vision, thus stimulating that imaginative faculty which is essential for novel suggestions. If medical men themselves were more frequent sufferers from these injuries they would long since have rebelled against the traditional methods of treatment, and more modern methods would soon have displaced the older ones.

Fracture of the femur is not a common accident; practically it presents itself amongst two classes of the community only—the workingmen and the sportsmen. Of course, it may happen to anyone in a railway or other accident, but, speaking broadly, it is met with most frequently amongst the classes I have mentioned. Now it may not be of any great consequence to a millionaire or a salaried official to be lame and weak in one leg, but it means a great deal to a hunting man, and still more to a workingman, whose bread depends on his muscular efficiency. The first question I have set myself to consider, therefore, is that of the prognosis in such an injury in a workingman or a hunting squire. Is a workingman as efficient after this accident as before, and can a sporting man ride, shoot, play cricket, tennis, etc., as well as he used to before he broke his femur? The answer to these questions can be supplied in part by one's individual experience, and in part by a study of museum specimens and X-ray photographs. My own experience of the result of routine treatment in these cases is not very encouraging. I have found that in nearly all cases occurring in adults there has been considerable shortening and consequent lameness, some stiffness in the knee-joint, some limitation of the movements of rotation at the hip-joint, a varying degree of muscular atrophy, pain with changes in the weather, and almost always an ugly nob of callus to be felt or seen at the seat of the united fracture. Some of these patients amongst the well-to-do found that riding became painful afterwards, probably from the pressure of a bony projection on some of the nerve trunks; none of them could run or jump as they used to do, and they all suffered for some years after from coldness and œdema of the foot on the injured side. At first I felt inclined to blame myself for these results, but further study of the subject soon taught me that they are the invariable and inevitable results of the methods of treatment usually adopted—methods sanctioned by tradition and the teaching of the schools.

A study of the museum specimens of this injury is very instructive, and calculated to modify one's previous conception of what actually takes place in these cases. We are not all pathologists, nor have we all access to museum specimens, by the study of which we may hope to educate ourselves; consequently we are not much to blame if our imaginary conception of what takes place in these injuries is found to differ very materially from the actualities presented by museum specimens. I remember once, some years ago, asking a well-known surgeon of great intelligence—now, alas! no more—if he found as great difficulties as I had in effecting even decent approximation of the broken ends in fractured femur. To my astonishment he told me that under an anæsthetic he had never any difficulty in effecting perfect end-to-end apposition in transverse fractures, and that he always got good results in such cases! I could only congratulate him on his good fortune, and envy him the mental condition which enabled him to hold such a belief. Now such a belief—absolutely foundationless—is fairly widespread. The general idea amongst such believers is that it is not difficult under complete anæsthesia to get end-to-end apposition of the fragments, that they can be held in this position by splints, weight and pulley arrangements, etc., and that a nice spindle-shaped lump of callus surrounds and holds the ends together, and that the patient's leg is just as well as ever after the fracture, if not a little better!

It is a very curious fact that amongst the many museum specimens of this injury I have examined I have never yet had the good fortune to meet one illustrating this method of union. One is either forced to believe that the museum contributors for several generations have wickedly combined to exclude such specimens from their collections or, *horribile dictu*, that such specimens do not exist. That the latter is the more probable explanation is supported by a study of X-ray photos of these injuries. Of these there are a great many now in existence, and men who have made a special study of X-ray work—such as Dr. R. Lane-Joynt and Dr. W. Haughton—tell me that they have no specimens in their collections illustrating this traditionally-accepted method of union.

(a) **Read before the Royal Academy of Medicine in Ireland (Section of Surgery) May 10th, 1907.**

As a matter of fact a study of museum specimens and of X-ray photos show certain constant factors in these cases :—

1. There is always shortening due to overlapping of the fragments.

2. The lower fragment may be in front or behind, inside or outside the upper fragment; it is never exactly where it ought to be.

3. The lower fragment is rotated either inwards or outwards; it is never in perfect alignment with the upper. It may be in approximate alignment, but it is never in the perfect alignment, and it cannot be.

4. It is absolutely impossible to decide by the unaided eye, touch, or measurements what the actual displacement of the fragment is. The mass of muscle surrounding the bone, the extravasated blood, the enveloping skin and fasciæ all combine to soften the asperities of the actual outline in the same way as a fresh fall of snow smooths out and diminishes the irregularities of contour in a landscape. It is the tell-tale X-ray which shatters one's hopes and shows us that the limb, after all our effort, is little better than a whitened sepulchre; that we are still far indeed from the realisation of our ideal. The amount of actual bony displacement that may exist, completely masked by the soft parts, is incredible to all save those who have studied this question with the aid of X-ray photos. Let anyone glance for a moment at the specimens illustrated here and he will, I think, have no difficulty in understanding why such patients complained of pain and weakness in the limb, of marked lameness, of coldness and œdema of the foot below nor is it more difficult to understand that men so afflicted can no longer ride, run, swim, or tramp across a moor, gun in hand, as they did before their accident. It is, I think, fairly obvious, therefore, that fracture of the shaft of the femur is a very grave accident indeed, and one well worthy of the most careful consideration.

Hitherto surgeons have quietly accepted the teachings of the great men of the past, that shortening of an inch or more is the inevitable outcome of such injuries, and that nothing can be done to prevent it. But surely this is an unworthy position to take up at this period of the world's history. Are we not bound to make use of all the advantages that progress in other directions has made available for us? Is the technique which has made safe the great operations in other branches of surgery not to be utilised in this particular branch of our work? Are we bound to doom a young man to lameness and inactivity for the rest of his life through lack of courage to face a comparatively novel problem? My plea is for greater boldness in dealing with these cases; that in suitable circumstances we should not deny them the advantages, added risks notwithstanding, which the improvements in modern technique have placed within our reach. Let the facts be stated frankly and plainly to our patients; let them understand clearly the risks and advantages on the one hand, the freedom from risk and disadvantages on the other, and I am convinced that the average young man will not hesitate to face the risks inevitably incidental to all operative methods.

There is one other point to which I should like to refer before leaving this part of the subject. Hitherto the loss of muscular efficiency in these cases has been attributed to the shortening due to the overlapping of the segments and possibly to some angularity at the seat of union. While not denying that these factors play a prominent part in producing the ultimate result, I am convinced that too little importance has been attached to the want of perfect alignment in the united fragments. Somehow most of us in making a mental picture of the femur consider it as roughly a straight bone, slightly convex forwards. Take a normal femur and study it carefully; it is by no means a straight bone, but a series of curves and angles. I need not attempt here to give a verbal picture the anatomy of the femur. It is to be found with more or less accuracy in every text-book of anatomy. But if we look carefully first at a normal femur and then at any of the specimens of united fracture in the museums, we cannot fail to see how large a part the inevitable lack of perfect alignment must play in producing the diminution of muscular efficiency which is so painfully apparent in these cases.

No method of treatment other than exposure by dissection holds out any hope of a perfect restoration of alignment. It is only by actually seeing the parts dove-tailed back into their original positions that we can ensure perfect alignment. Apart from this operative exposure, the most careful measurement, palpation and manipulation are in vain—even the X-ray itself fails us here. True we can rotate the lower fragments inwards or outwards, but practically we can neither precisely determine the actual position *qua* rotation of the upper fragment, nor can we adequately correct it if we wish to do so by any appliance at present at our disposal. I am quite aware that in urging the more frequent use of operative methods I am assuming a grave responsibility, and this responsibility I propose to diminish by certain limitations. In the first place, operations of the kind to be described hereafter should not be undertaken by men other than those engaged in daily operative work at the hospitals. They should not, save in very rare cases, be undertaken in private houses. They should never be performed save in healthy youths or adults.

A very perfect technique must be at the operator's disposal, and plenty of skilled assistants. The operator must have an adequate armamentarium, and his requirements in this direction should be determined by previous experiment on the cadaver. Given all these preliminary requirements, operations on fractured thighs should not be more hazardous than any of the countless operations performed in the hospitals of a great city throughout the year. It is fairly well known now, thanks to X-ray photography, that the broken ends of the fragments present great diversity in the minute details of their appearance. Sometimes the bone is broken nearly square across, with or without partial or complete detachment of angular fragments. In others the line of fracture is of varying degrees of obliquity, ranging from one to as many as five inches in length. In cases of extreme obliquity, the long axis of the bone seems to be almost bisected, so that each segment offers but little holding ground for any mechanical appliance to be embedded in. In others, again, the line of fracture is an irregular spiral; while in some the bone may be extensively comminuted. It is obvious, therefore, that it will be very difficult to make any one method of treatment equally efficient for the treatment of these divers conditions, and the surgeon who proposes to substitute operative for non-operative methods of treatment must be prepared to modify his plans as the actual conditions to be dealt with are revealed by X-ray examination, and by the preliminary exposure of the seat of fracture.

The methods I now propose to discuss are of three kinds :—

1. Simple wiring of the fragments together after exposure and drilling.

2. A modification of the ingenious apparatus suggested by Mr. Park Hill, of Denver.

3. The use of short steel screws as recommended by Mr. Arbuthnot Lane.

SUTURING WITH WIRE.

Even with the most perfect equipment the securing of a plain transverse fracture by drilling and wiring is a task of great difficulty. To get the parts rigidly into position at least four separate wire sutures must be passed, each suture entering the periphery of one segment, then emerging through the medullary canal at the seat of fracture, re-entering the medullary canal of the other segment and emerging at its periphery. If four such sutures can be passed and secured with a uniform degree of tension, an excellent result will be achieved. But practically this is impossible to accomplish. One suture must be at the side of the bone remote from the surgeon, and this suture it is practically impossible to make secure. Assuming that the ends of the fragment have been projected through the wound and duly drilled, the sutures can now be passed, with some difficult manipulation no doubt, but still the four sutures can be passed and got into position for tightening. Now comes the crux. The segments when reduced are overlapping. This overlapping has to be overcome by traction on the lower segment, but this very traction now makes the aponeuroses and muscles so tense that there is no room for one's hands to grasp and make traction on the suture most remote from the operator, and if this deepest suture is not made taut a hinge movement will be permitted by the other three—not only will a hinge movement be possible, but even a worse result may happen, namely, that the lower fragment may slide so far outwards as to be ultimately in lateral, not end-to-end, apposition. This result is due to the fact that so-called flexible wire, iron or silver, is never so flexible as silk or other common suture material. It is mechanically impossible to make wire sutures as tight as silk could be made around the four angles which each suture must traverse. Further, any slight initial relaxation that may have occurred at the operation tends to increase from day to day, partly by actual stretching of the wire itself, partly by the absorption of the bone from pressure at the drill holes. If the broken faces can be kept squarely in position these changes do not occur, but if the least lateral movement is allowed by the presence of the fourth suture the factors described at once become operative. I do not mean to say that this is a fatal objection to the method, as the defects may be neutralised by splints, but then one great advantage of the operation is lost—viz., the ability to dispense with the splints altogether and to procure immediate fixation of the fragments in their original relative positions. A consideration of these factors and practical experience have led me to abandon the simple wiring method in clean cut transverse fractures.

In oblique fractures the problem is totally different, and here the wire may be used most effectively. The method I have adopted in such cases is as follows:—An incision is made on the outside or in front, and the segments examined by both sight and touch. In these oblique fractures it is usually fairly easy to determine the previous relations of the spikes and recesses on the two fragments to each other. Once this is done it is easy to drill at least one hole in each segment in such a position as will give satisfaction afterwards. It is not advisable to drill the bone directly at right angles to its long axis. It is better to drill it obliquely, that is to say, to drill the lower fragment at a slightly higher level than the upper. This makes the wires more tense when the muscles tend to draw the lower segment upwards. This difference in level must not be too great, as then there will be a thread of wire intervening between the fragments, preventing perfect apposition. It may be advisable to drill a second, or even third, hole, but in the long oblique type one drill hole is sufficient—the upper and lower ends being simply secured by a circular lashing of wire or chromic catgut.

THE PARK HILL METHOD.

The method that I think, on the whole, promises to give the best results is that associated with the name of Mr. Park Hill. The principle underlying this method seems to me to be very sound, though in the original appliance certain mechanical deficiencies became apparent on use. These deficiencies have been largely corrected by adopting the suggestions of my friend, Dr. R. Lane-Joynt, whose mechanical aptitudes are so well known, and are placed so freely at the disposal of his professional brethren.

The apparatus which he has devised and perfected and which I am now using fairly extensively, may be described as follows:—First let me understand the fundamental principle on which the instrument is based. Everyone is familiar with the fact that a fractured tibia undergoes but slight displacement if the fibula remains unbroken. To Mr. Park Hill belongs the credit of proposing to supply to a broken femur or humerus an artificial equivalent of the fibula in the lower limb. To do this several holes are drilled in the upper and lower segments of the broken femur, at right angles to the long axis of the bone In these holes long, strong, steel screws are firmly embedded, their free ends projecting six or seven inches, or more, beyond the muscles and skin of the limb. If these free ends are now caught in a long clamp, so strong and so tightly clamped that the screw cannot move, it is obvious that the clamp becomes practically an artificial fibula to the femur, and it is equally obvious that if the fragments have first been absolutely restored to their original position, and when so restored that the clamp has then been tightened on the screws, nothing short of a great violence can disturb the bony segments. When first using this apparatus we met with certain mechanical difficulties, and all the modifications suggested and executed by Dr. Joynt have been designed to overcome these difficulties.

First you have the difficulty arising from the fact that the femur is curved slightly, and the clamp sides are striaght. In other words, assuming that four or six long screws are put from outside into the shaft of the femur, say one inch apart, and exactly equidistant from the anterior and posterior surfaces of the bone, a line connecting the external ends of these four or six screws will be a curved line, while the sides of the clamp that hold them are in a straight line. The result of tightening the clamp, therefore, will be to tend to diminish the normal forward convexity of the femur. On the other hand, if the sides of the clamp be curved, it will be necessary to equip oneself with a number of clamps to suit the varying degrees of femoral convexity and the exact seat of the injury. Again, if six screw holes have to be drilled in the shaft of the bone, to ensure that they are exactly in the proper line, each equi-distant between the anterior and posterior surfaces, it will be necessary to make an enormous incision, and to expose the bone over a very large area. These difficulties have been overcome in Dr. Joynt's modification of the apparatus by interpolating a universal joint, capable of being rigidly locked in the middle of the clamp. This device makes the instrument easier of application, and increases its efficiency enormously. Thus it is no longer necessary to make a huge incision, exposing the bone over a large area. It is now sufficient to make one incision, say two inches in length, at the seat of fracture, to enable the operator to see and feel that perfect adjustment has been accomplished. The screws, four or six in number, are inserted through small puncture wounds at some distance from the site of fracture. So long as those in each segment of bone are fairly well in line it is immaterial if those in the upper segment are not at first completely in line with those of the lower, as to be rotated in any desired direction until perfect alignment of the segments is obtained, when the clamp can be easily locked securely.

Parenthetically I may say here that the farther from the seat of fracture that the top and bottom screws are inserted the greater will be the mechanical advantages of the method in securing absolute rigidity in the fracture.

The method is not suitable for children, as the femur is too small in calibre to carry the screws well, and force applied through the screws, using them as levers, may cause longitudinal fractures of the bone; but for uncomplicated cases in adults it promises to be the easiest and safest method yet devised. Moreover, in fractures near the trochanters above, or the condyles below, it is incomparably superior to any method of wiring or the use of screws. It is in fractures near the trochanters that the most hideous results are met with from the ordinary treatment by splints, flexion of the thigh, bandages, etc. The upper segment in these cases is seriously displaced; being usually flexed, abducted and everted, the lower fragment is drawn up inside and behind it, so that when union takes place the result is something which resembles the striking end of a polo mallet. The shortening and irregularity are not the worst features, however. Owing to the abduction of the upper segment the top of the great trochanter is approximated to the pelvis, so that when union has taken place actual abduction becomes impossible owing to the top of the trochanter striking against the pelvis. Further, it is practically impossible to maintain any real extension by strapping plaster fixed above the knee only, a limitation necessitated by the flexion of the thigh required to bring about even approximate parallelism of the two segments.

Another point not to be forgotten is that in the fractures close to the trochanter minor splints applied in front exert little or no pressure on the upper segment, owing to the fact that a bandage around the thigh at the level of the perineum is really below the end of the upper fragment. Similarly the fractures near the condyles, where great distortion occurs through the rotating influence of the calf muscles, the Park Hill apparatus promises to be of great service. In this situation wiring is, from anatomical and mechanical reasons, very difficult, involving great labour and prolongled exposure of the parts, whereas even a very small lower fragment will permit of the application of two screws, one of which may be inserted into the condyle itself if necessary. The clamp and screws are left *in situ* for about four weeks, when, in a healthy patient it will be found that fairly firm union has taken place. One very striking clinical fact about the use of this method is the immediate relief from pain that the patients obtain. All muscular spasm seems to cease, good sleep is obtained, and the discharge of the natural functions is no longer an ever-recurring painful ordeal. If the technique has been perfect one dressing suffices for the entire case. When this dressing is removed a number of small crusts are found around the apertures in the skin through which the screws emerge. These latter are gently withdrawn by unscrewing. They should not, even if loose, be pulled out. In a few days' time the minute channels have healed and the patient is practically well, with a limb, save for the muscular atrophy due to inaction, as efficient and useful as before his injury. In all these operations it will be advisable to have X-ray photos taken at intervals from points 90° apart, to ensure that perfect apposition is being maintained throughout.

THE USE OF SCREWS.

This method, which owes its origin to the suggestion of our brilliant countryman, Mr. Arbuthnot Lane, is well worthy of a more extended trial than it has hitherto received. It is especially applicable to cases of oblique fractures; the greater the obliquity the better, provided that the ends of the bone are not comminuted. The method of employing screws has been given with such amplitude of detail by Mr. Arbuthnot Lane that it is not necessary for me to refer to it here. A word of warning, however, is necessary for those who are yet practically unacquainted with the method, but may wish to make a trial of it. It must not be forgotten that to ensure getting the screws exactly into correct position; the fragments must first be accurately reduced, and then firmly held in position by the special forceps designed for the purpose. This necessitates rather a free exposure of the bone and detachment of the muscles from the areas grasped by the forceps blades. If this is not done necrosis of the crushed muscle fibres may ensue and afford a nidus for infective organisms to develop in.

Again, in the small bones of women and boys the screws hardly get enough grip to make secure union. In the adult this objection does not hold, and excellent results indeed can be obtained. In fact, in a satisfactory case, the after result of the use of two well-placed screws is, to my mind, better than that obtained by any other method, but it must be acknowledged that it requires a higher degree of mechanical aptitude to use the screws properly than to employ the wire or the Park Hill apparatus. One has also to keep clearly before one's mental vision the position of the femoral vessels, that they may not be injured by the ends of the screws coming through the bone, and the length of the screws to be used must be very precisely determined before insertion. All the precautions as to riming the proximal compact layer of bone so as to allow of depression of the head of the screw, insisted on by Mr. Lane, must be carefully adopted if success is to be achieved. It will, of course, be understood, that in this method the incision to expose the fracture may be in front, or outside, as may seem most convenient, but the presence of the femoral vessels prohibits incision on the inner side of the thigh.

Recently an ingenious suggestion has been made to use an aluminium plate as an imbedded splint by fixing it with screws to the two fragments and closing the wound over the lot. I have no practical experience of the method, and therefore do not venture to offer an opinion on its merits. Further experience by its originator will doubtless in time enable us to contrast its comparative efficiency with the methods described above.

In concluding this communication I may be permitted to offer a word of advice to those who may desire to practise one or all of these methods, but as yet are without practical experience on the subject.

1. Find out as much as you possibly can as to the exact condition of the broken bone at the seat of fracture by a series of X-ray photos.
2. Think out very carefully beforehand which method is likely to give the best result.
3. Drill the bone with a Morse drill set in a brace.
4. If using the Park Hill screws see that the tap for cutting the screw thread in the bone is of exactly the same size as the screw to be inserted later, and is but little larger than the Morse drill.
5. Never try to hurry the tap, let it cut its own way in the bone.
6. When the ends of the fragments are exposed, measure their diameters and mark the screws at a point from their buried ends, exactly equal to this depth, so that they may not project through the bone, and perhaps injure the vessels.
7. If using the Park Hill method remember that the wooded faces of the clamps taken from the boiler wet will shrink as they dry, and the screws holding them in position must be tightened in an hour or so.
8. Take an X-ray photo the next day from two points 90° apart to insure that position is maintained.
9. Remember that to pass a ligature around the bones a very large and powerful needle must be used as the tough tissues about the linea aspera offer a considerable obstacle to the passage of a needle.

Lastly, practise the operation on a cadaver before trying it on the living.

CLINICAL RECORDS.

AN INTERESTING CASE OF BIRTH OF "SIAMESE TWINS."

Under the Care of J. Keane Healy, L.R.C.P.I., L.M.,

Miltown Malbay.

The following case, in general practice, will, I think, interest many of your readers:—On June 15th I was called to attend Mrs. M., who, I was informed, was sick in her third confinement for twenty-four hours, and attended by the district nurse.

On arriving, after a drive of ten miles, I examined her, and found a foot presenting through the membranes. The os was fully dilated, and on rupturing the membranes, a great quantity of water came away (at least five or six quarts). On again examining I found a second foot; but on making traction I could not bring down the birth. On making very careful examination I found two other feet protruding and, of course, came to the conclusion that it was a case of twins. I attempted to get back one of the twins, as I thought, but failed. I then got down the four legs and found I had to deal with a case of Siamese twins. I gave the patient a few whiffs of chloroform and made traction on the whole thing which (to my agreeable surprise) came away in a slop, without the slightest injury to the maternal parts. The mother has made a rapid recovery.

On examining the birth I found it had two heads, two necks, four arms, one thorax, one abdomen, one tunis, four legs, double pelvis, with anus and vagina in each, all fully developed. Mrs. M. did not expect her confinement for three weeks after this occurred. Of course they were born dead. I did what I could to get hold of the birth, but failed, as the father would not consent to give it. They were united from top of sternum to the double pelvis.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

Thoracotomy.—Mr. **Willmott Evans** operated on a case of empyema. The patient was a woman, æt. 23, married, who had been admitted into the hospital three days before the operation. A month previously she had had an attack of acute pneumonia, and two days later she was confined of a living child at full term. A day or so after this, the doctor who was attending her diagnosed a pleural effusion on the right side of the chest, and three ounces of serous fluid were withdrawn by an aspirator. Since then she had suffered much from pain in the chest and cough, and her temperature, instead of subsiding after the pneumonia, varied between 102° and 103°. An empyema was diagnosed, and she was advised to enter the hospital for operation. In the past history of the patient the only facts of importance were that she had had pneumonia when æt. 14, and several attacks of influenza. On admission, her temperature was 100°, and her pulse 108; she was very thin and looked ill. Slight dyspnœa was present, but no cyanosis. She had slight cough with a little yellowish sputum. On measurement, the right side of the chest was found to be three quarters of an inch larger in circumference than the left. The right side moved very slightly on respiration, and on percussion there was dulness as high as the fourth rib behind in he axilla and in front; from the fourth rib to the apex the note was impaired anteriorly. Over the dull area vocal fremitus was absent. On auscultation, over the greater part of the right side the breath sounds were almost wanting. In the first and second spaces anteriorly pectoriloquy was heard and there were a few moist sounds. On the left side a few rhonchi were heard, but breath sounds and vocal fremitus were normal. The heart apex beat was in the fifth space one inch external to the nipple line. The evening temperature varied from 103° to 102°, but it fell to normal each morning. The patient having been anæsthetised, was placed on her right side—that is, the affected side—and brought near the edge of the table; an exploratory syringe needle was introduced just above the eighth rib, and a small amount of pus withdrawn. An incision about an inch and a half long was made over the eighth rib in the posterior axillary line; the tissues were divided down to the bone and the periosteum stripped off the rib by means of a periosteal elevator; the bone was divided by cutting forceps, and about an inch was removed; the pleura was then incised, but many adhesions were present and it was not until some of these had been broken down by means of the finger passed upwards that the empyema was opened. About a pint of pus was evacuated. A large empyema tube was inserted, and a pad of gauze and wool applied. Mr. Evans said that in all probability this would prove to be a case of pneumococcal empyema, for the patient had had a very definite attack of pneumonia about a month previously, and, moreover, no tubercle bacilli had been found in the sputum. If this were so the prognosis would naturally be much better than if the empyema had resulted from pulmonary tuberculosis, as was so often the case. The bacteriological examination of the pus would probably clear up this point. The question of the best treatment of empyema was not so simple, he considered, as it was often thought to be. It seemed fairly certain that simple aspiration was practically never sufficient in itself. Some cases had been described in which aspiration apparently sufficed, but certainly in the great majority of cases it needed to be followed by other operative measures. Occasionally simple incision of the thoracic wall between two ribs was sufficient, but this chiefly happened in those cases where the quantity at first was not great, or where the empyema was of very recent origin, so that the lung was in no way fixed by adhesions and was able at once to resume its former size and position when the pus was withdrawn. If however, the purulent effusion was of longer duration, so that the lung had become thoroughly collapsed and contracted close to the spine, the cure of the empyema could only be effected by the falling in of the chest wall. As the chest wall falls in the ribs approximate to one another with the result that the opening made between two ribs becomes greatly narrowed, and any drainage tube placed therein is blocked. Therefore, in cases such as these, it was essential that a piece of rib should be removed. If this is done, most empyemas will get well; the chest wall falling in and the lung expanding to a certain extent. It was only in very exceptional cases that any more elaborate operation, such as Estlander's, was required, as when the lung was unable to expand in the slightest degree. With regard to the question of drainage, there was no need, in his opinion, for any great length of tube to be employed. It was sufficient if the tube reached just into the pus cavity. The approximation of the pleural surface always occurred first at the most distant part, and there was practically no tendency to pocketing of pus. One other point, he considered, deserved attention: Was it necessary or advisable to wash out the pleural cavity in cases of empyema? It was certainly not necessary, for, if the drainage was satisfactory the patient did quite well without it. Further, it was not advisable, for a certain number of instances had been recorded in which washing out the pleural cavity had been followed by immediate death. It was true that this had occurred in only a small percentage of the cases in which it had been done, but, as there was no real advantage in it, it was not worth while to run the risk. The cause of this sudden death, he thought, was probably attributable to reflex vagal inhibition of the heart, and it was not unlikely that the use of a lotion below the temperature of the body had been the real cause, for he could not see that the introduction of a non-irritating lotion at the same temperature as the pus that had been evacuated could produce any harmful results. The clinical pathologist's report on the pus in this case was as follows:—"Films show many pneumococci; cultures did not grow; probably a pure pneumococcal infection." A large amount of pus was daily poured out, but as the quantity diminished a smaller tube was employed and by the end of a week the discharge of pus had almost ceased. The temperature fell to normal on the evening of the operation day and did not again rise above 100°. The dulness rapidly diminished, and the breath sounds improved. The patient was discharged to a convalescent home twenty-five days after the operation. The wound had completely healed. The percussion note was slightly impaired at the right base behind, but elsewhere it was resonant. Vesicular breathing was heard all over both sides, though the sounds were rather weak at the right base and in the lower part of the right axilla. No adventitious sounds were present. The patient's general condition had much improved; she was gaining flesh. She was seen a month later, and was then perfectly well.

TRANSACTIONS OF SOCIETIES.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD JULY 3RD, 1907.

DR J. O. AFFLECK, President, in the Chair.

DRS. FORD ROBERTSON and DOUGLAS MCRAE showed (1) Rats showing paresis resulting from the action of Bacillus paralyticans brevis. (2) Microscopical preparations from cases of general paralysis, illustrating bacillary injection.

Dr. DAWSON TURNER showed (1) A case of rodent ulcer refractory to X-rays, but amenable to radium. (2) A case of rodent ulcer treated by zinc electrolysis.

Dr. LOGAN TURNER showed a patient successfully treated by X-rays for lupus of the larynx.

Mr. J. W. STRUTHERS showed a case of trigeminal nævus with epilepsy and paresis of the arm and leg on the opposite side to the nævus, such a grouping of symptoms had been described in other cases, and in some of these a nævoid condition of the dura had been present. In this case, however, the dura mater was shown at the time of operation to be healthy, the only abnormality present being some flattening of the convolutions. In cases of congenital trigeminal nævus it was important to give a guarded prognosis, bearing in mind the possibility of the subsequent occurrence of epilepsy or pareses.

Dr. CRANSTON LOW showed (1) A case of mixed infection—syphilitic and trilocular. The patient had various patches of lupus, and also evidences of congenital syphilis. (2) A case of erythema iris. (3) A case of bromide rash, peculiar on account of the amount of scurvy present. The patient was an epileptic and had taken bromide for many years. (4) A case of acnekeloid.

Mr. ALEXIS THOMSON read a paper on

THE MAKING OF A SHELF BELOW THE UNDULY MOBILE KIDNEY.

The principle of the operation had been introduced in America some years ago, but it had apparently not yet been adopted in Europe. He did not propose to enter into a discussion of the cause of movable kidney. If one said that it was due to pregnancy one was met by the answer that well-marked instances occurred both in multiparous women and in men. Tight-lacing, again, had been accused of its production; probably a good deal depended on the level of the constriction; if it was at the natural waist the constriction was below the kidney and would tend to keep it steady; whereas if it was higher up, at the level of the tenth rib, it might tend to displace the organ downwards. He thought that mobility of the kidney was favoured by anything, such as a tight corset, which tended daily to alter the position of the organ. Muscular strains might perhaps act in a similar way through fixation of the diaphragm during the exertion, and a consequent pushing down of the kidney. One thing which was noticeable was that the middle zone of the abdomen—from the lower end of the sternum to the tenth rib—was diminished in size in cases of dropped kidney. The arrangement of the fascia of the kidney was important in connection with displacement of the organ. The transversalis fascia split into two layers, one anterior and the other posterior, and between these the kidney lay. The two layers of fascia were firmly united in the external aspect and at the upper pole of the kidney, but on the internal aspect, and below the lower end of the organ, they were not fused, but were lost on the outer surface of the peritoneum. As a result of this arrangement the kidney lay in a sac of fascia which was closed outside and above, open internally and below. Consequently, displacement readily took place in a direction downwards and inwards. The space below the kidney, between the two layers of the transversalis fascia, was known as Gerota's space, and into this the kidney slipped, as the bowel does into a hernial sac. The new operation, which he had performed on five patients, was analogous to that for the cure of hernia. The abdomen was opened by the gridiron method; the kidney was replaced, and the two layers of the fascia below its lower pole were united by a row of sutures so as to prevent the kidney from slipping down between them. The operation had the immediate advantage over nephropexy of not being followed by the nausea, vomiting, and discomfort which stitching the kidney often produced, while the ultimate result, as regards immobility, had been very satisfactory. When there was much displacement it was best to open Gerota's space from outside the ascending colon, so as to get better access for stitching. He did not think that sudden violence could produce prolapse of the kidney into Gerota's space. As to the reason for the right kidney being so much more frequently affected than the left, the liver, of course, had been blamed for it. But in prolapse of the liver the organ rotated forward, so that it was difficult to see how it could displace the kidney downward, seeing that it only came into relation with the latter organ by its posterior part. It seemed more likely that abnormalities in the mesenteric attachments of the ascending colon played a part in the mechanism of movable kidney.

Mr. COTTERELL said that one reason why cases so often relapsed after nephropexy was that patients were allowed to get up too soon, before the recent adhesions had time to become firm. He thought that the main thing was to get the kidney into its proper position, and to keep it there for six weeks. He did not think stitching had much value; his method of operating was to plug the space between the fascia below the kidney with a large quantity of gauze, and to keep the patient in bed for a much longer time than usual after operation.

Dr. WATERSON discussed the anatomical relations of the kidney, and suggested as a possible explanation of the persistence of Gerota's space the large size of the fœtal kidney.

Mr. STILES thought the new operation promised well; he suggested combining the method of making a shelf with nephropexy.

DRS. FORD ROBERTSON and DOUGLAS MACRAE read a paper on the

TREATMENT OF CASES OF GENERAL PARALYSIS AND TABES DORSALIS WITH VACCINES AND ANTISERA.

They first referred to their previous observations on the organisms of general paralysis and tabes, and to the conclusion they had arrived at that two varieties of diphtheroid bacillus, named B. paralyticans longus and brevis, were the specific cause of the disease. This conclusion was based on the constancy with which these organisms were found in cases of general paralysis, and on the fact that animal experiment gave both symptoms and pathological appearances as characteristic of general paralysis. In preparing a vaccine sterilised cultures were used and these had been tested in eight cases of general paralysis and one of tabes dorsalis. There was usually some local reaction, and general symptoms—rise of temperature, leucocytosis, and an exacerbation of the physical and mental symptoms—which was followed by a period of more or less prolonged remission. Notes of the cases so treated were read. In the single case of tabes healed, the vaccination caused some local irritation, which was followed by lightning pains. Repetition of the vaccination, however, had resulted in considerable improvement, and had abolished the attacks of lightning pain for the time. After attaining this success with vaccines, they had tried to produce an antiserum, using sheep for the purpose. They tested the effect on the sheep by noting the bacteriolytic power of the corpuscles. At first this power was possessed by the corpuscles only to a very slight degree—0 to 4 or 6, but after repeated inoculation it rose to 70 or 80. The serum was then withdrawn from the jugular vein with antiseptic precautions, and could be kept for a considerable time. They had administered it to general paralytics by the nose, mouth, and hypodermically. Given by the mouth it was liable to produce nausea and vomiting. Hypodermically, it caused a variable amount of irritation. The general symptoms were a rise of temperature (in 17 out of 24 cases) with increase of inco-ordination, tremor, and mental confusion. Thereafter there was great amelioration of the symptoms. The antiserum had been tried in 24 general paralytics in all; in 10 out of 12 under their personal observation there had been very marked benefit, and in 3 out of 5 partially under their own care. In other cases of insanity of various types no reaction, and no change in the symptoms were produced, while in general paralysis other antisera (diphtheria antitoxin and anti-streptococcus serum) had produced no reaction. Apart from its curative or beneficial effect, therefore, they ascribed considerable diagnostic value to the serum, the febrile reaction which followed its injection being strongly in favour of the existence of general paralysis. Their conclusions were (1) that their antiserum was really diagnostic of general paralysis; (2) that in most cases it caused an improvement of the symptoms; (3) that a polyvalent serum, made from several strains of the diphtheroid organism would probably be more efficacious. (4) That the bacilli were very apt to lose their virulence, and hence it was difficult to obtain a really active serum; (5) that having prepared this anti-bacterial serum they were in hopes of obtaining an antitoxin.

Dr. **GEORGE M. ROBERTSON** read a paper on

THE PRESENCE OF A BACILLUS (MUIRHEAD'S BACILLUS) IN THE BLOOD OF PERSONS SUFFERING FROM GENERAL PARALYSIS, AND OBSERVATIONS ON THE BACILLUS PARALYTICANS.

Dr. Robertson first criticised Ford Robertson's conclusions concerning the bacillus paralyticans, on the ground that the identity of this organism was not established, and that the information given concerning it was too vague to allow of its recognition; he also alluded to the possibility of terminal infection as invalidating the significance of its discovery post-mortem, and the complexity of the flora of mucous membranes in general as a reason for being very cautious in drawing conclusions from organisms found on such sites. The observation made at Larbert had been begun with the view of confirming Robertson's researches, and the observers had confined themselves to trying to find an organism in the blood and cerebro-spinal fluid of cases of general paralysis. They had found in the blood a bacillus of the Xerosis group of diphtheroids on 15 separate occasions in 7 out of 13 cases of general paralysis. From the precautions taken he was satisfied that it was not due to any contamination. The organisms grew on agar plates, but inoculation experiments had not been successful. In order to distinguish it from the Bacillus paralyticans, and to avoid the assumption of any theory as to the part it played in the ætiology of general paralysis, they had named the organism "Muirhead's diphtheroid," after the asylum bacteriologist. They had thus failed to confirm Ford Robertson's work, never having found the bacillus paralyticans longus, and the bacillus paralyticans brevis only once, post-mortem, in association with a leptothux, circumstances which supported the idea that it was due to a terminal invasion.

Dr. **CLOUSTON** spoke of the very remarkable improvement he had noticed in the cases of general paralysis treated by the antiserum. They were all well-marked, definite examples of the disease.

Dr. **BRUCE** confirmed Dr. McRae's statement that the reaction was of diagnositic value; he doubted the pathogenic nature of Dr. George Robertson's organism, and stated that he had made many attempts to grow bacilli from the blood of general paralytics, which always failed. Dr. Robertson's success in half his cases made him (Dr. Bruce) suspect there must be some contamination.

Dr. **LAWSON** said that one difficulty in accepting the reaction as pathognomic was the absence of control experiments on normal persons; he also hoped the investigators would try to standardise their antiserum.

In his reply, Dr. **FORD ROBERTSON** said that the organism he had received from Dr. George Robertson did not give the same cultural reactions as the latter had found, and he did not think it was specific.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, July 7th 1907.

THE TREATMENT OF METRITIS.

THE treatment of the different forms of metritis is a complex problem, and frequently the practitioner hesitates, says Professor Soubeyran, by reason of the multitude of the means employed and their imperfect indications.

On the one hand the treatment should be directed against lesions of the inflamed mucous membrane (acute and chronic metritis) whose glands are hypertrophied and secrete abundantly lesions which can invade the interstitial tissues which are accompanied frequently with vascular dilatations, bleeding with the greatest facility (hæmorrhagic form).

On the other, all kinds of lesions of the os, ulcerations, polipy, rents, frequently complicated with a bad constitutional condition of the patient.

The treatment showed at first prophylatic, consisting mainly in avoiding the two great causes of genital infection: gonorrhœa and puerperal inflammation. Consequently all cases of vulvo-vaginitis and hæmorrhagic bartholinitis should be treated with care, and the husband still suffering from chronic gonorrhœa should be warned of the danger his wife is exposed to.

Puerperal infection should be treated by the ordinary means of asepsy and antisepsy at the moment of delivery or of miscarriage, and if there is retention of the debris of the placenta prompt action should be taken before the hæmorrhage has shown that the infection has already spread to the mucous membrane.

As soon as the temperature has reached 100 F., according to the principles of Pinard, an intra-uterine injection should be made.

Permanganate of potash, gr. 15,
Water one quart.

After this injection, if the temperature has fallen below 100 F., another should be given.

If the temperature exceeds 100 F. with a pulse of 120, large irrigations should be made with 10 or 12 quarts of liquid, and repeated three times daily: water, one quart; permanganate of potash, seven grains.

If, in spite of all this, the fever persisted, a curettage will be necessary, preceded by digital curage or the use of the brush.

These different means, however, should not be used until after the third day of delivery.

All the varieties of metritis require general treatment, hydrotherapy, dry rubbing, cod liver oil, arsenical or ferruginous preparations.

Constipation should be attended to as it produces congestion of the pelvis.

The patients should keep the horizontal position during the acute periods, and wear an abdominal belt, avoid fatigue, all effort and coiters.

The vaginal injections should be given very warm (F. 104 or 112), and taken in the recumbent position.

Acute Metritis.—Here all attempts at exposing the uterus should be avoided. Ice will be placed on the abdomen, or cold compresses; or, on the contrary, poultices on which are scattered a few drops of laudanum; suppositories of belladonna and opium will be prescribed, with hot vaginal injections and warm drinks. When the acute period has passed intra-uterine injections will be necessary at F. 104° every day, with a solution of permanganate of potash (seven grains to the quart). The speculum is introduced gently, the current dilator of Reverdin placed in the os. After the injection a plug of iodoform gauze is left in the vagina.

Once the gonoccocus has disappeared, injections of corrosive sublimate (five grains for a quart) should be made, and the interior of the uterus cauterized with a solution of nitrate of silver (1-50).

Chronic Metritis.—(Leucorrhœa, pain, inflammation of the cervix, &c.). In the ordinary catarrhal form, accompanied with hypersecretion of the glands extending sometimes to the cavity of the uterus, the general treatment should not be neglected, but vaginal antisepsy should be insisted upon. The essential point in the treatment is to arrive at modifying the mucous membrane by intra-uterine therapeutics.

The intra-uterine treatment is effected by three modes of procedure : intra-uterine dressings, cauterizations, curettage.

Naturally, dilatation of the cervix should precede the manœuvres when it is narrow. In the case of a woman who has had several children it is generally not necessary. The dilatation can be made by either the slow or rapid process. The former has the disadvantage of producing great pain and sometimes inflammation. For the latter the bougies of Hégar or the dilators of Sims, Clin or Réverdin, preferably the latter, for it allows dilatation of the orifice under a stream of warm water.

Irrigation of the uterus follows, after which a solution of corrosive sublimate or of nitrate of silver (1–100) is injected.

GERMANY.

Berlin, July 7th, 1907.

At the Medizinische Gesellschaft, Hr. Marmorck, a.G., introduced the subject of

The New Tuberculosis Investigation.

He had studied the early stages of the tubercle bacilli, and had made this the starting-point for his inquiries. The bacillus, in the course of two or three days, formed an exceedingly fine pedicle on the agar and also showed different tinctorial properties from the adult.

These early forms were injected into the abdominal cavities of mice after they had been washed with a solution of hydrochlorate of quinine, which served to paralyse phagocytosis and to make the animals experimented on more receptive. Treated in this manner the bacilli showed that their virulence was very slight.

In experiments on guinea-pigs, it was shown that animals springing from tuberculous mothers were more receptive to tuberculosis than those from healthy ones. In older animals the receptivity diminished.

It was by inoculation with these slightly virulent bacilli that the speaker obtained his serum.

If this attenuated virus was given to animals and tuberculin injected at the same time, in the first instance the upper part of the lungs became diseased. The administration of tuberculin also excited the toxine action, and favoured the development of cavities in the lungs. It was therefore in a position to activate weakened bacilli, which, without the simultaneous action of the tuberculin would not have been strong enough to set up tuberculosis. If the weakened bacilli were injected arterially, they did not set up tuberculosis, and when injected into the veins, at the most a slight attack of the disease.

On the other hand, tuberculosis serum injected into the veins acted much more energetically than when injected subcutaneously or intraperitoneally, and it should perhaps be injected into the vein in cases of tuberculous meningitis.

He then went on to speak of the employment of tuberculosis serum in the human subject, and formulated the requirements that were demanded in such a serum, and claimed that they were all fulfilled in his own serum. An important advantage in the employment of the serum was the fact that it could with propriety be administered by the rectum.

Hr. v. Pinquet, Vienna, had made vaccination his starting-point. After the first inoculation, immunity was induced, but it was not quite absolute. After every re-vaccination, also, a reaction arose, which, however, ran a different course as to time and was milder than the first vaccination.

If children were inoculated in the skin with tuberculin, with a vaccination lancet, there arose a small papule at the inoculation spot so soon as the children became tuberculous; this remained for about eight days and developed in twenty-four hours.

In a large number of children with tuberculosis clinically determined, this reaction took place. It only remained absent in children with miliary tuberculosis and tuberculous meningitis, and in very cachectic children.

Adults almost all reacted to this inoculation, which corresponded to the fact that the majority of hospital patients of large towns were infected with tuberculosis.

Hr. A. Neumann had treated sixteen children with surgical tuberculosis, and two adults with Marmorck's serum, and mostly by the rectum. Children received 1 to 5 ccm. daily for three weeks, adults 5 to 15 ccm. They were all severe cases. Not one showed any improvement that could not be attributed to other therapeutic measures. No injury certainly was done by the serum ; when injected into the veins also it set up no infiltration, nor did it act visibly on the general condition. He must believe, however, that it was not without effect, for the reason that during the treatment patients lost 2 lbs. to 3 lbs. in weight, which, however, they quickly recovered. Only one child increased in weight during the treatment. On the whole it appeared so harmless that patients could go about whilst it was being carried on.

Hr. Van Düren reported that no accidental complications, infiltrations, urticaria, &c., appeared when the serum was given by the rectum. The patients improved in their appetites and gained in weight. Pains ceased and secretions from fistulæ became less, and they slowly closed.

Hr. Landau and Hoffa also spoke favourably of the treatment by Marmorck's serum.

AUSTRIA.

Vienna, July 7th, 1907.

Spondylitis Infectiosa.

Schlesinger exhibited a patient to the members of the Gesellschaft with spondylitis, the result of Dengue fever, which the patient contracted in Egypt last year, but left that country about the month of October and came to Europe in the hope of recovering from the devastations of the sequelæ.

This fever commences innocently with yawning and lassitude, followed by severe pains in the joints, gradually increasing till the patient is laid prostrate in febrile agony. In a short time a remission ensues, with an exanthematous and desquamation lysis. The prognosis in most cases is good, but in the patient before the members, after many remissions, a complicated central nerve disease appeared, which from all appearance was an encephalo-myelomeningitis. After lying three weeks unconscious the patient gradually improved, though the recovery was slow, before being able to walk, when he resolved on coming to Europe seven weeks ago, so runs Becker's report who attended the patient in Cairo.

When he was received by Schlesinger in Vienna he was suffering from a painful form of kyphosis in the lumbar region, evidently developed on the journey thither. There was patella and right foot clonus on examination, but no trace of tubercle could be detected anywhere, neither could any hereditary blemish or other congenital weakness be detected. This new development seems to have been the result of the febrile poison, and therefore of an infectious character, as shown by Quinke in his case of spondylitis. This opinion has been confirmed by the improvement that had taken place since his residence in hospital. One milligramme of a tuberculin solution was injected on admission, but no reaction took place, neither locally nor constitutionally, eliminating tubercle in the diagnosis. This poisoning of the nerve system is not an isolated condition, as we meet with it in typhoid, influenza, &c., and it is reasonable in Dengue.

Atoxyl and Syphilis.

Zeissl next presented a patient that he had treated with atoxyl for syphilis as an example of others who had benefited by its administration. He would not dogmatise on the efficacy of the drug in this particular disease, but from the results he had obtained he was of opinion that the drug had some special virtue in this disease. It certainly retained the strength of a weak luetic patient where mercury and iodates would be injurious.

DIAGNOSIS OF TUBERCLE.

Pirquet presented a six months' child on whom he had performed the "Allergie" test for tubercle with a positive result. The child was received into hospital on the 12th of June suffering from an eruption on the right cheek of a doubtful character. The scab covering the sore was about five centimetres across, with a red swollen margin—the scab being yellow and black. Scattered around in the neighbourhood were a number of white tubercles, several of which were as large as beans with enlarged glands below the angles of the jaw. These tubercles also became purulent and formed scabs which, when removed, left depressions in the tissue with red efflorescent edges. Lungs, heart, and all the internal organs were healthy—no other pathological change could be discovered, unless this tubercular ulcer on the cheek, which seems to have been the primary sore causing the swelling in the regionary glands.

Now came the crucial point of determining whether this is tubercle or not. At this age tuberculin rarely acts positively, and thus tuberculoids are resorted to. Both of the arms were inoculated below the elbow, while the control was watched by a simple scratch, Around the surface (twelve millimetres), where the tuberculin was inoculated, papules presented themselves, while the simple scratch remained free.

HIRSCHSPRUNG'S DISEASE.

Schnitzler presented a child, æt. 3 years, on whom he had performed resection of the sigmoid flexure. He recommends Hirschsprung's bilateral operation for the disease as the most satisfactory.

SCOTLAND.

THE ASSAULT ON DR. CARSEWELL, GLASGOW. —THE QUESTION OF INSANITY.

DR. CARSEWELL'S assailant was tried before the High Court of Justiciary in Glasgow on July 2nd. Evidence was given as to the purchase of a revolver and cartridges by the prisoner a week before the assault was committed. When making the purchase the accused asked if the weapon would kill a man, and tested it by firing into some empty boxes. Eyewitnesses then told the story of the assault. After the accused was arrested he said he did not mean to kill the doctor, adding: "Do I look like a murderer?" He continued that he was justified in his act, and had committed it to protect himself and the public. His object was to get Dr. Carsewell brought before the public in a witness-box. Medical evidence was given concerning the extent of Dr. Carsewell's injuries, and then to the effect that the prisoner was of unsound mind His Lordship (Lord Maclaren) at this stage remarked on the exceptional course being taken by the defence. It was not attempted to prove that the prisoner did not commit the act charged, and instead of taking the usual course of trying to show that the accused is insane, the attempt was to prove that he was perfectly sane, while the prosecution was seeking to prove the opposite. The prisoner's counsel said his plea was that the accused deliberately shot at Dr. Carsewell with the purpose of bringing his case, having failed by other means, before the public. He was, however, careful not to do him serious harm, and he had pleaded not guilty under the notice that the real question at issue was as to his sanity, and his object was to prove before all else that the prisoner was perfectly sane. The view the Crown took was that the man was dangerous as a subject, and that the proper method was to treat him as a criminal lunatic. Medical testimony having been given as to the prisoner's sanity, he was then examined on his own behalf. He described how proceedings were taken without his being aware of their object, by Dr. Carsewell and Dr. Gilchrist, which resulted in his being certified as insane, and placed for some months in an asylum. He knew that while in that institution, if his wife had consented to his being liberated, he could have got out. After he did come out he raised an action against his medical attendants for wrongous certification. Failing by that means to attain his object, he tried every other legitimate means he could think of, and having failed in all these and lost all his money in the endeavour, he had taken this last course as the only one left of having this case brought before a jury of his fellow countrymen. He considered his grievance a violation of public liberty. After an absence of ten minutes the jury returned a unanimous verdict of guilty, but without intent to do serious bodily harm.

His Lordship then passed sentence of seven years penal servitude. He considered it a very serious offence. He quite believed the prisoner did not mean to kill the doctor, but he could take it from no man that he fired shots into the body of a fellow-creature not meaning to do him serious harm. He had made the sentence as light as he could.

Apart from the interest which the circumstances leading up to the assault lend to this case, the trial is remarkable as another instance of the peculiar relationship of insanity and criminal responsibility to the law. As in the New Cumnock poisoning case, the Crown tried to prove the prisoner insane, a plea which, if successful, would have barred a verdict on the facts. The evidence was to the effect that the accused suffered from delusional insanity arising from a mental deterioration quite consistent with general intelligence, and also (in the opinion of defender's witnesses) consistent with an appreciation of right and wrong, and the legal consequences of his actions. The question of insanity barring a verdict on the facts was duly laid before the jury, and it is interesting that the commonsense of the jurors very quickly arrived at the conclusion that, despite his delusions, the prisoner was responsible—in a word, the layman's position was, as we think, behind that which medicine has for long, and the law for a shorter time, tended to take up. Possibly the jury shrank from admitting the principle of an extension of mental irresponsibility, when they knew that the view of the Crown was that this would carry with it permanent incarceration in an asylum. The public mind is evidently not prepared to have everyone whom an expert declares irresponsible placed under control. From a medical point of view, however, there seems strong reason to believe that the contention of the Crown was right. The prisoner was certified as insane (and correctly certified as insane, for he failed absolutely, despite the best efforts of leading counsel, in obtaining a verdict of damages for wrongous certification), and subsequently committed a premeditated, serious crime, "to bring his case before the public." It is admitted that he suffers from mental deterioration with delusions. Who can doubt that he is a fit subject for asylum treatment? Yet by the action of the jury he is sent to penal servitude.

BELFAST.

THE CORPORATION AND THE LOCAL GOVERNMENT BOARD.—At a recent meeting of the Public Health Committee of the Corporation it was reported that a small deputation from the Committee had waited on the Local Government Board with reference to several matters recently under consideration. The deputation brought before the Board the necessity that exists for the committee obtaining fuller details of the deaths in the city, with the name and residence of the deceased, and the cause of death, so that more efficient action might be taken in the case of death from infectious disease. This information in the case of Dublin is supplied by the Registrar-General, and there seemed no reason why Belfast should not be given similar aid. The Board replied that they considered it the duty of the Registrar-General to demand from the local registrars a copy of all deaths registered by them, and the proper course was to approach the Registrar-General and obtain this information, which it was most important to have.

LETTERS TO THE EDITOR.

PROPOSED ROYAL COMMISSION ON CANCER.

To the Editor of The Medical Press and Circular.

Sir,—The excuse given by the Prime Minister for refusing to appoint a Royal Commission to enquire into the subject of cancer, was, to say the least, a very lame one—"he was advised that much remained to be done before any facts could be brought before a Royal Commission with any likelihood of their making such an enquiry fruitful for the public advantage." At any rate, this objection could not possibly apply should a Royal Commission be asked for with regard to quackery, now more rampant than ever, and producing quite as much harm as the spread of cancer itself. I trust this agitation in favour of a Royal Commission to enquire into the evils of quackery, patent medicines, &c., will not be allowed to fizzle out, but that before long public opinion will insist on such enquiry quite as necessary as that with regard to cancer.

I am, Sir, yours truly,
Alexander Duke.

London, W.

QUACKERY AND PRACTICE BY COMPANIES.

To the Editor of The Medical Press and Circular.

Sir,—Lord Hylton's Bill was read a third time and passed in the House of Lords on Wednesday last. It will now be sent down to the Commons; and those who care may believe that it will be accepted by the Lower House, and in due course find a place in the Statute Book. Since I last wrote on this subject, I have had the opportunity of seeing the full notes of the evidence given before the Lords' Committee, and I am not at all surprised to find that Dr. Heron, Chairman of the London and Counties Medical Protection Society, and Dr. Bateman, Secretary of the Medical Defence Union, express precisely the same opinion that I have twice put forward in your pages, namely, that the Bill is useless as a blow against quackery, and that at the best it could only put to temporary inconvenience the very small percentage of impostors who make use of the Companies Acts as a cloak for their nefarious games. It is amusing to note that the promotors of the Bill had to stand on the defensive, and to show that the legitimate (?) interests of unqualified quacks would not be interfered with by the proposed legislation. If, on the other hand, a Royal Commission such as I advocate, had been sitting, the case against the quacks of every denomination would have been stated, and these gentry had they dared to put in an appearance, would have been obliged to undergo cross-examination by counsel. In my letters so far I have not referred separately to the case of the dentists. It would be easy to prove before a Commission the injury to the public from quack dentistry. The quack's bait—artificial teeth at prices which would not pay for the work if the operations could be reduced to a mere mechanical routine, which is, of course, impossible—attracts mostly simple and foolish women. Virtually, they never get teeth at the prices promised. They are supplied with teeth of the most inferior make, and the remaining diseased teeth and roots are invariably left without the necessary treatment. As a result, in a vast proportion of cases, a septic condition of the mouth is kept up which is often enough seriously to affect the general health, and even to form a contributory cause towards a fatal termination of an existing malady. The quack dentist is only less harmful than the quack doctor because his scope for mischief is more limited.

I am, Sir, yours truly,
Henry Sewill.

Cavendish Square, July 4th, 1907.

IS ENGLISH LOCAL GOVERNMENT A FAILURE?

To the Editor of The Medical Press and Circular.

Sir.—In spite of the recent scandal of criminal convictions, we find that at last week's election of a new Board of Guardians for West Ham, only 15 per cent. of the burgesses recorded their votes. On previous occasions you have allowed me to point out that similar apathy prevails as a rule throughout the land, in urban and rural districts alike. Local governing bodies have practically complete control of the sanitation of their districts, and are, besides, now the directors of education. All our State institutions are, in fact, democratised, and it is certain that unless the great bulk of respectable and responsible citizens will take due interest in their working—unless they will accept office themselves or take at least an active part in getting proper representatives to serve—maladministration and corruption will appear. These local bodies have in their hands the appointments of medical officers under the Poor Law, and Public Health Acts, and it is impossible to expect any real improvement in the present deplorable status of these officers so long as local bodies continue to be largely made up of ignorant and vulgar men, whose object very often is to obstruct the administration of laws which conflict with their own sordid interests. The extreme developments consequent upon the lack of true patriotism in the citizens of a democratic society are now being sufficiently illustrated in the United States. It seems that the same dangers exist at home, and if the spirit of our people cannot be roused we must be prepared in the end for national disaster. This pessimistic forecast will not be deemed exaggerated by serious students of the sociological phenomena of the present day.

I am, Sir, yours truly,

July 1st, 1907. M. O. H.

VOYAGE D'ETUDES MEDICALES.

To the Editor of The Medical Press and Circular.

Sir,—May I call the attention of your readers to the facilities for seeing certain of the French health resorts which are annually offered by the organisation which bears the above title? For the purposes of these visits, France is divided into five districts, each of which contains a large number of spas and mineral-water stations. Every year one of these districts is made the object of a carefully arranged inspection. The time chosen is the first fortnight in September. The party, which is strictly limited to 100 persons, travels under the most favourable conditions. A first-class special train conveys the members from place to place. The hotel accommodation and the food is provided for in advance. The care and transport of the luggage is undertaken by the organisers in such a way that a member's valise left at the proper hour outside his bedroom at the place of departure, is found inside his bedroom at the next halting-place. The advantages of the particular stations visited are explained at each place by Professor Landouzy, who acts as the president of the company. This year the health resorts to be visited are those in the district of the Vosges, which include such well-known places as Contrexéville, Vittel, Martigny, Plombières, Luxueil, and many others. The *rendezvous* is at Reims on August 31st, and the company parts at Divonne, on the Lake of Geneva, on September 13th. Having now taken part in five of these trips, I can assure your readers that there is no more agreeable or instructive manner of spending a part of one's summer holiday. The price (300 francs, or £12) is astonishingly low, especially when it is realised that this includes everything from the *rendezvous* to the *dislocation*. There are no tips or extras of any kind. Medical men and their wives, and medical students, are allowed to join. Those coming from this country are always sure of a particularly warm welcome.

I shall be happy to supplement this information if any of your readers should desire further particulars on the subject.

I am, Sir, yours truly,
Leonard Williams.

8 York Street, Portman Square, W.

OBITUARY.

WILLIAM SCOTT, M.D.Edin., L.R.C.P.Edin.

We regret to record the death on July 2nd, at the age of 78 years, of Dr. William Scott, of Huddersfield. From September last the deceased gentleman had been in indifferent health, and he died from heart failure following passive congestion of the lungs.

Dr. Scott was born at Hexham, and was educated at Newcastle and Edinburgh University. He took the degrees of M.D. and L.R.C.P. in 1860. He afterwards became assistant to Dr. Ramsbotham, at Huddersfield, whose practice he took over at the death of that gentleman. Many years ago he took into partnership Dr. Thornton, of York Place, Huddersfield, and the practice became a very extensive one. Forty years ago he was well known in cricket circles as a good batsman, and played many times against touring All-England elevens. He was one of the founders of the Huddersfield Gentlemen's Club. In politics Dr. Scott was an ardent Liberal, and he was a vice-president of the Huddersfield Liberal Club, but he took no active part in public life. He was a Congregationalist and attended Highfield Chapel, Huddersfield. He leaves two sons and two daughters.

ROBERT SETTLE, M.D.Glasg.,L.R.C.S.Ed., L.S.A., V.D.

We regret to announce the death of Dr. Robert Settle, of Bolton, who passed away last week at the ripe age of 82. He studied medicine at Dublin and at Glasgow, and graduated M.D Glasg. in 1849. Subsequently, he took the L.R.C.S. of Edinburgh, and the L.S.A. of London. He was a native of Bolton, and he practised in that town for sixty years, and held many public appointments. He was an ardent volunteer, and till lately held a commission as Surgeon-Major in the 2nd V.B. Loyal North Lancashire Regiment. He was awarded the volunteer decoration for his long and faithful service. Shortly before his death he resigned the post of Medical Officer and Public Vaccinator to the Bolton Union. He was also Honorary Consulting Surgeon to the Bolton Infirmary and Certifying Factory Surgeon for his district.

CHARLES LATHAM, M.R.C.S., L.S.A.

We regret to record the death at Sandbach, of Dr. Charles Latham, in his 91st year. Dr. Latham had held many public appointments in the district, and was once a famous cricketer. Last year, on the attainment of his 90th birthday, he was presented with a wedding cake with a representation on the top of a bat, wicket and ball, and the inscription, "90 and not out." He qualified M.R.C.S. and L.S.A. as long ago as 1839.

THE LATE DR. E. H. BENNETT.

Referring to our obituary notice of Dr. E. H. Bennett "a colleague and friend" sends us the following note, which we have pleasure in publishing:—By the lamented death of Dr. Edward H. Bennett, Irish Surgery has lost one of its most accomplished representatives, and a link between the present and the past generation has been severed. He was a man of sterling qualities, and had a wide reputation for his intimate knowledge of surgical literature, which freely permeated all his teaching. Although he did not attain to a very extensive practice, nor was he a brilliant operator, he was an acknowledged expert in several branches of surgery, notably in the domain of fractures and dislocations, and his opinion as a consultant in this department was often sought by his professional brethren, and always carried weight. In manner sometimes a little brusque, he was one of the most kind-hearted of men, and few teachers have enjoyed greater popularity with medical students, a class quick to recognise genuine merits. Socially he was a genial host, and excellent companion, and his unfailing good temper carried him serenely through life, and enabled him to meet a trying and prolonged illness with fortitude.

His knowledge of anatomy was sound and accurate, and for many years he filled the post of University Anatomist in the School of Physic, T.C.D., where he conscientiously trained a large number of students.

The writer of this note well remembers the first "demonstration" he received from Dr. Bennett, who unfolded to him the mysteries of the inguinal region, and the perplexing layers of fascia which adorn that region. He was devoted to his work in Sir Peter Dun's Hospital, and it is largely due to his unsparing attention and zeal that the surgical reputation of the Hospital was securely established at the critical time—now many years ago—when it was transformed from a purely medical hospital to a fully equipped Medico-Chirurgical Hospital.

SPECIAL ARTICLE.

IMPERIAL CANCER RESEARCH FUND.

The annual meeting of the general committee of the Imperial Cancer Research Fund was held at Marlborborough House, on Monday, July 1st, H.R.H. the Prince of Wales in the chair. Among those present were Sir William Church, Sir Richard Douglas Powell, Mr. Henry Morris, Sir Henry R. Swanzy, Sir Henry Howse, Sir John McFadyean, Dr. John Tatham, Dr. Rose Bradford, Mr. H. T. Butlin.

The annual report of the Executive Committee described the proceedings of the fifth meeting of the General Committee, held on July 25th, 1906, under the presidency of Lord Strathcona. The General Superintendent took part in a discussion on cancer at the annual meeting of the British Medical Association, held in Toronto, last August. He subsequently proceeded to the United States, and visited many of the important laboratories, including the Rockefeller Institute, in which cancer investigation is being carried out.

In September Dr. Bashford also attended, as the representative of the Imperial Cancer Research, the German International Cancer Congress, held in Heidelberg and Frankfort, of which he was elected one of the Honorary Presidents. Whilst in Germany he was able to obtain a valuable interchange of views with Professor Ehrlich and others engaged in the investigations on cancer.

Since that meeting a communication had been received from some of the German representatives proposing the establishment of a permanent international conference on cancer, and forwarding an outline scheme of organisation, with its headquarters in Berlin. The General Superintendent was asked to organise a British branch and to become one of the representatives, but he was of opinion that at present little advantage was to be gained by such a conference.

The General Superintendent and staff had been continuously engaged in investigation, and a considerable number of new facts had been ascertained. They were not, however, yet ready for publication in the form of a third scientific report. The progress of the investigations was recorded in the papers from the laboratory.

A grant had been made to Mr. W. Sampson Handley towards the expenses of an investigation into the mode of growth and dissemination of cancer of the stomach. The Government of Cape Colony had forwarded an important report of a Committee of the House of Assembly appointed to investigate certain reputed cancer cures, principally consisting of herbal remedies. Dr. Sidney Martin, F.R.S., had been re-elected a member of the Executive Committee by the Royal College of Physicians. Sir John Tweedy and Mr. Edmund Owen had been elected by the Council of the Royal College of Surgeons to fill the vacancies on the Committee occasioned by the expiration of Mr. John Langdon's period of office on the council, and by Mr. Henry Morris becoming *ex-officio* a member of the Committee, in virtue of his appointment as President of the Royal College of Surgeons, whilst Mr. Henry T. Butlin was also re-elected a member of the Committee by that College. Dr. Rose Bradford was again nominated by the Royal Society as their representative on the Committee, The Committee once more expressed its appreciation of valuable services rendered by the Foreign, Colonial, and India Offices in obtaining and forwarding information relating to cancer throughout the Empire.

In December the Committee received from one of the vice-presidents, Mr. H. L. Bischoffsheim, an intimation that he intended to give a donation of £40,000 in commemoration of his golden wedding. This munificent gift, which was warmly acknowledged by the Committee, was particularly gratifying as evidence of the confidence felt by the donor in the efforts being made by systematic scientific investigation to arrive at a more exact knowledge of the nature, causes and treatment of cancer.

The General Superintendent's Report was then read.

Honorary Treasurer's Report.

The report of the Honorary Treasurer for the year ending June 24th, 1907, stated that in August, 1906, the Fund was increased by a donation of £1,000 received through His Royal Highness the President from an anonymous donor. This was followed in December last by the munificent donation of £40,000 from Mr. and Mrs. Bischoffsheim on the occasion of their golden wedding.

The amount in donations and subscriptions received during the year, apart from the Bischoffsheim Fund, was £3,515 11s. This compared favourably with the amount (£2,315 2s.) received during the year 1905-6. Special reference was made to the gift of £600 received through Sir Samuel Wilks, Bart., F.R.S., to the gift of £500 from Miss Black, to the sum of £120 from the Government of Hong Kong, which represents the subscription of £30 per annum for the years 1904-7 inclusive which was obtained through the good offices of the Governor, Sir Henry A. Blake, G.C.M.G. In addition to several fresh donors of varying sums, eight new annual subscribers had been added to the list this year, one of whom was the Worshipful Company of Carpenters. This was the first City company to become an annual subscriber. The Worshipful Company of Pewterers had, however, given a third donation. At the present time there were eighteen annual subscribers. The Fund was still deficient to the extent of nearly £13,000 on the estimated amount required to provide a sufficient and permanent income from invested capital.

Sir William Church moved the adoption of the report.

Sir Henry R. Swanzy, in seconding the motion, said the thanks of all were due to Dr. Bashford and his assistants for the sustained, well-directed and skilful efforts made by them to solve the many problems surrounding the subject of cancer. Substantial progress was being made, and they believed that nothing which scientific skill could devise was being omitted to solve this problem.

The resolution was carried unanimously.

Sir Julius Wernher proposed a vote of thanks to the Chairman and members of the Executive Committee, the Sub-committees, the Honorary Treasurer, the Secretary, Auditor, and others who had assisted in the work of the Fund during the past year. It was sometimes said that the work of the Fund was, perhaps, slow; but very few people recognised the nature of this scientific difficulties which had to be surmounted.

Mr. H. L. Florence seconded the motion, which was unanimously agreed to.

The Bischoffsheim Donation.

Mr. Henry Morris next moved :—"That the General Committee desire to place on record their deep sense of gratitude to Mr. and Mrs. Bischoffsheim for their recent munificent gift of £40,000, which, together with Mr. Bischoffsheim's original donation of £5,000, will do so much towards placing the Imperial Cancer Research Fund on a secure financial basis."

Sir Charles Morrison Bell seconded the motion, which was passed unanimously.

On the motion of Dr. Rose Bradford, seconded by Mr. Ludwig Neumann, Mr. Watson Cheyne was re-elected a representative of the General Committee on the Executive Committee; and on the motion of Mr. Butlin, seconded by Sir John McFadyean, Sir John Tweedy was elected a member of the General Committee.

Sir R. Douglas Powell proposed a vote of thanks to the Prince of Wales for presiding.

Mr. Edmund Owen seconded the motion.

The motion was passed with applause.

The Prince of Wales, in reply, said it was a great pleasure to him to have been able to preside at the meeting. They had every reason to be satisfied with the growing confidence of the public in the work of the Fund. The broad lines of inquiry undertaken by the Imperial Cancer Research Fund, had, they felt certain, influenced the whole nature of investigation at home and abroad. It was recognised that the work was conceived and carried out in a liberal spirit; that whatever facts were ascertained were immediately made known to every one; that the material was freely placed at the disposal of all qualified to use it to good advantage; that their staff was not working for its own ends, but with a whole-hearted desire to help on a solution of the problem. Another tribute to the success of the efforts of the Fund was the number of applications from skilled investigators to take part in the work. Thanks to the liberality of the Royal Colleges, further accommodation had been placed at the disposal of the General Superintendent, and he had, therefore, been enabled to add materially to the staff.

His Royal Highness concluded by expressing his thanks to the chairman and members of the various committees, Dr. Bashford, and the officers of the Fund, for the valuable and untiring services which they had given during the past year to the work of the Fund.

MEDICAL NEWS IN BRIEF.

Royal College of Surgeons, England.—Annual Election to the Council: a Record Poll.

The annual meeting of Fellows of the Royal College of Surgeons of England took place last Thursday for the purpose of electing four Fellows into the Council of the College. The President, Mr. Henry Morris, occupied the chair, and appointed Mr. Willmott Evans and Mr. T. Crisp English, who kindly offered their services, to act as scrutineers for the occasion. After the secretary had read the list of candidates, the President declared the poll open for two hours, for the convenience of those Fellows desiring to vote in person. Only fourteen Fellows, however, voted in this manner, no fewer than 878 Fellows recording their votes by post. The poll proved to be a record one. At the conclusion of the counting the President declared the result of the poll to be as follows :—Mr. C. J. Symonds, Guy's Hospital, 452 (26 plumpers); Mr. Wm. Bruce Clarke, St. Bartholomew's Hospital, 413 (52 plumpers); Mr. C. Mansell Moullin, London Hospital, 403 (6 plumpers); Mr. Frederic Eve, London Hospital, 388 (3 plumpers); Mr. H. W. Page, St. Mary's Hospital, 349 (11 plumpers); Mr. W. D. Spanton, Hanley, Staffs, 348 (34 plumpers); and Mr. Charles Higgens, Guy's Hospital, 234 (10 plumpers). The President then declared Messrs. Symonds, Clarke, Moullin, and Eve duly elected members of the Council. The scrutineers found three balloting-papers to be invalid, and three arrived too late.

Society of Physicians and Surgeons of the Society of Apothecaries, London.

The first dinner of this newly-formed society was held in London last week at the Restaurant Frascati, to celebrate the obtaining of the Act of Parliament which received the sanction of his Majesty the King on July 4, 1907, the day of the banquet. This act confers the title of "Licentiate in Medicine and Surgery" on its members, since June, 1887. There were present the President, Dr. Rivers Willson and Lady Willson, the Ex-president, Dr. Percy Lodge, the Vice-president, Dr. McCorner, J.P.

Dr. Parker Young, the Master of the Society of Apothecaries, the Senior Warden, Dr. G. Willes, and the Junior Warden, Dr. F. G. Brown, were the guests of the evening. The representatives of the Society of Apothecaries present were Sir Hugh Beevor, Bart., Dr.

Gerald Dalton (the Hon. Treasurer), and Dr. S. H. Green, Dr. Marsh, Mr. L. Darlington, Dr. Horace Saunders and Mrs. Saunders, Dr. George Brown (late of the General Medical Council), and Mr. M. Upton (Clerk to the Society), and many others.

After the Royal toasts had been duly honoured, the President gave the toast, "The Association of Physicians and Surgeons," introducing in his remarks a *resume* of the work done in the obtaining of this Act of Parliament. The next toast was "The Master Wardens and Court of Assistants of the Apothecaries Society," who had influentially furthered the movement, which was duly honoured and responded to by Dr. Parker Young (the Master). Dr. Geo. Brown gave the toast of "The General Medical Council, and its Reform," Sir Hugh Beevor responding. Then followed "The President and Officers," proposed by Dr. G. W. B. Marsh, who alluded to the founding of the Society some years ago by Dr. Percy Lodge. Dr. Rivers Willson responded, and also made allusion to the good work done by Dr. Lodge, and said that that gentleman had according to the rule vacated the Presidentship on his becoming a Fellow of the Royal College of Surgeons. Dr. Lodge also responded, and said that some six years ago he had the honour of being received by the then Master and Wardens of that Society on these matters, and received much support from Dr. Parker Young and the Court of Assistants. He congratulated Dr. R. Willson, the President, on the good work he had done in his years of office, and that the Society of Physicians and Surgeons had been able to attain so much of the object they had in view. M. and Madame Cokhinis and their son gave a very excellent musical programme during the evening, which was much appreciated.

Royal Army Medical Corps.

At a recent inspection by Col. A. T. Sloggett, C.M.G., Principal Medical Officer of the London District, of the Companies as well as the bearer companies of the 1st, 2nd, and 3rd London Infantry Brigades, numbering about 400, the column was accompanied by an ambulance and transport train of eight wagons, a cyclist section, and a couple of ambulance dogs trained by Major Richardson, who was present with the corps, to which he has been attached. A field ambulance was pitched, and a demonstration was given of carrying patients in cacolets and on horse-back. The inspection was attended by the War Minister, Mr. Haldane, who showed great interest in the programme of work carried out by the troops. Among the other officers present was Col. J. Cantlie, F.R.C.S., the honorary colonel and organiser of the corps.

Royal College of Surgeons, England.—Vacant Examinership.

The period of office of Mr. C. H. Golding-Bird on the Court of Examiners of the Royal College having expired, the Council will proceed to elect a successor on the 25th instant, Mr. Golding-Bird having notified his intention not to seek re-election. A vacancy on the Board of Examiners in Dental Surgery is also announced; Mr. B. Pateman, the present examiner, whose period expires, is eligible for re-election, and will offer himself for the post. Applications for either appointment must be sent in to the Secretary, S. Forrest Cowell, Esq., on or before the 17th instant.

St. John's Hospital for Diseases of the Skin, Leicester Square.

The annual competition for the Chesterfield Silver Medal (which was instituted in 1895, by the Earl of Chesterfield, President of the Hospital) took place on May 24th, and the Medal has been awarded to E. J. D. Mitchell, M.A., M.B., B.C., for proficiency in Dermatology.

Epsom College.

The annual general meeting of the governors of Epsom College took place last week at 97 Soho Square, London, W., under the chairmanship of Mr. Henry Morris (President of the Royal College of Surgeons). Among those present were Sir R. Douglas Powell, Sir William S. Church, and Sir C. Holman. The chairman announced the foundation of the Robert Armstrong scholarship of £60 a year for classics, and of the R. R. Cheyne annuity for the daughters of medical men who are Protestants. Three pensioners and seven foundation scholars were elected, and at a meeting of the council, held immediately after, two pensioners in addition to the foregoing were admitted, vacancies having arisen.

PASS LIST.

University of London.

The following candidates have passed the M.B., B.S. Examination:—

With Honours.—Harold Garfield Bennett, St. Thomas's Hosp. (*a*); Gerald Tyler Burke, St. Barth. Hosp. (*c*); Bertram Walter Cherrett, St. Barth. Hosp. (*e*); John Henry Farbstein, University Coll. (*d*); John Athelstan Braxton Hicks, Westminster Hosp. (*b*); William Henry Miller, Guy's Hosp. (*d*); Henry John Nightingale, St. Thomas's Hosp. (*a*, *b*, *c*, *d*, *University Medal*); Alfred Chas. Foster Turner, St. Thomas's Hosp. (*b*.); Charles Wilfred Vining, St. Mary's Hosp. (*a*). (*a*) Distinguished in Medicine. (*b*) Distinguished in Pathology. (*c*) Distinguished in Forensic Medicine and Hygiene. (*d*) Distinguished in Surgery. (*e*) Distinguished in Midwifery and Diseases of Women.

Ordinary Pass.—Godfrey F. E. Allison, Charles J. Armstrong-Dash, John S. Avery, Alfred Ball, Alec Barber, Tom Bates, Ella Beales, Sylvia R. M. Blackstone, Mary A. Blair, John F. Broughton, Stanley W. R. Colyer, Eustace J. C. Dicks, Kenelm H. Digby, Allan B. Fearnley, John Ferguson, Kenneth M. Gibbins, Elliott T. Glenny, Samuel L. Graham, Arthur D. Griffith, Leopoldine W. D. Griffiths, Sidney W. Grimwade, George Hamilton, Horace B. Hill, Frank N. S. Hitchcock, Frank P. Hughes, Gwilym G. James, Sidney H. J. Kilroe, Herbert S. Knight, Janet Lane-Claypon, D.Sc., Alexander Manuel, Marian Mayfield, Emily H. Morris, Frederic M. Neild, Geoffrey E. Oates, Catherine Payne, August F. Perl, Arthur J. S. Pinchin, John M. Plews, David Ranken, Frank D. Roberts, Cecil F. Robertson, Francis W. Schofield, Henry J. Smith, Ronald E. Todd, James A. Torrens, Stuart W. J. Twigg, Joseph Unsworth, Thomas W. Wade, Norman H. Walker, Thomas E. Walker, Robert J. Waugh, David Wilson, Alfred W. G. Woodforde, Carl E. Zundel.

B.S. Examination (for students who graduated in Medicine in or before May, 1904).—John Acomb, Dora E. L. Bunting, Edward C. B. Ibotson, Rees Phillips, Frank Tratman, M.D., Hilda K. Whittingham.

Trinity College, Dublin.

The following candidates passed the Final Medical Examination (Trinity Term), Part II., Surgery:—William Pearson, Robert E. Wright, Richard G. S. Gregg, Allman J. Powell (passed on High Marks); William E. M. Armstrong, Frederick Stevenson, Henry de C. Dillon, Oliver St. J. Gogarty, Thomas B. W. MacQuaide, Reginald Holmes, Wallace D. Mitchell, James C. C. Hogan, Madeleine S. Baker, Charles H. O'Rorke, James E. M'Farlane, Joseph C. Ridgway, William A. R. Spong.

Final Examination.—Part III.—Midwifery.—Frank R. Seymour, Henry de C. Dillon and William A. R. Spong (equal), William E. M. Armstrong, Robert de C. Wheeler, Arthur E. Knapp, Thomas P. Dowley John H. Waterhouse, Alfred H. Smith.

University of Birmingham.

The following is a list of the successful candidates in the Faculty of Medicine at the examinations held June, 1907:—

Degree of Doctor of Medicine.—Leonard George Joseph Mackey.

Degrees of Bachelor of Medicine and Bachelor of Surgery for Past Students of Birmingham Medical School.—William Frederick Ewart Ashton. *Under Ordinary Regulations.*—Herbert Charles Horace Bracey, *†James Fenton, Philip James Mason, Nevill Coghill Penrose, Arthur Addison Sanders, Arthur John Smith, Rupert Wesley Thompson, Herbert Henry Warren. (*Queen's Scholarship. † Ingleby Scholarship.)

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT PATHOLOGICAL LITERATURE.

Mode of Spread of the Meningococcus.—Fraser and Comrie (*Scottish Medical and Surgical Journal*, July, 1907) report the result of their inquiry into the mode of spread of infection during the recent outbreak of cerebro-spinal meningitis at Leith. They are led to agree with the conclusion of Ludwig Jehle that although children most commonly suffer, they are not to any extent carriers of the disease. Jehle, from his investigations during the epidemics in Silesia and in the Rhine coal-fields, suggested that the real carriers of infection in those provinces were miners who, bringing the organisms from an infected pit, passed it on to their children. Substituting dock-labourers for miners, and ship-holds for coal-mines, Fraser and Comrie hold similar views in regard to the recent epidemics at Leith and other sea-port towns in the kingdom. The question has to be decided, however, of the manner in which the meningococcus can be carried without infecting the carrier. Fraser and Comrie examined the naso-pharynx in 13 cases of the disease, and in 69 cases of intimate contact. The meningococcus was present in 2 of the 13 cases (15 per cent.), and in 10 of the 69 cases (14 per cent.). Of the 69 cases, 15 were fathers of affected patients, the remaining 54 being mothers, brothers, sisters, and other intimate associates. Of the 10 contacts in whom the meningococcus was found, 5 were fathers of patients. Thus, while the organism was found in 33 per cent. of the fathers, among others contacts in as close intercourse it was found in only 9 per cent. The fathers appeared, therefore, to be especially prone to have the meningococcus in the naso-pharynx, although they did not themselves contract the disease. Of the 15 fathers examined, 5 were employed in overhauling the same ship; the meningococcus was recovered from the air in the engine-room. In several other fathers the naso-pharynx was found to contain gram-negative diplococci, but owing to the excess of saprophytic organisms isolation was impossible. In the case of 23 controls, who had no connection with the disease, the naso-pharynx was examined for the meningococcus with negative results. Fraser and Comrie summarise their conclusions:—(1) That dusty, ill-ventilated atmospheres, which provide conditions favourable to the growth of the meningococcus and to the occurrence of naso-pharyngeal catarrh, are often associated with the dissemination of epidemic cerebro-spinal meningitis. (2) The high comparative proportion of fathers, whose naso-pharynx was found to contain the meningococcus, suggests that they are the carriers of disease to their children. (3) The chief incidence of the disease in the Leith epidemic was among children of the lower classes, a point in favour of naso-pharyngeal infection. (4) Infection of the naso-pharynx is an important factor in spreading the disease. (5) It is advisable to isolate all contacts, and to carry out a bacterioscopic examination of the nose and naso-pharynx. It should be added that Fraser and Comrie relied for the bacteriological diagnosis of the organism on the characteristics described by Gordon in his recent report to the Local Government Board. R.

Muscular Tuberculosis.—Kirmisson (*Bulletin de l'Académie de Médecine*, No. 6, 1907) and Cornil (*id.*, No. 8, 1907) report cases of this rare condition. In Kirmisson's case, a child, æt. 10, presented numerous fusiform nodules scattered through the muscles of both lower limbs. The glandular system was also widely affected. The nodules were found on microscopic examination to consist of masses of epithelioid and giant cells, embedded in fibrous capsules. Bacteriological examination by smear, by culture, and by inoculation, was entirely negative. In Cornil's first case, a nodule, of the size of a hazel-nut appeared in the masseter muscle; microscopically, it was a conglomerate tubercle, showing typical structure, with commencing caseation. His other case was of more usual type—cold abscess in the muscles of the thigh, unconnected with any disease of bone. R.

The Bacteriology of Cerebro-Spinal Meningitis.—In view of the very varied descriptions of the meningococcus which still find place in the text-books, it is important that the careful observations of recent investigators should be on record. We, therefore, call attention to a paper by Symmers and Wilson on the cultivation of the meningococcus in the Belfast epidemic (*British Medical Journal*, June 22, 1907). They examined 75 cases, either *postmortem*, or by lumbar puncture during life. In 52 of these, the meningococcus was separated from the spinal fluid. They examined the blood of 15 patients during life, and found the organism in 3 cases. They identify the organism by the following characteristics: (1) The colonies on suitable agar (agar with ascitic fluid and peptone) are smooth, circular discs, grey in colour, translucent, closely resembling colonies of B. coli communis. The colonies are, when first discovered, always discrete. (2) The colonies consist of cocci indistinguishable in size and shape from gonococci. In the older cultures many organisms, spherical in shape, and closely resembling staphylococci, are found. (3) The organism is negative to Gram's stain, although in every culture a few cocci are found which retain the stain with considerable persistence. (4) The organism does not grow at 20° to 22° C. (5) Media containing dextrose and maltose are fermented by the growth, acid being produced, whereas galactose and saccharose remain unchanged. The authors find that the meningococcus grows readily, but during the earlier generations *in vitro* sub-cultures should be made every day. R.

Some New Facts about Agglutination.—Miss Fisher (*Journal of Medical Research*, May, 1907) publishes the results of a careful study of agglutination with special reference to the agglutinins of the various types of dysentery organisms. Some of her conclusions have a general bearing. (1) The use of more than one organism in animal immunisation tends to reduce the agglutinins produced for each of the inoculating organisms. Miss Fisher suggests that this is due either to over-stimulation of the cell due to the action of so many organisms, or to the likelihood that a cell is capable of producing only a certain number of agglutinins. When two or more organisms are used, the number of agglutinins being limited must be divided between these organisms, resulting in a decrease in the agglutination of each. (2) The simultaneous inoculation of various types of organism produces specific agglutinins for each organism, but not in as great quantity as when each organism is injected separately. (3) The agglutination reaction has a very limited value in the differentiation of types of intestinal organism, and has none in distinguishing the various dysentery bacilli. R.

Hæmolytic Properties of Organ and Tumour Extracts.—Weil (*Journal of Medical Research*, May, 1907) attempts to discover the factors giving rise to the anæmia occurring in cases of malignant disease. He first examined the hæmolytic properties of extracts of organs. In this respect he concludes: (1) Extracts of normal organs (liver and kidney) cause hæmolysis of the red cells of the same species of animal, or even of the same animal, but the hæmolytic power varies considerably, or may be altogether absent. (2) If the organ be thoroughly freed from blood, the hæmolytic power is greatly diminished, or altogether lost. (3) Addition of entire blood, or, separately, of leucocytes and serum, to the bloodless organ extracts, diminishes their hæmolytic activity, but addition of red blood cell extract increases the activity of bloodless organ extracts. (4) It is the red blood cell extract *plus* the hæmolytic principle of the organ extract which causes hæmolysis. With regard to tumours, Weil concludes: (1) Tumours differ greatly in their hæmolytic activity, according as they are necrotic or non-necrotic. (2) Non-necrotic tumours are much less auto-hæmolytic than are necrotic tumours. (3) The hæmolytic activity of non-necrotic tumours can be increased by addition of red blood cell extract. (4) The hæmolytic activity of necrotic tumours is not increased by the addition of red blood cell extract. (5) The anæmias of malignant tumours are probably due in part to the hæmolytic and toxic action of the products of necrosis. R.

A Theory of Colour Vision.—Pretorius (*Dublin Journal of Medical Science*, April, 1907) puts forward a theory of colour vision which deserves consideration. He regards the cones of the retina as made up of a series of segments, each of which has the property of perceiving its particular colour, the visual sensation being set up by molecular vibration. When all the segments are equally stimulated, white light is perceived. In support of this, Pretorius points out that many of the white rays falling on the lens are dispersed, and that, therefore, the different spectral rays must strike the cone at different segments of its length. We see the light as white, however, in spite of its dispersion, and this synthesis is best explained by his hypothesis. Pretorius adduces many facts which are consistent with his theory but he admits the absence of the possibility of experimental proof. R.

Atypical Leukæmia.—Rychlik (*Zenhalblatt fur Inn. Med.* No. 22, 1907., p. 562) writes on this subject, and describes the case of a youth, æt. 18, who for two months had suffered from a splenic tumour, and who, during nine months was jaundiced, and had pain in the region of the gall bladder, though with normally coloured stools. Hæmic cardiac murmurs were present, but there was no glandular enlargement and no pain over the long bones. The blood examination gave 3,624,000 red corpuscles; 15,600 white cells; and 50 per cent. hæmoglobin. The plasma was coloured yellow with bilirubin, and some normoblasts and myelocytes were detected. The diagnosis made was that of Banti's disease in the second stage, and a splenectomy was performed. Six hours after operation the red cells numbered 6,050,000 per ccm.; the leucocytes 31,280 per ccm.; and the hæmoglobin was 65 per cent. Twenty-four hours after the operation the numbers were:—Red cells 6,104,000; white cells 25,600; hæmoglobin 65 per cent. The patient died shortly afterwards, and the autopsy showed general hypertrophy of the mesenteric glands, and of the intestinal lymphatic tissues; a lymphoid state of the bone-marrow; partial myeloid alteration of the spleen, and islets of myeloid cells in the kidneys. The writer criticises the latest views of Banti's disease, and identifies the condition with Maixners' hæmorrhagic cirrhosis of the liver. He regards the leukæmias as quite distinct from infectious granulomata, and more inthe nature of specific re-actions to definite irritants. M.

Contraction of the Stomach in Polyserositis.—Scery (*Archiv. fur Verdaungskrankh*, Bd. xivi. heft 1), as the result of a microscopical and macroscopical examination of a case of the above, comes to the following conclusions:—Simple inflammatory contraction of the stomach is a disease *sui generis*. The cause in most observed cases has been chronic hyperæmia in diseases of the heart. It consists essentially of a chronic inflammatory hypertrophy of the connective tissue in the serous and submucous coats. In the sclerosed tissue the blood vessels and lymphatics become narrowed, and further one often finds a chronic inflammation of the gastric glands, with increase of the connective tissue between them. A similar fibrous hyperplasia may occur in cases of chronic inflammation, such as is set up by alcohol or syphilis. M.

Diabetic Lipæmia.—Klemperer and Umber (*Zeitschr. f. Klin. Med.*, Bd. 61, L. 145) state that lipæmia is not characteristic of severe diabetes or of diabetic coma alone, but is to be found in about one half of all cases. It depends in part upon a real increase of the cholesterin and lecithin, and only in some cases to an actual increase in the fat of the blood. In two cases examined, for example, the amount of fat present was from .4 to .6 per cent., which is hardly up to the normal; whilst the cholesterin percentage was 3 to 4 times normal, and in one case more than 10 times normal. Owing to the fact that the subcutaneous and mesenteric fat is not rich in cholesterin, this condition cannot be explained as being due to a simple fat transport from one part to another. The authors think that it must be due to the excessive destruction of fatty substances in nerve tissue, or to the breaking down of proteid-containing tissues. M.

The Influence of Coloured Lights upon Blood-pressure.—Spiston has carried out a series of experiments on the above subject. They were made for the most part upon young men of from 23 to 25 years of age and the exposures took place either after the individual had been for some time in diffuse daylight or in complete darkness. The following were the more important results:—(1) The blood pressure sinks progressively under the influence of red and green light. This fall takes place rapidly, and soon reaches a minimum at which it remains almost stationary. (2) The blood pressure under the influence of blue light at first rises, but only slightly, and then falls, but not to so low a level as with green or red light. (3) On returning to daylight after exposure to coloured lights, the blood pressure rises and reaches the normal level in about ten minutes. (4) On going into the dark after exposure to daylight the pressure sinks slightly, but not to so low a level as with any of the coloured lights mentioned above. (5) Red and green light following blue light produces a fall in pressure, while blue light after red or green causes a rise in blood pressure. M.

King Edward's Hospital Fund.

Amongst the latest contributions received at the Bank of England for King Edward's Hospital Fund for London are the following:—Annual subscriptions: Messrs. Coutts and Co., £250; Messrs. Glyn, Mills, Currie, and Co., £250; Mr. Cecil H. Oliverson, £250; the Duke of Westminster, £100; Sir H. Seymour King, M.P., £50. Annual subscription to additional permanent income fund: Viscount Iveagh, K.P., £500.

North-East London Clinical Society.

The annual meeting of this popular society was held on July 4th, the President, Dr. Arthur E. Giles, being in the Chair. The following officers were elected for the year 1907-8:—President, Dr. M. C. Corner. Hon. Treasurer, Mr. Herbert W. Carson. Hon. Librarian, Dr. A. J. Whiting. Hon. Secretaries, Drs. G. P. Chappel and G. R. Plaister. After the report of the Council and the balance-sheet for the past session had been adopted, the meeting resolved itself into a social gathering, which was well attended by the members, including ladies.

The new City of London Lying-in Hospital, City Road, was opened on July 1st by Princess Christian. Her Royal Highness was received by the consulting physician (Dr. C. Godson), the consulting surgeon (Mr. J. Langton), and other members of the reception committee, by whom she was escorted over part of the new buildings.

NOTICES TO CORRESPONDENTS, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessary for publication but as evidence of identity.

A. M. S.—The quotation you ask for comes from the preface of Stevenson's poems. It runs as follows:—"There are men, and classes of men, who stand above the common herd; the soldier, the sailor, and the shepherd not unfrequently; the artist rarely, rarer still the clergyman; the physician almost as a rule. He is the flower (such as it is) of our civilisation, and when that stage of man is done with, and only remembered to be marvelled at in history, he will be thought to have shared as little as any in the defects of the period, and most notably exhibited the virtues of the race. Generosity he has, such as it is possible to those who practise an art, never to those who drive a trade; discretion tested by a hundred secrets; tact tried in a thousand embarrassments; and what are more important, Heraclean cheerfulness and courage. So it is that he brings air and cheer into the sickroom, and often enough, though not so often as he wishes, brings healing."

Mr. Thorne Baker's paper is unavoidably held over until our next.

ACCIDENT INSURANCE TO MEDICAL MEN.

A corresponent asks if subscribers to this journal are insured against accident and death. Our reply is that it is not necessary for a journal of the standing of The Medical Press and Circular to attract subscribers by these methods, as every medical man who uses an ordinary sixpenny or shilling diary, is insured against accident and death without cost to himself if he will only take the trouble to read and carry out the instructions of the coupon which is to be found in almost every diary published. Thus, if the coupon be filled in, and the possessor be killed in a railway acident, his representatives can claim £1,000. If killed by tramway, omnibus, or cab accident, £500, while, in the case of non-fatal accidents, smaller sums are paid, according to injuries, and weekly allowances in other cases.

Compensation.—Our correspondent can insure his coachman, as well as his horse and carriage, in "The Imperial Accident and Live Stock Insurance Company," 17, Pall Mall, London.

O. F. H. (Glasgow).—The new work on anatomy by Prof. A. M. Buchanan would best answer your purpose, as it embraces both systematic and practical teaching, and is particularly well illustrated.

C_2H_5OH.—The question is really one for a lawyer, but we may refer you to the Habitual Drunkards Act, 1879, which allows a separation to be applied for by a woman whose husband is an habitual drunkard. In case of a husband, a separation could be obtained by the Licensing Act, 1902, which included drunkenness as one of the causes for separation under the Summary Jurisdiction (Married Women's) Act, 1895.

Meetings of the Societies, Lectures, &c.

Wednesday, July 10th.

Dermatological Society of London (11, Chandos Street, Cavendish Square, W.).—5.15 p.m.: Meeting.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. H. L. Barnard: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. W. Langdon Brown: Sudden Death.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—2.30 p.m.: Skin (Dr. Meachen), Eye (Mr. Brooks), Medical Out-patient (Dr. Whipham).

Thursday, July 11th.

British Gynæcological Society (20, Hanover Square, W.).—8 p.m.: Exhibition of Specimens.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical).

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.)—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques:—Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson). 3 p.m.: Medical In-patient (Dr. Chappel).

Hospital for Sick Children (Great Ormond Street, W.C.)—4 p.m.: Lecture:—Dr. Thursfield: The Diagnosis, Prognosis, and Treatment of Pleural Effusions in Children.

Saturday, July 13th.

Incorporated Society of Medical Officers of Health (Town Hall, Colchester).—11.15 a.m.: Paper:—Dr. W. G. Savage (President of the Eastern Counties Branch): Recent Work upon the Bacteriology of Typhoid Fever in its Relationship to Preventive Measures.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. W. Dodd: Clinique. (Eye.)

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—9.30 a.m.: Clinique:—Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. Leslie).

Vacancies.

Ayr District Asylum.—Junior Assistant Physician. Salary, £120 per annum, with board, apartments and laundry. Applications to the Medical Superintendent.

West Suffolk General Hospital, Bury St. Edmunds.—House Surgeon. Salary, £100 per annum, with board and lodging. Applications to the Secretary.

Egypt.—Sub-Inspector of Ophthalmic Hospitals. Salary, £500 per annum, with two months' salary in lieu of travelling expenses to and from England. Applications to A. F. MacCallan, Esq., 32 Bedford Gardens, Kensington, W.

Stockton and Thornaby Hospital, Stockton-on-Tees.—House Surgeon. Salary, £180 per annum, with residence, board and washing. Applications to H. G. Sanderson, Secretary, Exchange Offices, Stockton-on-Tees.

Monmouthshire Asylum, Abergavenny.—Senior Assistant Medical Officer. Salary, £250 per annum, with board, furnished apartments, washing and attendance. Applications to the Medical Superintendent.

Middlesex Hospital, W. (Cancer Department).—Medical Officer and Registrar. Salary, £100 per annum, with board and residence. Applications to F. Clare Melhado, Secretary-Superintendent.

Rotherham Hospital and Dispensary.—Senior House Surgeon. Salary £100 per annum, with rooms, commons, and washing. Applications to the Secretary, H. Kelson, Masonic Buildings, High Street, Rotherham.

Appointments.

David, John, M.B., C.M.Glasg., a District Medical Officer by the Neath (Glamorganshire) Board of Guardians

Ewing, J. Millar G., L.R.C.P. and S.Edin., House Surgeon to the Wallasey Dispensary and Victoria Central Hospital, Liscard.

Gunning, Charles John Hope, M.R.C.S., L.R.C.P.Lond., Anæsthetist to the Victoria Hospital for Children, Tite Street, Chelsea, S.W.

Logan, Frederick Thomas Bishop, L.R.C.P., L.M.Edin., M.R.C.S., Medical Officer for the Bishopsworth District of the Long Ashton (Somerset) Union.

Macphail, Alexander, M.B., M.S.Glasg., Lecturer on Anatomy at the Charing Cross Hospital Medical School.

Robbs, C. H. D., M.B.Lond., Certifying Surgeon under the Factory and Workshop Act for the Grantham District of the County of Lincoln

Rynne, M. A., M.D.Dub., Certifying Surgeon under the Factory and Workshop Act for the Cheltenham District of the County of Gloucester.

Symes, J. Odery, M.D.Lond., Physician to the Bristol General Hospital.

Chiles-Evans, David Brynmor, L.R.C.P.Lond., M.R.C.S., Assistant Medical Officer at the Swansea Workhouse.

Colyer, Stanley, M.B., B.S.Lond., D.P.H., House Physician at the General Lying-in Hospital, York Road, Lambeth.

Coombs, Carey, M.D.Lond., Assistant Physician to the Bristol General Hospital.

Births.

Dodgson.—On July 2nd, at Sherburn House, Durham, the wife of G. S. Dodgson, M.B., of a daughter.

Hayes.—On June 27, at Dunvegan, Longton Grove, Sydenham, the wife of J. Hayes, L.R.C.P.I., of a daughter.

Owen-Taylor.—On July 6th, at Cherwell House, Nottingham, the wife of Herbert Owen-Taylor, M.D., of a daughter.

Marriages.

Dickins—Taunton.—On June 26th, at St. Nicholas, Worcester, Sidney John Oldacres Dickins, M.D., of Cowfold, Sussex, to Cicely Margaret, elder daughter of W. W. Taunton, B.Sc., M.R.C.P., of Worcester.

Giles—Cooper.—On July 4th, at St. James's Church, Kidbrook, Blackheath, Hubert Mathieson, elder son of Captain H. Giles, R.N., of Little Heath, Alverstoke, Hants, to Florence Muriel, only daughter of Peter Cooper, L.R.C.P.Lond., M.R.C.S.Eng., of Stainton Lodge, Blackheath.

Kenyon—Kilroy.—On July 3rd, at All Saints' Church, Ryde, Leslie Kenyon, to Daisy, youngest daughter of the late Philip Le Feuvre Kilroy, Lieut.-Colonel., R.A.M.C., and Mrs. Kilroy, Fairfield, Ryde.

Stockdale—Bultin.—On June 29th, at St James' Church, Dundee, Natal, Frederick Risley, ninth son of the late Charles Carrington Stockdale, of Highbury, of H.M. Civil Service, to Gertrude Eveline, elder daughter of Charles Henry Butlin, M.R.C.S., of Plymouth, late of Camborne, Cornwall.

Webster—Murphy.—On July 3rd, at St. Mary Shandon Church, Cork, the Rev. James Henry Webster, fifth son of George Webster, of Bandon, to Harriet Dora, only daughter of the late Major F. H. S. Murphy, M.D., R.A.M.C., and of Mrs. Murphy, Cork.

Deaths.

Davey.—On July 5th, at Havering House, Abergavenny, Norris Fasham Davey, M.R.C.S., L.R.C.P., late of Romford, Essex, in his 88th year.

Forshall.—On July 6th, at 12, Southwood Lane, Highgate, Francis Hyde Forshall, M.R.C.S., aged 74.

Kelly.—On June 29, at 13, Mellifont Avenue, Kingstown, co. Dublin, suddenly, from heart failure, Lieut.-Colonel James Bennett Kelly, R.A.M.C., Retired.

Lloyd Owen.—On July 4th, at Kent Lodge, Southsea, Alfred Lloyd Owen, M.D., aged sixtyone years.

VOL. CXXXV. WEDNESDAY, JULY 17, 1907. No. 3

NOTES AND COMMENTS.

Surgeon and Butcher.

Notes and Queries has lost none of its interest even though the hand of its founder and editor has alas! been removed. A correspondence has been learnedly and briskly raging in its columns of late as to whether the alleged custom of not putting surgeons and butchers on juries to try murder cases ever had a *de facto* existence, and, if so, what was its origin. It seems doubtful whether a regular custom actually existed, but there seems to have been some feeling on the subject, the alleged reason being that surgeons and butchers were so much habituated to cruelty that they would not be good judges of the moral enormity of murder. Surgeons to whom the information comes as news will, we hope, be duly appreciative of their association with butchers in this connection, and still more so of their supposed brutality. In the innocence of our hearts we have hitherto believed that the medical men are excused jury service in recognition of their arduous toil for the benefit of our common humanity, and because of the amount of unremunerative labour they devote to the State in the exercise of their profession. But in future we must not lay this flattering unction to our souls, for it seems that the real cause for exemption from jury service is to be found in the moral depravity which was supposed to be an indissoluble accompaniment of the surgeon's art. That some such feeling did actually exist seems beyond doubt, and the pre-anæsthetic operative surgeon must necessarily have been a man who could subordinate his natural feelings of mercy to the prosaic and sanguinary requirements of the moment, but if only for the sake of his own practice it is hardly likely that the surgeon of old days would have cultivated deliberate callousness.

"Dressed like a Medical Student."

HOWEVER, the pursuit of natural knowledge used generally to be credited with a tendency to make men irreligious, and that of medicine with making them both brutal and unmannerly. The great Dr. Arnold, of Rugby, who in his generation was accounted one of the most ardent reformers, and who possessed a more open mind than most of his contemporaries, strongly opposed the admission of medical students to Oxford because of the strong tendency of their presence and manners to debase undergraduates reading divinity and polite letters—an objection which was vigorously supported on all sides. It savours perhaps of unctuous rectitude to say, with the snail, that we have changed all that, but even if it is the fact, as we ourselves unhesitatingly believe, the old tradition dies hard. Any audacious lark or low street trick is the work of the medical student still in the eyes of mentors of the press. A more than usually amusing instance of this gratuitous assumption occurred in connection with the "Strand Baby" case last week. As most readers know, a young man and woman entered the West Strand Post Office one evening with a baby, and after some preliminaries despatched the infant to a lying-in hospital by messenger boy, and then decamped. As the incident furnished good copy, there was a tremendous clatter in the yellower organs of the press, and many puerile theories and clues were put forward to keep the public agog. One reporter had an "interview" with one of the Post Office clerks, on the strength of which he obtained details of the costume of the couple. The man wore a tweed suit and a large baggy cap such as is the fashion of the moment, being, in fact, said the account, dressed like a medical student. A medical student, then, on this conclusive evidence, must have done the dark deed. We did not know that there was anything particularly distinctive about the dress of medical students, and whatever there may have been in this particular instance was rendered nugatory by the event, for, when the man was found two or three days later, it turned out that he was a postman.

One Inspector, One Microbe.

THE recent proceedings of the new London County Council with regard to the milk-supply of the metropolis pass the wit of man to understand. In the first place, on taking office the Council withdrew from their Bill then before Parliament all the clauses giving them greater powers of inspection and supervision of the milk-trade; then a few months afterwards, recognising that this move was a mistake, they proceeded to refer the matter to the Public Health Committee with a view to obtaining such powers from Parliament. Last week, when the report of this Committee came up for discussion, they passed an amendment which amounted practically to a decision to do nothing beyond making representations to the Local Government Board about the unsatisfactory state of the milk-trade. By way of illustrating the practical knowledge possessed by the Council in the matter, one member got up and moved an amendment demanding that no milk should be sold in London except in glass-bottles, hermetically sealed, and having on them the name of the farmer and the stamp of an authorised inspector guaranteeing the purity of the contents. He pointed out that to be certain of the freedom of milk from contamination under any proposal, an army of inspectors would have to be employed all along the line, but according to his proposal the inspectors would only be needed at the source. We shudder to think what the price of milk would mount up to under such a system, and also at what hour in the day it would reach the consumer. A speaker who followed made play with this visionary proposal, and said that its chief virtue consisted in the amount of work it would provide for the unemployed. Indeed, it seemed to him to be a case of one inspector, one microbe. The amendment was lost on a division, it is true, but the ugly fact remains that the Council exhibit every symptom of being possessed with a desire to burke the main question, and there seems no way of getting them up to scratch and keeping them there.

The Doctor as Parson.

The Reverend H. Tracey, of St. Saviour's, Dartmouth, is, we gather from a recent article from his pen, one of those enlightened members of the clerical profession who see that the Church has a social, as well as a spiritual duty to the State, and that in its performance important help will be readily forthcoming from medical men. Mr. Tracey, it seems, has long liked to have doctors read the lessons in his church, but this passive use of their energies he would now like to see supplemented by the more active one of preaching. The late Dean Stanley frequently invited distinguished laymen to preach from the lectern in the Abbey, and Mr. Tracey advocates the extension of this principle to medical men. "To have expert testimony to the value of cleanliness, purity, sobriety, simplicity of living, the ease of extracting the greatest nutriment from the simplest and cheapest food, the beneficent effect of sunlight, fresh air, pure water, regular work, regular play, and similar topics would" he writes, "be of infinite value, and would 'save' the bodies of many who would then see how rational it was to 'save' their souls as well." There is, we believe, no reason why medical men should not be licensed to preach in churches, but we do not know of any instance in which any one of them is. That the advocacy of such principles as Mr. Tracey suggests would do more for people's lives than many of the platitudinous utterances that pass for sermons would hardly be denied by anyone conversant with the facts.

Death of Sir William Broadbent.

The death of Sir William Broadbent removes from the medical world a big figure, for although to the public Sir William was known chiefly as a Court physician, by his colleagues he was respected as a particularly sound and accomplished physician. He had formed his views not on intuitions and ideas, but on the broad basis of accurate clinical study, and they were therefore not only firmly held, but well-grounded in commonsense. He knew his own mind and spoke it with Yorkshire-like directness, but he was generally right and invariably high-minded. His promotion to Court circles at the time of the Prince of Wales's illness was something of a surprise when it occurred, as he had not trodden in the Jennerian footsteps, but not only did his skill soon recommend him to the friends of his Royal patient, but, we believe, the King and Queen entertained a very high regard for him both personally and professionally. Sir William Broadbent had many of the qualities that make a leader of men, and he would have been sure of success in almost any line of life, but it is as a leader of good causes in the profession that he will be most immediately and truly missed.

LEADING ARTICLES.

THE GENERAL MEDICAL COUNCIL AND THE DENTAL COMPANIES' BILL.

The General Medical Council is the only body to which we can turn hopefully as the active instigator and framer of legislation calculated to protect professional interests. Undoubtedly the great want of medical practitioners at the present moment is an Act that will put an effectual stop to the unlawful practice of medicine for gain and the sale of quack medicines. By satisfying that demand Government would also be taking a step of unmeasurable importance towards the better safeguard of the welfare of the public.

The legislature that draws up stringent medical Acts providing for the efficient education and legal qualification of medical practitioners recognises the absolute need of careful special training for the practice of medicine. If the same legislature permit quacks and charlatans to perform medical functions, then it nullifies its former position, assumes the right of any man to practice medicine at his own free will, and practically says that the public does not require to be protected against irregular practices. The State, in other words, declares that a thing can both be and not be: that the man in the street requires to be protected against ignorant medical men, but not against ignorant quacks. Yet the Government of this country is not without some saving grace, so far as the attempt to keep in touch with medical aims, ideals and aspirations is concerned. The General Medical Council occupies an advisory position of great weight by virtue of its connection with the Privy Council. The opinion of the great so-called governing body of the profession is sought upon medical questions that may come under the consideration of the legislature. It is always of interest, therefore, to ascertain as far as possible, in what directions that influence has been brought to bear. The interests of the dental profession are in charge of the General Medical Council. They are professedly involved in the Bill now before Parliament to restrict the practice of dentistry by private or public companies.

The General Medical Council has promoted the Bill known as the Dental Companies' (Restriction of Practice) Bill. The opinion of the dental profession with regard to the Council's championship of their rights may be gathered from a leading article in the *British Dental Journal* for July 1st, 1907. "We wish to speak in terms of moderation," it says, "but desire at the same time to rouse the dentists of the country to a sense of the injustice and injury which that Bill will inflict upon them and the people should it unfortunately pass. . . . The Bill is careful enough to provide for something which never has occurred and never is likely to occur, viz., the formation of a company to carry on dental practice by means of qualified men ; and careless enough to legalise by a few ill-considered words the practice of dentistry in one of its most important branches by unregistered men. There can be no doubt that if this clause stands, hundreds of qualified dentists who have spent much time, money, and exertion in obtaining a registrable diploma will be ruined." These strong words, coming from a responsible and authoritative source, can hardly fail to engage the earnest consideration of the General Medical Council. If it be the serious intention of the Government to defend the interests alike of the qualified dentists and of the public by fresh legislation, then it is evident the present Bill will have to be recast. But the attitude of the General Medical Council has an important bearing upon the interests of medical practitioners who find themselves hampered by competition with companies formed to carry on all sorts of medical treatment, and to sell all kinds of nostrums claiming to cure all sorts of ailments. Will the General Medical Council be able to frame a better Bill for the protection of medical men than it has for dental surgeons ? Precisely identical principles are involved in both cases, and just the same zealous sympathy, informed wisdom and resolute determination are demanded in the one instance as in the other. The present position appears to emphasise the inherent weakness of the Council in its virtually non-representative constitution. In conclusion the following passage from the *British Dental Journal* may be quoted :—" We are by this Bill most shamefully entreated. We have for long been used to being ignored, flouted and misunderstood by the Medical Council, and in spite of it all we have displayed to that body a passionate loyalty that in the light of this Bill is truly pathetic. The memorandum states that the Bill has the support of the General Medical Council ! We are indeed wounded in the house of our friends."

CURRENT TOPICS.

For London or for the United Kingdom ?

WHEN the Royal Society of Medicine was constituted we looked forward with special pleasure to its probable effect upon the Obstetrical and Gynæcological Societies. We expected that nothing but good could come from such a union, that the Obstetrical Society would gain very materially by the broadening of its views consequent on the influx of new members, and that the Gynæcological Society would also profit by acquiring an equal share in the prestige of the older Society. No one could doubt that both consequences were very much to be desired. The Obstetrical Society had always something in its atmosphere which seemed to stifle those who would have levelled up London obstetrics and gynæcology. The Gynæcological Society lacked the prestige of age and associations which one naturally looks for in the case of an important institution. It is therefore with very keen regret, and we confess with not very hopeful forebodings, that we have read the list of " officers recommended by the Council " for election at a Special General Meeting to be held in October. It is at once apparent from this list that so far from this particular section of the Royal Society of Medicine being one which will seek to attract to its ranks prominent obstetricians and gynæcologists from all parts of the United Kingdom, it is to be again a mere repetition of the Obstetrical Society. For the new Council there have been nominated, by the existing Council, twenty-nine members from London, six members from the English provinces, one member from Scotland, and not even a single Irish representative. Now, Scotland is very well able to look after its own interests, and therefore we shall not comment on the curious manner in which its specialists have been welcomed to the ranks of the new section. We turn now to the case of Ireland. We believe we are correct in saying that in the list of past and present officers of the British Gynæcological Society there are the names of at least two Irish ex-presidents, and at least three Irish ex-vice-presidents, not to speak of others who have been members of the Council. We believe we are also correct in stating that these gentlemen were invited to join, and did join, the new section, together with other Dublin obstetricians and gynæcologists who were members of the Gynæcological Society. Yet of them not a single one has been considered by the existing Council to be worthy of a place on the new Council. When policy, civility, and ordinary fairness unite to point out a certain course of action there must be a very definite reason why the course is not followed. What that reason is time will show. We trust it is not due to a desire to maintain the traditions of the Obstetrical Society.

Instruction for Mothers.

WE are glad to learn that some recent ventures in the Metropolis directed toward the instruction of mothers are progressing satisfactorily. For some years, in Paris, Brussels, Ghent, and other continental cities, centres have been established where mothers could obtain proper advice as to the care and feeding of young children. More recently the Marylebone Health Society and the St. Pancras Mothers' and Infants' Society entered on similar work in their respective districts of London. Mothers and expectant mothers are taught how to wash, clothe, feed, and generally tend young infants, and the importance of natural feeding is emphasised. In cases where artificial feeding is necessary, the mother is given instructions on the preparation of the most suitable foods. It is claimed that the result in the shape of healthy, well-nourished children is most gratifying, and we can well believe it. It is a commonplace that the greater part of infant mortality is due to ignorance rather than carelessness or crime, and any effort to dissipate this ignorance deserves the hearty support, not only of the medical profession, but of all interested in the welfare of the race.

The Adequacy of Fines.

THE necessity of enforcing high standards of purity in food and drugs has been recognised in many Acts. There are many ways, however, in which the intention of the legislature may be frustrated. In some cases the machinery of the local authorities for the collection and testing of samples is defective. In others the limit of the penalty that may be imposed is too small to be of any real deterrent effect upon offenders, or magistrates may be too lenient in the matter of fines. It is notorious that certain fraudulent milk-sellers find it a paying business to go on selling adulterated milk and to charge against profits the fines that are constantly imposed upon them. In the matter of meat and tinned goods magistrates, as a rule, are inclined to impose full penalties. Last week a penalty of £50 and £2 2s. costs was imposed upon the keeper of some stores in Camberwell for exposing for sale tinned and bottled goods unfit for human consumption. Were all fines for this class of offence fixed on a similar scale of adequacy, the safety of the public would be proportionately increased. In a matter of this kind, above all others, it is desirable to have some sort of concerted action amongst the magistracy in their administration of the law.

A Year's Trade Accidents.

THE Annual Report of the Chief Inspector of Factories and Workshops for the year 1906 was issued, on the 10th inst., in the form of a Parliamentary paper. The document registers a great advance in the condition of industrial labour. At the end of the year there were 109,065 factories and 146,124 workshops upon the registers. The number of persons employed in factories is about 4,150,000, in workshops 700,000, and in laundries 100,000. The total number of accidents reported in the year 1906 reached the great number of 111,904, of which 1,116 proved fatal. These figures show an increase of 11,295 accidents, or 11·2 per cent. as against the preceding year; while the fatalities are greater by 53 or 5 per cent. It is interesting to note that the greatest number of fatal accidents, namely, 149, occurred in the making of machines, engines, &c., while 145 occurred in the construction of buildings, and 143 in docks. The cases of industrial poisoning totalled 707, of which 54 ended fatally. Only one case of phosphorus poisoning was reported. Attention is called to the coming into force of the Workmen's Compensation Act, 1906, which it is pointed out, broadens the scope of the earlier Acts, and in particular extends compensation to certain scheduled industrial diseases. In view of the importance of the new Act, the attention of medical practitioners may be drawn to this important Parliamentary paper.

Medical Practice by Companies.

PARLIAMENTARY proceedings with regard to medical practice by companies are of vital importance to the medical profession. Some weighty evidence has been laid before the Lords by the chairman of the London and Counties Protection Society and the Secretary of the Medical Defence Union. Dr. G. Heron pointed out forcibly that the limitation of the scope of the proposed Bill to joint stock companies would render it almost valueless, as the majority of such companies were of a non-joint stock nature. Dr. A. G. Bateman went to the root of the matter when asked whether he had any suggestion or amendments in connection with the Bill. "I am afraid," he replied, "that the only amendment we should like would be a complete alteration of title and a complete alteration of the clauses, so as to put a stop to medical practice for gain by persons who are not qualified." That is the bed-rock of the question. The legislature is asked to stop medical practice by companies who collectively perform acts that individually performed would be illegal. If the safety of the public demands that unqualified practice of medicine by companies be abolished, why not also that of individuals? The view so clearly and courageously advanced by Dr. Bateman would come naturally and gracefully from the General Medical Council.

Ingenious Milkmen.

A CERTAIN class of milk vendors exercise a fiendish ingenuity in devising methods for adding to their legitimate income a profit obtained by fraud. It is, of course, highly important (to the offender) that the method adopted should not bring him within reach of the law, and hence, while he courteously supplies the stranger with a genuine article, his long-suffering regular customers do not obtain milk "of the nature, substance, and quality demanded." The procedure of some sinners within the Borough of Portsmouth in the sophistication of their milk is mentioned by the Public Analyst, Mr. F. W. Arnaud, in his annual report. The milk vendor carries two churns on his cart, one containing skim, and the other whole milk. The former churn is duly labelled "separated milk," but the label is stuck so near the base of the churn as to pass unobserved by anyone not standing immediately over the cart. Customers are served from a small can, which never contains much more than is required by the next customer. For regular customers a special mixture from the two churns is supplied, while a suspicious-looking stranger is supplied from the churn containing genuine milk. If necessary, the milkman obligingly points out the label "separated milk" to the inspector. When it is remembered that an average genuine milk can be diluted with 30 per cent. of separated milk without bringing the fat below the 3 per cent. standard, it will be seen that the vendor will not be liable to prosecution if the small can contains a little of the "regular customer's mixture," when the genuine article is run in for the inspector. Mr. Arnaud suggests the necessity for a new Act rendering it illegal to carry both whole and separated milks on the same cart. Meanwhile, the inspector is baffled, and the offender grows rich at the expense of the consumer.

PERSONAL.

On July 13th, Degree Day at Liverpool University, the following honorary degrees were conferred :—Professor F. Gotch, D.Sc.; Professor W. Osler, D.Sc.

The Court of Governors at Guy's Hospital sanctioned the formation of an orthopædic department, and appointed Mr. R. P. Rowlands, M.S., as surgeon to the hospital in charge.

Lady Broadbent on July 11th received the following telegram from Sir Arthur Bigge :—"The Prince and Princess of Wales are grieved to hear of the irreparable loss which you have sustained, and desire me to assure you and your family of their true sympathy in your sorrow."

Lieutenant-Colonel Sir J. Fayrer, medical officer of the Duke of York's School, has been appointed to the medical charge of the Union Jack Club.

Sir Alfred Jones, K.C.M.G., the president of the Liverpool School of Tropical Medicine, has received a grateful letter of thanks from the President of the Republic of Peru, acknowledging copies of a report in Spanish on the "Health of Iquitos," by Dr. H. Wolferstan Thomas, member of the yellow fever expedition of the school.

On July 11th the members of the Birmingham Medical Benevolent Society presented an address and a handsome service of silver plate to Mr. W. F. Haslam, who recently retired from the post of honorary secretary to the society, after sixteen years' service.

Dr. J. Ll. Williams, of Wrexham, has been appointed medical referee under the Workmen's Compensation Act, 1906, for the County Court districts of Corwen and Bala and Wrexham and Llangollen.

Dr. Robert Barnes, whose death, at the age of 89, was recently referred to in these columns, has left estate valued at £183,074 gross, with net personality £175,176. He left £500 each to St. George's Hospital and St. George's Hospital School, London; the Medical Benevolent College, the Dreadnought Seamen's Hospital, and St. Thomas's Hospital; £300 to the Royal Maternity Charity; and £200 each to the School of the London Hospital and the Princess Alice Memorial Hospital, Eastbourne.

Dr. G. G. Shattock has been appointed to deliver one Erasmus Wilson lecture on Ovarian Teratoma, and Dr. J. W. H. Eyre, M.S., Dub., and Mr. Leonard S. Dudgeon, lectures on other subjects.

Mr. James Taylor, F.R.C.S., has been made the recipient of a handsome testimonial on his retirement after forty years' service on the surgical staff of the Chester Infirmary.

Dr. George W. Crowe, of Worcester, was entertained at dinner and presented with a piece of plate by his fellow-members of the Worcestershire and Herefordshire Branch of the British Medical Association at the end of last month.

Lady Duckworth-King is to open the recently-erected electrical department of the Royal Devon and Exeter Hospital, presented by Mrs. Sanders, on Friday next.

Mr. Hudson E. Kearley, M.P., will distribute the prizes to the students and nurses of the London Hospital this afternoon at 3.30 in the library of the Medical College.

The prize distribution at St. Mary's Hospital, which was to have taken place on July 11th, has been indefinitely postponed in consequence of the death of Sir William Broadbent.

Dr. C. E. Underhill presided over a luncheon on July 6th given by the Royal College of Physicians of Edinburgh to the medical officers of the Channel Fleet.

Dr. W. F. Surveyor has been appointed to the chair, of bacteriology at the Grant Medical College, Bombay.

The Duke and Duchess Karl Theodor of Bavaria have just arrived in this country. For many years the Duke has performed operations for cataract, the total of which has already exceeded 5,000. He is assisted in his work by the Duchess.

The Science Committee of the British Medical Association has adjudicated the Middlemore Prize to Mr. Sydney Stephenson, for the outstanding merit of his essay upon Ophthalmia Neonatorum. This prize is awarded every three years for an ophthalmic subject.

Mr. Henry Morris has been re-elected President of the Royal College of Surgeons of England.

Mr. Watson Cheyne, C.B., F.R.S., and Mr. Rickman Godlee, F.R.C.S., have been elected vice-presidents of the College of Surgeons of England for the ensuing collegiate year.

Mr. W. S. Handley, M.S.London, has been appointed Hunterian lecturer for one lecture on the Therapeutic Criteria of Cancer, and Dr. V. Bonney, M.S.London., for three lectures on the Connective Tissues in Carcinoma. Mr. B. Armour, M.B.Toronto, Mr. A. R. Thompson, M.B.Vict., and Dr. F. C. Shrubsall, are to give other lectures.

Dr. F. A. Bainbridge, M.A.Camb., has been appointed Arris and Gale Lecturer, to give one lecture on the Pathology of Acid Intoxication, and Mr. Major Greenwood, junr., two lectures on the Physiological and Pathological Effects which follow Exposure to Compressed Air.

A portrait of Dr. John Beddoe, F.R.S., has been formally presented to the City of Bristol by the Right Hon. Lewis Fry.

In our "Births, Marriages and Deaths" column today are two announcements which read side by side appear almost tragic. On the 9th inst., the son of Mr. Samuel Benham, M.R.C.S., of Hampstead was married; the next day the sudden death of the father occurred.

A Clinical Lecture

ON

THE TREATMENT OF CARCINOMA OF THE GREAT INTESTINE. (a)

By SETON PRINGLE, M.B., B.Ch. (Univ. Dub.), F.R.C.S.I.,
Surgeon to Mercer's Hospital, Dublin.

Gentlemen.—The subject about what I wish to speak to you this morning is the treatment of carcinoma of the great intestine exclusive of the rectum. The great intestine, as you know, is a common site for malignant disease, and it is gratifying to be able to state that the treatment of this condition by *early* operation is attended by success in a great number of cases. You note that I lay emphasis on the word *early*, for unfortunately we generally get these cases, at least in hospital practice, only when the disease is far advanced and one or other complication has set in, therefore I want to impress on your minds the importance of making a full and careful examination of every elderly patient coming to you complaining of vague abdominal symptoms such as colicy pain, constipation, diarrhœa, or the passage of mucous, blood or pus in the motions. I believe that at present we do not attach nearly enough importance to the microscopical and chemical examination of the fæces in abdominal cases. You all know how much can be learned from careful examination of the urine, sputum, or gastric contents in diseases of the kidneys, lungs or stomach, and yet in how very few cases of intestinal disease do the fæces receive similar attention? Professor Nothnagel states that in only two conditions are pus, mucus and blood persistently found together in the stools. These two conditions are carcinoma of the great intestine and dysenteric ulceration. The latter disease is usually easily diagnosed, and therefore the discovery of these three abnormal constituents of the fæces would be of the greatest assistance in arriving at the diagnosis of cancer in cases presenting symptoms of intestinal stenosis, but in which no tumour could be felt. Leaving fæcal impaction out of the question, the presence of a palpable tumour in an elderly person with symptoms of complete or partial intestinal obstruction, of course practically settles the diagnosis of cancer, but as in many cases the growth is situated at an inaccessible part of the intestine, such as the splenic flexure, or is too small to be felt, the importance of the knowledge gained by examination of the fæces cannot be over-estimated.

The cases of cancer of the great intestine, which present themselves for treatment, may be divided into two main groups, namely, cases which are not and cases which are suffering from acute intestinal obstruction at the time of examination, and the latter are at least, in my experience, by far the more numerous.

First then as regards the treatment of the cases coming into the former class. As soon as the diagnosis is made, and except the disease is very far advanced and the patient evidently rapidly on the down grade, it is certainly the surgeon's duty to advise immediate laparotomy, and then to be guided in the course he pursues by the conditions found in the abdominal cavity. If the tumour be movable and the lymphatic glands be either apparently normal or enlarged only in the vicinity of the growth, the affected part of the intestine, and at least two inches of normal gut on either side, should be excised. (It is not my intention this morning to describe in detail any of the operations I may advocate, but merely to outline them in a few words). Along with the tumour we must remove either a wedge-shaped piece of the mesentery or, if the intestine at the situation has no mesentery, then as much of the fatty bed on which the bowel rests as can be taken away without endangering the blood supply of the normal gut. In either case our endeavour is to remove in one piece with the growth the lymph channels and glands draining the part. When the growth has been cut away, an end to end anastomosis by suture should be performed in those parts of the intestine which are almost completely surrounded by peritoneum. In other parts, such as the ascending or descending colon the divided ends of the bowel should be closed and a lateral approximation carried out. In the case of the cæcum, where the ileocæcal valve has been removed, it is well to close the lower end of the ascending colon and implant the cut end of the ileum into the lateral aspect of the colon, preferably incising the latter in the line of one of the longtitudinal muscle bands. Frequently we find on exploring the abdomen in these cases that although the patient has not suffered from acute intestinal obstruction, yet a chronic condition of obstruction is present, and here the gut above the stricture will be distended, often enormously so, and the mucous membrane ulcerated, while the intestine below will be contracted. In these cases it is necessary to perform a lateral anastomosis, or sometimes even a temporary colostomy to allow of the distended upper segment of bowel regaining its healthy condition before proceeding to excision of the growth at a later sitting. Of course if another portion of the intestine or the omentum is found adherent to the growth the adherent structure must be removed in one piece with the growth itself. Occasionally in this first class of case we find a growth which is obviously irremovable, and then I consider it is best to perform a lateral anastomosis between the afferent and efferent loops of bowel so as to short circuit the current of intestinal contents, and thus obviate either the occurrence at a later date of acute obstruction or the formation of an artificial anus above the site of the tumour. This operation is comparable to that of gastro-enterostomy for inoperable carcinoma of the stomach involving the pylorus, and even if it is not attended with such obviously beneficial results to the patient, surely it is preferable to the establishment of a permanent colostomy? In this connection I may mention that anastomosis of the transverse to the pelvic colon has been frequently successfully carried out for irremovable growth of the splenic flexure or descending colon.

(a) Being a Lecture delivered at Mercer's Hospital on April 10th, 1907.

The consideration of the treatment of the second group of cases, viz., those in which acute intestinal obstruction is present as a complication of the malignant stricture, is more interesting, as here we have to note the very marked advance of surgical procedure and technique of comparatively late years. Formerly in these cases it was the recognised practice to, if at all possible, excise the growth and perform an immediate end to end anastomosis; but this line of treatment was found to be attended with a mortality of something like fifty per cent. This result is just what might be expected, if you consider the condition of the intestine in an acute obstruction. The gut above the stricture is enormously distended with decomposing fæcal material and gas, the mucous membrane is ulcerated and the wall in its entire thickness inflamed. How then could we expect to obtain satisfactory union at the line of suture? Is it not evident that the sooner the toxic products of decomposition be allowed to escape the better the patient's chance of recovery? Remember that in the great majority of cases of acute intestinal obstruction the patient is killed by toxæmia and not by any local condition. It is therefore now recognised that the important part of the operative treatment of acute obstruction from growth is the immediate provision of a free outlet for the toxic intestinal contents which relieves the patient's toxæmia and allows the gut to regain its tone and normal structure. It is not justifiable to undertake a prolonged operation with the object of immediate removal of the tumour and restoration of the continuity of the bowel, since the result can be much more safely obtained by carrying out the operative treatment in two or three stages. The number of separate operations is determined by the possibility or impossibility of delivering the growth out of the abdominal cavity. In the first class—*i.e.*, when the growth can be so delivered, the best procedure is to lift the involved loop of intestine out on to the abdominal wall and then, after suturing the parietal peritoneum around the two limbs of the loop, to excise the tumour with a wedge-shaped piece of the mesentery, and tie a large Paul's tube into either cut end of the gut to permit of the free escape of the intestinal contents. If at the same time we stitch together the mesenteric borders of the afferent and efferent limbs of the loop of bowel, then, after some weeks elapse, the spur between the two segments can be safely destroyed by an enterotome, and the artificial anus can be closed, as Paul himself says, "by separating the rosette of mucous membrane from the skin, turning it in and bringing the freshened edges of the latter over it." If the mesenteric borders are not sutured together, then the second and final stage of the operation consists in closing the artificial anus in the usual way.

On the other hand, if we find at the primary operation that the tumour cannot be delivered out of the abdominal cavity, it is best to perform a colostomy above the site of the growth, to relieve the urgent symptoms of obstruction; and then, some weeks later, the abdomen is again opened over the position of the tumour which is excised, and an end to end or lateral anastomosis carried out. In such a case the third or final stage consists in closing the colostomy by a suitable operation. If considered advisable the colostomy can be closed at the same sitting in which the tumour is excised; but personally I consider it is wiser to carry out the treatment in three stages, as we are much more certain of getting satisfactory union at the line of anastomosis if no fæcal material travels over it for a few days.

Within the last few months you have had an opportunity of seeing three cases of carcinoma of the great intestine under my care. All three came into hospital in a condition of acute obstruction.

The first case was that of a man, æt. 65, who some six months previously had been admitted under my care. On that occasion he complained of colicky abdominal pain for the twenty-four hours before admission; he had also vomited several times, and there had been no movement of the bowels; but as he was habitually constipated he attached no importance to the latter fact. His general condition was very good and abdominal distension not a marked feature. I ordered him a large enema, and remained in the hospital to learn the result. The injection brought away a large motion and all his symptoms subsided; therefore, as on careful examination no tumour could be felt in any part of the abdomen, I was inclined at the time to consider his condition as due to fæcal impaction. He was consequently discharged from the hospital in a few days, and remained well except for the troublesome constipation, till he was admitted the second time, six months later, with acute intestinal obstruction. I immediately operated and performed a cæcostomy, but unfortunately he gradually sank and died a fortnight later. At the *post-mortem* a tight malignant stricture at the splenic flexure was found.

The second patient was a woman, æt. 60, who had suffered from constipation for some time, but otherwise had enjoyed very good health till some thirty hours before admission, when acute obstruction suddenly set in. In her case the growth was situated in the lower end of the pelvic colon, and again colostomy was performed immediately, but failed to save her life.

The third case furnishes a good example of the "three stage" operation, and I will therefore enter into more detail in recalling it to your memories. The patient, a labourer, æt. 60, was admitted late one night some months ago, and then gave the following history:—For some years he had been more or less constipated, and for the three weeks preceding admission he had been unable to obtain a satisfactory movement of the bowels, although the very day before coming here he had passed a small motion. After this motion severe colicky pains commenced in the abdomen, and these pains persisted up to the time of admission twenty-four hours later. During the same period he had also vomited frequently. I saw him an hour after his arrival, and found the abdomen greatly distended, while by both palpation and percussion the cæcum and entire length of the colon down to the pelvic brim could be easily demonstrated to be in a very dilated condition. From this it was evident that the obstruction was either situated in the pelvic colon or rectum. I then passed a finger up the rectum and was just able to feel that there was a tumour in the pelvis lying slightly to the left of the middle line. I could not feel the tumour directly, but there seemed to be several thicknesses of gut between the examining finger and the mass. By this time the colicky pains had ceased, no doubt because the intestine was passing into a condition of paralysis or ileus. The diagnosis of cancer of the colon, situated probably about the junction of the pelvic colon and rectum, was easily made, and I had the patient at once prepared for the operation. It is always a wise precaution in these cases to have the stomach washed out preparatory to anæsthesia, as it lessens the risk of the patient developing an inspiration pneumonia should he vomit during the administration. At the operation I opened the abdomen in the left inguinal region by the muscle splitting method, and on passing my hand down into the pelvis I easily found the growth, but was unable to draw it up out of the wound; and consequently I performed a colostomy in the following manner:—I passed as much of the pelvic colon as possible down into the pelvis, so that if I came to attempt excision of the tumour afterwards, the tumour would not be fixed, and thus increase the difficulty of the manipulation. This procedure of selecting as high a part of the bowel as possible for the colostomy also obviates to a great extent the occurrence of prolapse through the artificial opening. I then sutured the parietal peritoneum round an oval area on the free aspect of the selected piece of colon, and finally inserted a large Paul's tube in the centre of the area thus shut off from the general peritoneal cavity. During the next twelve hours some four and a half gallons of fluid fæces escaped through the tube. The patient reacted well, and his general condition improved so much that I decided to, if possible, remove the growth. Consequently, three weeks after the first operation I opened his abdomen in the mid line above the pubis after temporarily sewing over the colostomy to prevent soiling. On passing in my hand I was able to grasp the tumour and draw it up till it was between the lips of the wound in the parietes. I then divided the gut on either side of the tumour between clamps and quickly did an end to end anastomosis by suture; fortunately I was just able to leave enough of the gut below the growth completely covered with peritoneum to allow of this method to be carried out with safety. Again he made a good recovery, and finally some weeks later I successfully closed the colostomy.

These three cases exemplify, at least, one very important point. In all of them we see the insidious manner in which the disease may progress, so very insidious indeed that in two of them the onset of acute obstruction was the first symptom which caused them to consult a medical man. In all, indeed, we find a history of constipation for some time, but this is a very common complaint in old people, and too much stress must not be laid on it. In only one an attack of colicy pain preceded the obstruction by several months, while from none of them could we obtain a history of the alternating attacks of diarrhœa and constipation described as typical of intestinal stenosis. In the third case a gratifying result followed the employment of the "three stage" method of operating, and we may be reasonably certain that had a radical removal of the growth with immediate end to end anastomosis been attempted in the first instance the case would have had a rapidly fatal termination, considering the condition of the bowel at the time of the first operation.

In conclusion, therefore, gentlemen, let me again remind you (1) of the great importance of making a full and painstaking examination of all patients past middle life who complain of any abdominal symptoms at all referable to narrowing of the lumen of the bowel, for only by early diagnosis of these cases can the results of treatment be improved, and (2) of the necessity to provide an immediate means of escape for the toxic intestinal contents in all cases of acute obstruction.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Purves Stewart, M.D., F.R.C.P. Lond., Physician to Westminster Hospital and to the Royal National Orthopædic Hospital. Subject: "Disorders of Sleep."*

ORIGINAL PAPERS.

THE GENERAL PRACTITIONER.

II.—HIS CLAIM TO RECOGNITION.

By J. LIONEL TAYLER, M.R.C.S., L.R.C.P. LOND.

I PARTICULARLY do not wish to claim more than what is obviously the general practitioner's due, but it seems to me there are three aspects that are particularly his own—(1) as an expert in the beginnings of disease; (2) as an expert in common diseases which the consultant and hospital practitioners seldom see; (3) he is the only first-hand observer in the influence of environment on healthy and diseased individuals.

(1) *An Expert in the Beginnings of Disease.*—It is unquestionable that the majority of patients are seen in the first stage of their illnesses by the general practitioner. It may, however, be argued that, in proportion to the much smaller number of specialists, their experience is nearly as large, though I think few would venture to assert this. Were it so, however, it would still be true that the ordinary medical man is in this respect at least as entitled to speak and write authoritatively on this aspect of medicine as the consultant.

As a student, I remember the scarcely-veiled contempt that the young house physician or surgeon and occasionally the senior staff displayed for the general practitioner's skill, and to me the feeling at the time seemed wholly justified. Cases of appendicitis sent in too late; obvious abscesses that were pointing and had been unopened; advanced cases of phthisis undiagnosed; tumours not discovered that were almost visible to the naked eye, and other like conditions passed over apparently ignorantly or carelessly.

When, however, I went into practice myself I learnt otherwise. I was informed by a colleague that text-book and hospital information would help me little. I asked why? He said he did not know, but cases in hospital seemed to be different from those outside. And his conclusion I was soon able to verify.

In fevers, where it is necessary to distinguish the notifiable from the unnotifiable diseases, and the slight cases of febricula from the more defined infections and from the beginnings of tubercular disorders, I discovered that these early symptoms, which are of common every-day occurrence, are scarcely alluded to in our text-books. I accordingly wrote to the superintendent of one of the large fever hospitals, where I had been trained, stating my difficulty, and asked if he could recommend me a work that gave more attention to this subject. In his reply, while regretting that he was unable to suggest any book that would be valuable, but thinking of one the kind needed, he writes that the fever hospital physicians get their cases "a little later than the certifying general practitioner and so have to deal with a more developed disease." It is this conclusion that I had myself reached which is characteristic of the whole aspect of the ordinary medical man's practice. *He sees every disease a little or a great deal earlier than the specialist.*

In no acute disease, if the onset is sudden, does the hospital physician or surgeon see the case before the local one, for the patient either is in bed or goes there as soon as grave symptoms appear. Where the disease is less acute a few cases are sometimes seen at the hospital drawn from its local surroundings, but these are necessarily small in number, and as they are distributed over many wards and are first seen by students and transient resident medical officers they make too small an impression on the general class of patient to affect the visiting physician or surgeon, and it is he who writes on medical subjects. In acute disorders, therefore, the general practitioner sees the patient before any other professional man, and since he has to make some sort of diagnosis in order to tell how to describe the illness and determine where to send the case to, it is evident that this field is his alone and yet it is unrepresented by him in medical literature.

In chronic disorders this is, perhaps, less true, but even in these the family practitioner is usually first consulted and later, with or without his advice, a specialist is seen.

This, then, is partly why the young student is so unfavourably impressed with the outside medical man. Hospital cases are nearly always in a more developed condition, and hence are more readily diagnosed than when they are first seen. In the interest of medical science this aspect requires more detailed treatment than it has yet received, but until such a province is recognised as belonging to the general practitioner there is little hope of improvement.

(2) *An Expert in the Commoner Diseases.*—These, though less characteristic, are still a distinctive element in general practice, and what are alluded to as "slight ailments" have been, and are still, quite exclusively within this field and are scientifically perhaps the most important group of diseases to study. These slighter maladies shade almost imperceptibly into the beginnings of the more serious diseases, and where this is not so they prepare for them by weakening the resistance of the patient. The relation of repeated "colds" to tuberculosis in some form is close both in children and adults, and the gradual passage of "eccentricities" into recognised forms of insanity has never, as a subject of research, received even a small part of the attention it deserves. If the ordinary medical man were encouraged to study his cases more carefully and scientifically there can be no doubt whatever that all members of the profession would gain in knowledge as a result.

In the more pronounced illnesses such as bronchitis, consumption, nephritis, alcoholic and dyspeptic states, the experience of the general practitioner, though, of course, much inferior to the true specialist on his own line, is from a different point of view as worthy of consideration as that of the general consultant, for if he has less time to study the case at the moment of consultation he has yet followed the development of the disease in his patient for a much longer period, and he is often well acquainted with the family history and the circumstances that may have contributed to its onset. In such cases, therefore, the family medical man's opinion should receive more attention than is usually given to it, and if it is less valuable than it ought to be, this is largely due to the fact that it is so often disregarded and is consequently carelessly formed.

(3) *Environmental Influence on the Healthy and Unhealthy.*—The admission to the home of his patients, the gradual increase of friendly relations between them and himself, gives the general practitioner opportunities for research into problems of heredity, health and environmental influence that are absolutely unrivalled. He sees a patient, perhaps a young girl or boy, knows something of the parents, and sees afterwards this same patient when recovery has taken place in a few years, married and a parent. He can then trace with his own eyes influences through three, and in some cases, four generations, and he has not, therefore, entirely to rely upon mere spoken evidence, which is so often misleading. To see people under the various educational, vocational, and marital tests of life reacting differently according to different constitutions; to note differences of weather influences; the effect of poverty or of wealth, these, and a hundred other opportunities, are all before him. And it is mainly because he has not been encouraged to express his opinion that the average doctor fails to give satisfaction to his patients on many questions that they legitimately inquire about and with which our literature deals so slightly.

One may then sum up the position as follows:—The general practitioner is no longer a mere subordinate, but has his own particular sphere of investigation, due to his experience of the earliest stages of all diseases, and his exclusive study of disorders of a mild character. To this his information on hereditary endowment, personal habits, and environmental conditions must be added. It is upon such aspects of the health problem that his judgment should be sought, not only by the public, but also by other medical men (*a*), and this place in medical literature ought to be reserved for him.

It may be argued that these differences of experience should have been preceded by differences in early training. With this question I am not at present concerned, but I simply point out that whether he should or should not have been educated differently as he has in practice

---

(*a*) **I have, I hope, made it quite clear that the positions of the specialist and general consultant remain unaffected by the arguments. My claims being that there are certain *distinctive* features of general practice, which, for the benefit of the medical profession *as a whole* should be better recognised.**

a different, *not an inferior*, position to the consultant and specialist it is imperative that this difference should be recognised.

A NOTE ON

FRIEDREICH'S ATAXIA AND SYPHILIS.

By GEORGE PERNET,

Assistant to the Skin Department, University College Hospital, London.

In connection with Dr. F. S. Palmer's excellent clinical lecture, which appeared in The Medical Press and Circular for May 8, 1907, I should like to be allowed to make a few remarks from the point of view of prophylaxis.

Dr. Palmer states that evidence of syphilitic transmission has been rarely traced, and adds that there are few facts recorded to support the connection. As regards the syphilis factor, I should like to call attention to the four cases recorded by A. Bayet, of Brussels, as they appear to me to be important. (1) Shortly the details are as follows. The father stated he had never had a venereal complaint. That does not go for much, histories being so fallacious. Nor had he any discoverable morbid nerve condition. The mother, æt. 44, impressionable, no definite nerve complaint. In her first marriage: two pregnancies, the first being cut short by a miscarriage; the second ending in a female child, still living. As to her second marriage: four children, the subject of Dr. Bayet's communication:

A. A boy, æt. 17.
B. A girl, æt. 14.
C. A girl, æt. 11.
D. A boy, æt. 9.
E. A girl, twin-sister, of D., but she died of convulsions.

Above followed by five miscarriages.

An examination of the father and mother did not reveal any sign or symptom of syphilis. But I should like to insist in passing on the miscarriage in the first pregnancy (first husband). One miscarriage does not make syphilis, any more than one swallow makes a summer, yet it is a fact to bear in mind. As to the five subsequent miscarriages, they do not necessarily mean syphilis; on the contrary, for in syphilis it is the rule for miscarriages to occur in the earlier stages of the disease in the mother. Although the mother exhibited in herself no signs of syphilis, that does not exclude the possibility of the infection. But when we turn to the children we find evidence of syphilis in them. In all of them there were numerous scars all over the body, apparently the result of old ulcerating lesions. In all of them again there were radiating scars at the angles of the mouth. Moreover, in B. and D. there was diffuse opacity about the cornea, and in both these patients there were ulcerating gummata, of the tonsil in B. and of the foot in D. These gummatous lesions rapidly improved on iodide of potassium. In D. there was mapped tongue, which Bayet considers is a condition that may be connected with congenital syphilis, though not constantly so. I may add here that I have frequently seen mapped tongue quite apart from syphilis; nor do I consider it has any significance in that direction.

It is not necessary to go into the details of symptoms pointing to the family disease known as Friedreich's Ataxia, but suffice it to say that A. was most affected, next in order being C., and D.; B. exhibiting but slight signs, which became significant, however, when taken with the other three children's condition. The details can be read at large in Bayet's paper. On the face of it, the probabilities are that syphilis played an important part in the production of the Friedreich symptoms, not that I desire to make out that syphilis is always responsible for that disease; possibly a variety of infections and toxæmias may lead up to it. *Primâ facie*, the mother had had syphilis, for all evidence points to so-called inherited or congenital syphilis as being communicated to the child through the mother. But that is another story, too elaborate to go into now.

My point is that when a child is the subject of Friedreich's Ataxia, careful search should be made for any clues pointing to syphilis, and the mother treated *secundum artem* by means of mercury in her next pregnancies. In women, be it remembered, syphilis turns up unexpectedly at times (2). But even apart from any positive indication, this procedure would perhaps be worth trying, in order to prevent, if possible, the development of the Friedreich condition in future offspring once a child had been affected by the ataxia. In the latter case, too, the offspring of future pregnancies might themselves benefit by the early administration of mercury to them. The cases recorded by Bayet do not appear to have had any treatment of the kind, nor does he suggest prophylactic treatment of the pregnant mother.

ON THE CHOICE OF GELATINS FOR BACTERIAL CULTURE MEDIA.

By T. THORNE BAKER, F.C.S.

Much attention has been devoted to the preparation of gelatin and other culture media for bacteriological work, but too little attention has been paid to the choice of the gelatin itself. During the past five years we have had to make a very extensive study of gelatins, and although our primary object was not the preparation of culture media, much information applicable to that work was obtained.

Gelation culture media should be perfectly transparent, and not in the least cloudy, and the jelly should be of such consistency that it does not too easily liquefy. Many gelatin media liquefy so readily that after forty-eight hour's cultivation of a liquefying organism the tubes must be watched almost hourly, as the shape and character of the growths is soon lost owing to the liquefaction.

Gelatins rich in the bony matter known as chondrin precipitate this substance during the boiling after neutralisation, and hence the filtration of the sterile medium through papier Chardin is difficult, as the pores of the paper soon become clogged; moreover, the setting power of a gelatin rich in chondrin seems to deteriorate readily on its losing this constituent.

When selecting a gelatin it is desirable to test it for acidity and for hardness. A one per cent. solution in distilled water may conveniently be used, phenolphthalein solution being added, and the necessary quantity of decinormal caustic potash solution ascertained for its neutralisation. All gelatins contain a large number of bacteria, mainly air organisms, cocci and bacilli of various sizes, but some are due to the water in which the hides are soaked; in the manufacture of gelatin the hides are steeped in water containing lime for several weeks, and a bacterial analysis we made of this water showed it to contain an excessively large number of bacteria, chiefly motile bacilli. The acidity of the gelatin depends largely upon the number of bacteria it contains, and the setting or melting point also, hence it is very desirable to choose a gelatin as free as possible from the presence of micro-organisms.

The melting point is most conveniently determined in the following way: A 10 per cent. solution is prepared by soaking ten grains of the sample in 100 ccm. distilled water for an hour, then dissolving it with the aid of heat, not, however, letting the temperature rise above 100° F. A test-tube is one-half filled with the gelatin solution, and allowed to thoroughly set, during twenty-four hours if possible; it is then laid horizontally on the shelf of a small hot-water oven, the door of which is left open, and the oven gradually heated, the thermometer being carefully watched. At some temperature between 88° F. and 110° F. the jelly will begin to melt, and the surface half-way up the tube will sag more and more until it begins to run; the temperature at which this takes place will be the melting-point of the solution.

If a specially hard medium is required, a very small percentage of chrome alum may be used provided, of course, that it does not cause inhibition or involution of the micro-organisms to be cultivated. The effect of potash and chrome alums on the melting point of a ten per cent. solution of a certain brand of gelatin was as follows:—

	Quantity per cubic centimetre.	Melting Point.
Potash alum ..	.0024 gm.	97·5° F.
,, ..	.0048 ,,	102.0° F.
Chrome alum ..	.0003 ,,	119.5° F.
,, ..	.0006 ,,	133.0° F.
,, ..	.0010 ,,	above 180° F.

It may be assumed that the resisting power to liquefaction by bacteria is directly proportional to the melting point.

Coignet, Drescher, Heinrich, Simeon, Koepff are the principal continental makes of gelatin; Heinrich's brand the hardest as far as our tests have shown; Nelson and Luton are the English makes of first importance, and the latter needs special mention, since it is unusually free from bacteria, and its melting point is high; it is also exceptionally transparent and filters readily. In many instances where we have had to make several sub-cultivations without examination, we have used a medium prepared by adding one grain per cent. each of somatose and peptone, ·5 gm. sodium, sodium chloride and ten grains Luton gelatin, neutralising and boiling for thirty minutes. The medium has been so clear that no filtration has been necessary and it has proved satisfactory for all organisms so far experimented with; the low percentage of chondrin in this gelatin is also in its favour.

At Guy's Hospital Mr. F. Newland-Pedley, F.R.C.S., L.D.S., has been appointed consulting dental surgeon to the hospital; Mr. H. L. Pillin and Mr. M. F. Hopson dental surgeons; and Dr. J. W. H. Eyre bacteriologist.

SOME FURTHER REFLECTIONS
ON
CANCER AND ITS TREATMENT.

By J. A. SHAW-MACKENZIE, M.D.Lond.

The local atrophy and degeneration of a cancerous growth induced by subcutaneous injections of trypsin in the neighbourhood of a tumour or into the substance of the tumour itself cannot be accepted as evidence of the successful treatment of cancer. This statement is based upon the experience of actual facts as proved in cases which have been under my care, or which have come under my observation. Moreover, in a large number of cases the growth itself is inaccessible to local injection. Again, in the instances in which direct injection into the tumour or into its periphery has been practised—a method of treatment I have never personally recommended—the extreme amount of physical suffering has been the invariable result.

Presuming, as I have done, that the causative factor in the cell proliferation of cancer was a deficiency of trypsin, the natural inference seemed to be that the difficulty of reaching inaccessible growths would be met by injections of a solution of trypsin at a distance from the growth, the assumption being that the trypsin would reach the site of disease through the circulation, or supplement the general deficiency underlying its manifestation. But that assumption does not now seem so easy of acceptation, inasmuch as this method of administration does not accord with the view generally admitted that the blood possesses or acquires certain anti-tryptic properties.

(1) According to S. G. Hedin, (*a*) normal serum has a decided anti-tryptic action, and trypsin and its anti-body undoubtedly in more than one respect behave in a way similar to some toxins and their anti-bodies. He shows moreover that the anti-body can be completely saturated by using a sufficient amount of trypsin, though on the other hand it has been found impossible to completely neutralise all trypsin by an excess of anti-body. Attention has recently been drawn by more than one observer to this view, viz., that trypsin acting as a toxin, the production and use of its anti-body cannot be lost sight of in the therapeutic employment of trypsin in the treatment of cancer.

As long ago as November, 1905, Mr. F. W. Gamble drew my attention to this aspect of the problem. He advanced the opinion that the deficiency or absence of trypsin would imply the non-production of its anti-body, a substance which might be regarded as physiologically essential, the absence of which might conduce to cell proliferation. In such cases, trypsin, regarded as a toxin, if injected in too large doses, would damage the cells before they were able to produce its anti-body, whilst small doses would bring about a considerable increase of anti-tryptic power. In accordance with this view, he further observed that the reaction of individuals to trypsin might differ according to their capacity to produce its anti-body, while, even in some this capacity might be absent, necessitating the resort to the administration of anti-bodies, prepared after the well-known methods for obtaining anti-toxic sera.

The question of dosage and the proper control of this toxic agent, therefore, as also from the first, have claimed my most serious attention, and in proof that such caution is necessary, coma, following injections of trypsin, has been reported to me in at least two cases in the actual practice of others. In other cases it has been obvious that reaction, both locally and in the tumour itself, varies in different individuals, the dosage and strength of the solution remaining the same. In truth, my experience has taught me that each case can only be treated, so far as the dosage of trypsin is concerned, in accordance with its special requirements, that is to say, that in some more trypsin is requisite, in others less. Moreover, in a certain proportion of cases my experience has taught me that trypsin is contra-indicated, as proved by the apparent advance of the disease instead of its retrocession, through trypsin having unfortunately and inadvisedly been given to the patient.

I have myself attempted to draw a clinical differentiation between those cases of carcinoma in which glycosuria is present, or a history of diabetes is present in one or other member of the same family and those in which it does not obtain, but rather a long history of constipation or gall stones. In the former, the "liver or pancreas" (*b*) is presumably at fault (glycogenic theory) and trypsin indicated; in the latter, the liver (cholesterinic theory) and the method of treatment introduced by Mr. J. H. Webb by sodium oleate injections and oral administration of purified ox gall, indicated. Furthermore, my impression is that in cases in which there is a "specific" history, trypsin is not indicated. I desire to lay particular stress on these points because it seems to have been assumed by many that the administration of large doses of trypsin is a method which I advise, and that I recommend trypsin alone to the exclusion of other methods of treatment.

For some considerable period a large number of examinations of the opsonic index of the blood to *m. neoformans* has been made for me by Dr. Aylmer May, and by Dr. J. C. Matthews, in patients undergoing the trypsin treatment under my care. From these examinations it has been shown that the index may be raised slightly but for the most part remains normal, in contradistinction to the irregular and characteristic indices in cases of advanced and untreated carcinoma; in other words, auto-inoculation appears to be prevented, coincident with freedom from fœtor and pain. They have seemed to show also that in certain cases the dosage might be increased. How far these results may be due to chian turpentine injections—a method of administration originally introduced by Col. T. Ligertwood, C.B., M.D., and myself (*c*), and which I generally use in addition—I cannot say. At the same time these examinations have not shown the characteristic curves witnessed in cases after inoculations of the *m. neoformans* vaccine. It has seemed obvious from this that the increased leucocytosis, following the use of chian turpentine injections, which I have demonstrated, bears no relation to the opsonic index; that whereas by analogy to other toxins the trypsin injections should be "interspaced," the index to *m. neoformans* is not the "tryptic" index.

In this regard, I may point out that the treatment of inoperable cancer by the method of Sir A. E. Wright (*d*) with vaccines of the *m. neoformans* controlled by its opsonic index, coupled with the probability, as it seemed to me, that this micro-organism belonged to the tryptic group, led me to consider that the same control might be applicable to the trypsin injections. (*a*) The results show, however, that the tryptic index must be sought for in other directions. For example, a direct method of estimating the tryptic or anti-tryptic power of the blood *in vitro* has been introduced by Sir A. E. Wright, and it will therefore be possible to determine not only the normal anti-tryptic value of the blood under different conditions, but also the action of trypsin administered subcutaneously, and its precise dosage. In this connection it may be pointed out that the digestive properties of leucocytes are considered by Sir A. E. Wright to be due to a ferment apparently identical with trypsin.

(2) There is, however, another aspect of this question which cannot be lost sight of - viz., the natural production of trypsin in the body and its aids.

Admitting that a presumed deficiency in the intestinal tract may be supplemented by the therapeutic employment of trypsin orally; recognizing beneficial local and general effects by its local application and introduction into the circulation by one means or another, the problem of treatment, in all probability, resolves itself into the best means of increasing its action or its production in the body or tissues.

It is known that the stimulus of food and acids excites the alkaline saliva. This promotes the gastric acidity, and the acid chyme in turn excites the alkaline secretions of the pancreas, liver and intestinal glands. The supply is regulated by the demand till equilibrium is established. Professor E. H. Starling, in the Croonian Lectures on "The Chemical Correlation of the Functions of the Body" (*The Lancet*, August, 1905) not only drew attention to this mechanism, but showed that the pancreas is stimulated to secretion, chemically, by the substance secretin, while the trypsinogen of the pancreas is converted into trypsin by the ferment of the intestinal glands. Professor B. Moore (*e*) has shown that the presence of free hydrochloric acid in the gastric contents is diminished or absent in cases of malignant disease of organs other than the stomach. Obviously, therefore, inhibition of the pancreatic, liver and intestinal functions follows on the diminution or absence of the gastric acidity. It is known also that ingestion of hydrochloric acid doubles the amount of the pancreatic secretion (*f*), though the secretion itself is devoid of proteolytic qualities till activated by the intestinal juice, the activity being still further increased by the bile.

Such considerations no doubt in part explain the value of hydrochloric acid recommended as treatment in cases of carcinoma no less than the beneficial results obtained by my recommendation of preparations of the intestinal glands and further administration of the bile salts. The power of the intestinal secretion, however, does not end here, for it plays an important *rôle* in carbohydrate metabolism.

A similar adaptation or correlation in all probability takes place in the tissues themselves. As Professor Starling has pointed out, the stationary condition of any given cell is the result of equilibrium between two sets of processes, one causing a building up of the cell, the other a breaking down. Dr. H. M. Vernon (*g*), to whose researches on another and, in all probability, the most important proteolytic ferment of the body, erepsin, universally present in animal tissues, and common to all animal tissues and organs, I have elsewhere drawn attention (*h*), holds that probably the various intra-cellular proteolytic ferments, whether those acting in an acid medium or those acting in an alkaline, form a fairly constant constituent of each individual tissue. In this respect quantitative comparison is made between the lineo-β-protease or proteolytic ferment, which acts in an acid medium (S. G. Hedin), and erepsin or proteolytic ferment, which acts in an alkaline.

The first class of adaptations noted by Professor Starling includes those reactions of the body to chemical poisons produced by bacteria, "and represents one of the most important means by which the body maintains itself in the struggle for existence." Such adaptation, correlation, and reaction is witnessed, as it seems to me, in the increase of ereptic power of the tissues in septicæmia (one case) and in miliary tuberculosis (one case) noted by Dr. Vernon.

The same increase exists in carcinoma. As far as the limited number of cases indicate, noted by Dr. Vernon, in two cases of cancer (stomach, bladder), the ereptic power was markedly increased in the kidney, liver and cardiac muscle; in a third case (secondary, liver) an increase was observed in the liver tissues alone. In this it would seem to me that we have a condition comparable to the adaptation, correlation and reaction of the healthy tissues to bacteria and their toxins and opsonins. Viewing the autolytic acid ferment (or ferments) of cancerous tissues (Petry; Blumenthal; "peptic," (J. Beard) (*i*) as a toxin it would appear as it seems to me to call forth the ereptic ferment irregularly, uncontrolled and unequal to the demand, save in rare instances of spontaneous cure. Presuming initial, local or general deficiency of the ereptic ferment in carcinoma, as well illustrated in a fourth case (rectal) noted by Dr. Vernon, in which presumably also the tissues were not capable of reaction, preparations of the

---

(*a*) Since the above was written I have received an interesting letter from Dr. D. Montgomerie Paton, of Melbourne, in which the question of anti-bodies and anti-trypsin is considered. His view is that by trypsin injections and the use of it and other digestive agents orally, an ACTIVE resistance to the *m. neoformans*, which he regards as a variety of staphylococcus, in some measure may be obtained, whereas by the oral use of anti-diphtheritic serum, which he has long advocated in carcinoma and in some bacterial infections, a similar result is obtained, PASSIVELY. He demonstrates the passive raising of the opsonic index to staphylococci by the action of normal and immune serums, orally administered, and believes that trypsin injections would do the same actively. (Vide "New Serum Therapy," by D Montgomerie Paton. Bailliere, Tindall and Cox, London.)

intestinal glands and liver rich in this ferment were made for me by Mr. F. W. Gamble for therapeutic use in the treatment of cancer, in the same way as originally he prepared trypsin injections (Allen and Hanbury's) and pancreatic preparations. (*j*).

In this connection it is of interest to note that Professor von Leyden, of Berlin, holds that cancerous growth is due to insufficiency of a proteolytic ferment of the liver.

In originally drawing attention to the increased ereptic power of the tissues noted by Dr. Vernon in the above cases, I suggested also that it might be compensatory to an increased autolytic acid ferment. The converse position cannot be lost sight of, viz., that this increased autolytic condition of the tissues may be correlated or adapted to an increased alkalinity. If so, by analogy with the mechanism of peptic secretion a direct stimulus, psychical, or amylolytic, may be presumed. In such respect Dr. Francis Hare notes in his work "The Food Factor in Disease," section 708, "a chemical, bio-chemical, or metabolic hypothesis for the etiology of cancer" in referring to the work of John Rogers, Junr. (New York), that "it has been known for some time that cancerous tissue contains enzymes, but Dr. Buxton, of the Cornell Medical College, has shown that the most abundant and constant enzyme present is the amylolytic. Conformably, glycogen is found in all tumours in a quantity varying directly with the malignancy of the disease." Again, on the other hand, according to M. Hartog (*k*), in addition to a saccharoid substance, a peptonising ferment, active only in presence of dilute acids, is present in the developing blastoderm of the chick, and Dr. Vernon notes that the ereptic power of the tissues of the guinea-pig, rabbit, and cat, is at a minimum in the earliest stages of development; that it increases steadily during intra-uterine life and for the first few days of postnatal existence, after which it remains constant.

It would appear, therefore, that from the earliest stages of development the intra-cellular proteolytic ferments which act in an alkaline medium are adapted or correlated to those which act in an acid medium; that chiefly associated with failure of the alkaline proteolytic ferments, due to various causes, local, congenital, or advancing years, reversion to the peptonising ferment, which is active only in presence of dilute acids, obtains, whilst cell proliferation proceeds in the presence of glycogen and amylolytic ferment, for the latter by itself is unable to break up the proteid-glycogen molecule of the living tissues, or still further in the absence of the intestinal ferments convert maltose into glucose.

Not long after the appearance of Professor Starling's lectures, in which he further concludes that the growth of the mammary glands during pregnancy was due to the assimilatory, building up, or inhibitory effects of a specific hormone or stimulus produced in the fœtus, I received a letter from Mr. J. H. Webb, of Melbourne, to whose original work (*l*) on the treatment of cancer I have so often drawn attention.

He wrote that he had read Professor Starling's lectures in the *Lancet* with the greatest interest; that some eight years previously he had seen a woman suffering from a large intrathoracic, sarcomatous growth involving the shoulder, and pushing the scapula out of place. She did not suffer much acute pain, but she had considerable dyspnœa, and the heart was displaced; it was of course inoperable, and he treated her with freshly prepared animal fœtal extracts. To his astonishment the tumour began to slowly diminish; in about a year's time it had entirely disappeared and eight years later the patient was apparently in perfect health, though the superficial veins remained dilated. He remarked that though one case goes for little, he fancied the remedy for sarcoma must be in the fœtal tissues. In this case it is not improbable that in thus administering an acid extract he may have been administering a fœtal secretion, and that one or other excited the dissimilatory, breaking down, ereptic, or tryptic ferment in his patient. In this connection it is of interest to note that in some rare instances the occurrence of pregnancy has been known to arrest, even to cure, pre-existing carcinoma in the mother. The admitted fact of spontaneous arrest and cure of the disease not connected with pregnancy, inspires the hope that, if so, "it is by no means improbable that the curative process may be forwarded by a recourse to those measures with which art is furnished."

Regarding therefore the alkaline proteolytic ferments as defensive factors, and the cell proliferation of cancer due chiefly to their deficiency or absence, the proper method of administration would seem to be the use of small doses subcutaneously, with larger doses orally; or alternatively, and suggestively the opposite, viz., the use of the acid toxins of the tissues, animal fœtal extracts, or of the growth itself.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

TWO OPERATIONS FOR APPENDICITIS AFTER SUBSIDENCE OF ACUTE SYMPTOMS.—MR. JAMES BERRY operated on a boy, æt. 15, who had been admitted nineteen days previously on the third day of a very acute first attack of appendicitis with peritonitis. On admission his temperature was 100.4, pulse 128, the abdomen tender, rigid and painful; vomiting also was present. He was kept quiet in bed, purgatives and enemata were avoided, care was taken not to give any food by the mouth for the first ten days. All the acute symptoms rapidly subsided and operation was now undertaken, as Mr. Berry pointed out, at a much more favourable period, than on the patient's admission there being at present no acute symptoms of any kind. On opening the abdomen, numerous recent slight adhesions over a large portion of the abdomen afforded abundant evidence of the extensive peritonitis that had existed when the boy was first seen. The appendix was found deeply seated below the cæcum; the tip was firmly adherent, perforated, and surrounded by a small abscess cavity, evidently the remains of the previously widespread inflammation. Removal of the appendix presented no difficulty and the wound was closed without drainage.

The second case operated on was similar, but much less severe. The patient was a woman, æt. 24, who had been admitted on the second day of her fourth attack of acute appendicitis. The present operation was performed eight days after admission, when the temperature and pulse, which on admission had been 101 to and 108, had both fallen to normal, 96 and 70. The intervening treatment had been similar to that employed in the preceding case. At the operation the appendix was found greatly thickened, adherent, perforated, and connected with a small abscess. The mesentery was tied, the whole appendix removed, and the stump buried in the cæcum by means of a purse-string suture. The wound was closed without drainage. Mr. Berry said that this was a method he employed in the vast majority of cases of acute appendicitis in his wards. He thought that operation was very rarely needed in most cases of acute appendicitis during the acute stage, provided they were properly treated from the beginning. Absolute rest in bed, no food by the mouth for the first few days, and abstention from purgatives and enemata were the main points in the treatment. The injudicious and indiscriminate use of purgatives and enemata he considered responsible to a great extent for the modern mortality of the complaint, whilst he was afraid that indiscriminate and hasty operation undertaken in the early and acute stage was also responsible for a good deal of it. Localisation of the inflammation would be found to occur in nearly all cases, provided the parts were kept strictly at rest, and this was not possible if they were frequently irritated or disturbed by purgatives and enemata. He thought that when the inflammation had become localised operation could be undertaken with much less danger to the patient and a far greater prospect of a successful issue. There were, however, a few—a very few—cases of acute appendicitis in which immediate operation was demanded—cases of so-called fulminating appendicitis, cases of sudden rupture of an abscess, cases with acute intestinal obstruction, and some few cases of general peritonitis. In the latter condition, however, the less done at the operation the better, a small incision being all that is usually required.

It is satisfactory to state that a week after operation both patients are doing well in every way.

TRANSACTIONS OF SOCIETIES.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

Meeting held Friday, July 12th, 1907.

The President, Mr. Priestley Smith, F.R.C.S., in the Chair.

Dr. Fukala, of Vienna, read a paper dealing with the

TREATMENT OF A VARIETY OF EYE CONDITIONS.

For marginal blepharitis he advocated an 8 per cent. to 10 per cent. solution of silver nitrate applied to the edges of the lids daily, care being taken that none of the solution enters the eye. For scleritis, both of the superficial and deep types, he recommended the daily application of a 1 in 4,000 solution of perchloride of mercury. The procedure being to first anæsthetize the eye by cocaine, and then with a pledget of cotton wool dipped in the solution to gently rub the sclerotic with a circular movement around, but not touching the cornea. This was thought to influence the ciliary blood vessels. Similar treatment was stated to be effective against chondritis with vitreous opacities, and also occasionally against embolism of the central artery of the retina.

Mr. W. H. Jessop read a paper on three cases of

ACUTE UNI-OCULAR OPTIC NEURITIS

in boys, accompanied by great loss of vision and complete recovery. The cases were three public school boys, æt. 12, 17 and 14. In each there was in one eye marked papillitis, the swelling of the optic disc being about 1 mm., and the vision was reduced to counting fingers. No cause could be found in two of the cases; but in one of them two months after the commencement of the papillitis an abscess discharging a quarter of a pint of pus broke into the rectum. He was operated on afterwards for appendicitis. The probability is that all cases are due to toxæmia. In each case the acuity of vision returned to the normal, in two patients after two months, and in the third after four months. In two cases there was a marked central scotoma, and probably also in the third. So that besides papillitis there was also retrobulbar neuritis. The treatment adopted was mercurial inunctions, iodide of potassium and protection of eyes by peacock green glasses. The great point is the prognosis, as though the vision is much reduced there is complete recovery with normal acuity of vision and normal fields, but the optic nerves remained slightly pale.

In the discussion on this paper, in which Messrs. Marcus Gunn, W. Holmes Spicer, Arnold Lawson, J. Taylor, and others joined, several similar cases were mentioned. The condition was held to be one of retrobulbar neuritis, possibly upon a toxæmic basis, and the prognosis on the whole good, with little or no diminution in visual acuity.

Mr. A. Lawson showed a case of "Thiersch grafting for symblepharon, the result of pemphigus seven years after operation." The left eye has kept well, and although some slight shrinkage has gone on, movements and vision remain good. In the right eye the shrinking process went on somewhat more rapidly, so that two years ago it was necessary to do a further grafting operation, since when the eye has remained well.

Cases were also shown by Messrs. L. V. Cargill ("Solitary Quiescent Tubercle of the Choroid"), S. Stephenson ("Curious Ophthalmoscopic Change"), and A. McNab ("Congenital Opacity of the Cornea in three members of one Family").

ROYAL SOCIETY OF MEDICINE.

The Therapeutical Section on Saturday, July 6th, met at Oxford University. The visit was arranged for the Therapeutical Society before it dissolved, and much regret was felt at the absence of Dr. French, who was hon. secretary of that Society, he was prevented from being present through illness, from which he is happily now recovering.

The members were received at the entrance to Queen's College by Sir Thiselton-Dyer, the first president of the old Society. After a glance at the buildings and some of the other colleges, he conducted the party to the Museum, where Professor Osler was already waiting ready to point out the beauties of the library and show the way to the laboratories.

The first visited was that of Professor Gotch, who explained some of his most recent investigations of the action of the heart. He pointed out that his predecessor, Professor Burdon Sanderson, had conducted his experiments on the empty heart, which revealed that the ventricular contraction began at the base and terminated at the apex. However, Professor Gotch has by delicate electrical experiment on the active heart *in situ*, shown that the contraction commences at the base, travels to the apex and terminates at the aortic base, this was graphically displayed, and many interesting diagrams and photographs were shown.

He next demonstrated a means of at once determining the point of near vision of anyone, the method depending on the different focal lengths of the red and violet rays.

Dr. Ramsden in the same laboratory had arranged a number of beautiful experiments, which he described determining the "Separation of Solids in the Surface-layers, of Solutions and Suspensions."

Proceeding to the Anatomical Rooms, Professor Arthur Thomson showed a thorax with complete transposition of the viscera; and a dissection of a calf's heart displaying to perfection the auriculo-ventricular bundle (Hiss), and demonstrating how important a structure it is; also some enlarged photographs (stereoscopic) of the very early human embryo.

In the Pathological Rooms there was an exhibition of macroscopic and microscopic specimens, and Dr. Gibson gave a demonstration of Jacquet's Polygraph (modified) on a lad.

Lunch followed in Queen's College, and in the afternoon many places of interest including the Botanical Gardens were visited.

Professor Osler gave a garden party at his home, to which all were invited, he had laid out for inspection some of his choicest, rare and interesting folios, which everyone thoroughly enjoyed the privilege of examining.

The Section dined in the evening at Queen's College. Sir James Sawyer proposed the health of the President, Dr. T. E. Burton Brown, C.I.E., he referred to the good work done by the Society of which he was the "Father," remarked on the fitness of seeing him president of the new Section, and hoped for greater things in the future.

Dr. **Burton Brown** replied and thanked the officials of Queen's College for their courtesy in inviting the members to that College, and in placing rooms at the disposal of those who desired to remain until Monday.

Dr. Cecil Wall, through whose good offices the visit was rendered possible, acted as cicerone, and showed every attention and kindness to the party.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, July 14th 1907.

Treatment of Metritis.

For cauterising the cavity of the uterus, liquid caustics are preferable to solid caustics. They should be applied by means of a plug of cotton, wet with a solution of iodine, 6 dr., phenic acid 4 oz., glycerine, 8 oz.; or chloride of zinc, 1—2; nitric acid; pure phenic acid; formol, 1—3.

Curettage, according to Pozzi, is the rational treatment of chronic metritis where the simple treatment (vaginal and intra-uterine injections) fails, and should not be delayed too long for fear of exposing the parenchyma of the uterus to follicular degenerescence, and the possible propagation of the lesions to the tubes.

Certain authors, on the contrary, consider the operation of curettage absolutely counter-indicated. "Curettage," says Marion, "should be prescribed in non-hæmorrhagic acute, or chronic metritis, and in cases where hæmorrhagic metritis is complicated with lesions of the Fallopian tubes."

For Professor Loubeyran, the operation was only indicated in those cases of chronic metritis, where all other treatment had been given a long trial and without success.

Ulcerations of the os should be touched every two days with tincture of iodine, weak nitric acid, or chloride of zinc, 1-10. After cauterising, the vagina should be irrigated and a plug of antiseptic gauze inserted. Where the cervix was much jagged or hypertrophied from follicular degenerescence, the parts should be excised.

Hæmorrhagic metritis is best treated by rest in bed, prolonged vaginal injections with very hot water (122° F.), and the administration of hydrastis canadiensis, viburnum prunifolium, hamamelis virginica, or ergot of rye. If the hæmorrhage does not cease, plugging of the vagina with antiseptic gauze will be necessary.

The operative treatment is reserved for the cases where retention of the placenta is suspected. The os is dilated and the cavity irrigated, after which a digital curettage is made, or, if necessary, a curettage. In case of degenerescence of the mucous membrane, curettage is also necessary. In rebellious cases, hysterectomy should be performed.

For chronic painful metritis, the cervix should be painted, two or three times a week, with the caustics above-mentioned and plugs of glycerine or ichthyol applied. Hot vaginal injections and scarifications of the os are very useful. Where every treatment fails, hysterectomy is the only resource.

The Paralysis of Diphtheria.

According to Professor Comby, the most efficacious treatment of paralysis as a complication of diphtheria is that of injections of the serum of Roux. It always succeeds if employed promptly. Three drachms should be injected each day until improvement takes place.

A Differential Sign of the Origin of Pain.

Pain is either of organic or psychic origin, and frequently the distinction is difficult. M. Lorvi observed that the dilatation of the pupil was in direct relation with painful sensations. In the healthy man, if strong pressure is made on the testicle, this sign is observed, while in an individual suffering from ataxy, where the testicle is insensible, dilatation of the pupil is not observed.

According to the same author, dilatation of the pupil produced by pain allows distinction to be made between pain of organic origin and that of hysteria.

Another author made numerous experiments along these lines and came to the same conclusion. In healthy persons, the painful reflex invariably existed, the dilatation of the pupil was affected more or less rapidly, according to the intensity of the pain itself, and after the cessation of the pain, the pupil returned slowly to its first dimensions.

In pneumonia, pleurisy, articular rheumatism, sciatica polyneuritis, Pott's disease, appendicitis, ulcer of the stomach, pressure exercised on the painful regions provoked dilatation of the pupil.

On the other hand, in ten cases of hysteria, no enlargement of the pupil was observed when pressure was made over the usual points. Similar negative results were observed in two patients suffering from chlorosis, and eight men affected with traumatic neurosis.

The above facts are of great importance, as by them a distinction can be made between the characters of pain.

GERMANY.

Berlin, July 14th, 1907.

At the German Society for Surgery, Hr. Riesinge read a paper on the

Operative Treatment of Dilatation of the Œsophagus.

He showed a patient who for twelve years had suffered from a deeply-situated diverticulum of the œsophagus. The patient, a female, often vomited in the following morning the remnants of the dinner of the day before, whilst the food of the evening before did not come up. Of two sounds introduced, one, usually the thicker, reached the stomach readily; the other generally passed for a distance of 32 cm. below the line of teeth, but no farther. A Röntgenogram when the œsophagus was filled with a bismuth porridge showed a wide shadow reaching from the second dorsal vertebra to the œsophagus, the lower end of which distinctly bulged out to the right. An operation was decided on on account of the patient's starved condition and the great discomfort caused by the diverticulum. After a preliminary gastric fistula had been formed the whole œsophagus was exposed from the posterior mediastinum; resection of a portion was performed 7 cm. in length from the fourth to the seventh rib, the pleura was separated from the lateral surface of the spine, and the œsophagus was isolated almost to the diaphragm; the pleura was not injured. It was intended to diminish the lumen of the œsophagus by forming folds, but the patient's collapse prevented this. The extensive wound was tamponnaded. After several weeks a strip 15 cm. in length and 1-2 in width was excised; the suture was done in two stages. The operation was quite successful; swallowing was undisturbed and the vomiting ceased.

Hr. Schmitt (Munich) reported a case of

Complications after Resection of the Stomach.

The cases were rare. (1) An extensive resection of the pylorus was performed for carcinoma after Billroth's method. Recovery was uninterrupted, and increase of weight took place. A year and a half afterwards the patient got double pneumonia after a very violent long coughing bout. A small red fluctuating spot formed in the cicatrix of the abdominal wound and opened of itself in a few days, whereupon a large quantity of bile escaped. Within a few days a complete fistula formed from the stump of the duodenum with casting off of the ligature placed there a year and a half before. Gastric digestion remained undisturbed. After freshening the edges, turning in and suturing, healing took place. Probably in consequence of the violent coughing a backward movement of the bile had taken place between the sutured end of duodenum and the gastric fistula, whereby infection of the bile possibly took place. He had seen fistulæ occur twice after such resections of the stomach; lately he had therefore preferred Kocher's method where technically possible.

(2) Total necrosis of the omentum invaginated into the colon with secondary fistula. Extensive resection of the stomach after Kocher's method had been performed with good recovery and good action of the bowels. Three weeks after the operation the abdominal wound opened and a large piece of omentum the size of the hand was cast off. For the next week the evacuations were normal; then suddenly great distention took place on the right side of the abdomen. A small shred of necrotic tissue showed at the opening. On slight traction on the piece of tissue a lump the size of an apple was expelled as by an explosion. This was followed by a great quantity of gas and fæces forcibly expelled. The fistula of the transverse colon closed of itself. The omentum first became gangrenous three weeks after the resection of the stomach, and it had worked its way into the transverse colon which, however, performed its function normally until complete occlusion of the bowel took place. It reminded the speaker of the wanderings of foreign bodies in the intestines.

AUSTRIA.

Vienna, July 7th, 1907.

Cardia-Carcinoma of Stomach.

Eiselberg presented a man, æt. 36, who came to the clinic suffering from inability to swallow food. The sound was applied, but would go no further than the upper part of the cardiac end of the stomach, no matter how fine the sound. Notwithstanding this mechanical inability to pass a sound the patient could sometimes pass food into the organ in the usual way. Carcinoma of the œsophagus was at once diagnosed, but when the weight of the patient was considered, and that he had lost only 9 kilos, or 19 lbs., in two years while this had been going on all the time, such a conclusion as carcinoma was doubtful.

Could it be a "Divertical," forming a sac in the wall of the œsophagus? The patient was given a solution of bismuth, and the Röntgen rays applied, when a large sac of enormous distention was discovered immediately above the cardiac end of the stomach in the œsophagus. Considering the loss of flesh and the probable increase in this direction, the longer it was allowed to remain, Witzel's form of gastrostomy was resolved on as the best operation for this case. After the patient had rested in hospital for a time and appeared to recover, the œsophagoscope was again applied to confirm the diagnosis of a diverticulum in the œsophagus, but nothing further could be discovered. The day before the operation, another examination was made with the rays, when a well-defined sac was observed at the cardiac end of the œsophagus in form of a finger pointing towards the stomach. As no opening from the œsophagus could be detected either by the instrument or the rays, it was now doubtful if the diagnosis were correct, as it might be dilatation caused by spasms of the œsophagus. After comparing the first radiograms with the last, the spasm theory was abandoned and the operation performed. After making the fistular gastrostomy, spasm in the lower end of the œsophagus did set in and complicated the results, so that after another three weeks laparotomy of the stomach had to be performed. The hand was then entered and the œsophagus explored. At first a very fine catheter could only be inserted, which was gradually increased until the thumb could be passed, and after it was fairly dilated the organ was closed and healed up favourably. A No. 24 bougie can now be passed easily by the mouth into the stomach and deglutition is normal.

Contractional Phenomenon of the Stomach.

Kaufmann, from his experiments on animals, distinguishes two separate functions of the stomach occurring one in the cardiac and the other in the antral portion of the organ between which a constricting ring actually makes two water-tight compartments. The antral portion is much more active and vigorous than the cardiac. He found that the food taken into the stomach was concentrated and rolled together in the cardiac end and almost covered with a fine mucous coating, while the fluid was quickly transmitted to the antral portion. To obtain this phenomenon he injected physostigmine, which acts and stimulates the smooth fibres of the stomach and alimentary canal. This produces three contractions (*a*) circular motion, (*b*) longitudinal, and (*c*) cardiac and antral.

Kaufmann considers this an important factor in all operations on the stomach and particularly in gastro-enterostomy, where the functional part of the organ should be considered whether in the cardiac or antral portion.

LETTERS TO THE EDITOR.

THE THERAPEUTICS OF HARROGATE WATERS.

To the Editor of The Medical Press and Circular.

Sir,—I have lately noticed persistent statements in several newspapers hinting at the diminution of the effects of Harrogate waters, and *The Illustrated Journal of Health Resorts*, May–June, 1907, in particular, has published some misleading data regarding the constituents of the waters, and comparing them with several other spas, gives an erroneous statement of their strength and composition.

Under these circumstances I have been prompted to go into the matter, and will show that so far from there being any material alteration in the waters they have not changed in any appreciable degree for a great number of years.

Having compared the different analyses given in the journal referred to, I drew the attention of the authorities here responsible for the management and distribution of the waters, and they have given me sufficient statistics to prove my case.

Allow me to place alongside each other the statement made by the Journal, and an analysis made by the eminent chemist, Professor J. E. Thorpe, C.B. :—

PROFESSOR THORPE.

Saline Constituents Grains per Gallon.	Old Sulphur Well Pump Room	*Health Resort* STATEMENT.
Sodium Sulphydrate ..	5.215	6.50
Barium Chloride	6.566	
Strontium Chloride ..	trace	
Calcium Chloride	43.635	16.75
Magnesium Chloride ..	48.281	17.75
Potassium Chloride ..	9.592	
Lithium Chloride	.753	
Ammonium Chloride ..	1.031	
Sodium Chloride	893.670	.236
Magnesium Bromide ..	2.283	
Magnesium Iodide ..	.113	
Calcium Carbonate	29.768	
Magnesium Carbonate ..	5.953	
Sodium Carbonate ..	..	11.
	1047.561	288.
Sulphuretted Hydrogen	10.16	
Carbon Dioxide........	40.10	
	50.26	

In the first place it will be noticed that the sum total of grains per gallon does not agree with the sum of the different constituents, and as the Journal apparently quotes an analysis by Mr. West, I find the total amount given by him in the official record is 1047.01, and not 288.0–.

The amount given by Professor Thorpe (at a later date than Mr. West's analysis) is 1047.01, so that it can be seen at once that the statement contained in the Journal is entirely wrong, both in total and individual constituents, thus seriously misrepresenting the strength of the Harrogate waters.

Might I be allowed to give a list of the analyses given by leading men since 1794, which shows that the strength of the waters has been consistently maintained, and also that the salts in grains per gallon have scarcely varied during the last seventy years, and they now appear to be as reliable and efficient as ever.

OLD SULPHUR WELL ANALYSES :—

		Total Salts in Grains per gallon.
1794	Dr. Garnett	754.0
1819	Sir C. Seudmore	848.10
1830	Dr. Hunter	1010.5
1844	Mr. West	1047.0
1854	Professor Hoffman	1096.0
1867	„ Muspratt ..	1108.78
1875	„ Thorpe... ..	1047.01
1881	Mr. Davis, F.C.S.	1048.25
1899	„ Townsend, F.C.S. ..	1025.4

In fact without wishing to appear presumptuous it may be fairly said that taken as a whole the treatment here now (waters and baths included) will favourably compare with any other spa, either British or foreign.

I am, Sir, yours truly,
D. D. BROWN, M.R.C.S., L.R.C.P.Lond.
Harrogate.

DENTAL AND COSMETIC QUACKS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am glad that in the fight against quackery—the attempt to expose the whole system before a Royal Commission—dental and cosmetic impostors are not to be overlooked. If the operations of these rogues did not, as they certainly do, inflict injury upon health, it would be still the duty of the State to guard simple and foolish women, the majority of victims, against the robbery, the system of thinly veiled blackmail, which it often really constitutes, and to which they are now helplessly exposed. The safety of this species of quack lies in the fact that there is hardly any maltreatment a nervous woman would not condone rather than expose her folly publicly in a Law Court, as plaintiff in an action for damages. The quack, moreover, in the few cases when pressed, always refunds his plunder and pays damages rather than go into court ; hence exposure of this nefarious traffic is now never effectually made. It cannot be made without the help of a Royal Commission. Within the past few weeks there has been published in a medical paper analyses of fat cures, under cloak of selling which many quacks are making fortunes. These cures, when not made up of slightly perfumed fat, were composed of water strongly acidulate with the cheapest of chemicals. Retailed at about 2s. 6d. an ounce, the intrinsic value of this mixture of which the uselessness for its purpose could be easily demonstrated, was a small fraction of a farthing. The cheap artificial tooth fraud could be as easily exposed. If the Food and Drugs Acts and the Merchandise Marks Acts have been devised for prevention of much less dishonest practices in trade, is it too much to ask the Legislature to protect the public against the far more hurtful forms of medical fraud which you, Sir, are exposing ? It is to be hoped that Mr. Sewill's suggestion of a Royal Commission will speedily be taken up by professional organisations.

I am, Sir, yours truly,
A HOSPITAL DENTIST.
July 13th, 1907.

OBITUARY.

SIR W. H. BROADBENT, PHYSICIAN-IN-ORDINARY TO THE KING.

WE regret to record the death, on the 10th instant, of Sir William Henry Broadbent, K.C.V.O., M.D., F.R.S., Physician in Ordinary to the King, at his house in Brook Street, London. Sir William Broadbent, some nine months ago had a severe attack of influenza, which was followed by an attack of pneumonia and empyema, necessitating an operation. From this illness his recovery was slow, and he never resumed his active occupation.

Sir William was a son of the late Mr. John Broadbent, of Longwood Edge, was born in January, 1835, and received his general education at Huddersfield and at Owens College, Manchester. His professional studies were carried on in Manchester and partly in Paris, and later at St. Mary's Hospital, London. He became M.B. of the University of London in 1858, and M.D. of the same University in 1860, and a member of the College of Physicians in the year following. At a later date the latter body elected him a Fellow, and on two occasions appointed him to the important office of Censor. One of his first appointments in London was in connection with the Western General Dispensary, but it was not long before he was appointed to the staff of his own hospital, St. Mary's, working in its medical school for many years as lecturer on clinical medicine.

He completed two terms of office as honorary physician and later as consulting physician. Sir William became connected with the Court at a comparatively early date. He was summoned to attend the Prince of Wales, then Prince George of Wales, when brought to Marlborough House from Sandringham, suffering from typhoid fever in 1891. He was also one of the physicians in attendance on the late Duke of Clarence in the following year. Similarly he was frequently at the bedside of Queen Victoria during her last days in 1901, and more recently took part in the treatment of King Edward during the illness which led to the postponement of his Coronation in 1902. Some three years before her death the late Queen appointed him to the position of Physician Extra-ordinary, and the King on his accession confirmed him in the office of Physician in Ordinary, which he held when the King was Prince of Wales.

Sir William Broadbent was closely connected with the professional life of London. He filled the office of President of the Harveian Society, the Clinical, the Neurological Societies, and the Medical Society of London. He was also a vice-president of the Cancer

Research Fund, and President of the British Medical Benevolent Fund, besides playing an important part in the organisation and conduct of the National Association for the Prevention of Tuberculosis. He received honorary degrees from Edinburgh, Leeds, St. Andrews, Canada and the United States, and was a Fellow of the Royal Society of England. He was also honorary member of a great number of learned societies of Berlin, Vienna, and other continental cities.

Sir William's contributions to literature were numerous and he wrote several books, some of which have gone through many editions. The best known and most popular was that upon "Heart Disease," while among others may be specially mentioned "The Pulse," and "The Mechanism of Speech and thought."

Sir William was created a baronet in 1893, and in the year of the Coronation he was created K.C.V.O. He was also made Commander of the Legion of Honour, on the occasion of the visit of a number of distinguished English medical men to Paris, some years since.

In 1863 Sir William married a daughter of Mr. John Harpin, who survives him with a family of five children. He is succeeded in the title by his eldest son, John Francis Harpin, who was born in 1865, and is in practice as a physician.

Before his death Sir William Broadbent had been away in the country for five months, having had to abandon practice during that period. In his last illness he was attended by Sir Thomas Barlow, Prof. Osler, and Mr. Edmund Owen. It was only in January last that he celebrated his seventy-second birthday.

By his death one of the foremost figures in the profession has been lost to us. His intellect was essentially that of the sane and wholesome type that confers upon the medical life of our nation its peculiar excellence. A forcible testimony to the personal worth of this great physician is afforded by the warm personal interest and friendship which the Royal Family have always shown in his career.

At the memorial service, held on Saturday last at the Church of St. Peter, the King and Queen were represented by the Hon. Sidney Greville, and the Prince and Princess of Wales by Sir James Reid. Practically all the medical institutions and societies in London were represented, the coffin was covered with wreaths, one being from the Queen, inscribed, "In grateful remembrance, from Alexandra." The funeral afterwards took place at Wendover Churchyard, Buckinghamshire.

SPECIAL REPORTS.

ROYAL COLLEGE OF SURGEONS— ELECTION OF PRESIDENT.

A quarterly meeting of the council of the College took place last Thursday, Mr. Mansell Moullin, Mr Frederick Eve, Mr. Bruce Clarke, and Mr. C. J. Symonds the successful candidates at the recent election of Fellows to the Council, were introduced and took their seats as members of the Council.

Mr. Henry Morris was re-elected president, and Mr. Rickman J. Godlee and Mr. Watson Cheyne, C.B., F.R.S., were elected vice-presidents of the college for the ensuing collegiate year. The following professors and lecturers were appointed :—Dr. Wm. S. Handley, one lecture on therapeutic criteria in cancer; Dr. Victor Bonney, three lectures on the connective tissues in carcinoma; Mr. Donald Armour, three lectures on the surgery of the spinal cord and its membranes; Mr. A. R. Thompson two lectures on the anatomy of the long bones relative to certain fractures, and Dr. F. C. Shrubsall, three lectures on the physical anthropology of the pigmy and negro races of Africa. Arris and Gale lecturers: Dr. F. A. Bainbridge, one lecture on the pathology of acid intoxication; and Mr. Major Greenwood, junr., two lectures on the physiological and pathological effects which follows exposure to compressed air. Erasmus Wilson lecturers: Mr. S. G. Shattock, one lecture on ovarian teratoma; Dr. W. H. Eyre, one lecture on the surgical importance of the pyogenetic activities of diplococcus pneumonia; and Mr. L. S. Dudgeon, one lecture on infection of the urinary tract due to bacillus coli.

The president reported that by the death of Miss Moncrieff Arnott the legacy of £1,000 bequeathed to the college by Mr. James Moncrieff Arnott, a former president of the college, became payable to the college, and that by her will Miss Arnott had left to the college an oil painting of her father. The Museum Committee submitted the revised edition of the catalogue of the physiological series of comparative anatomy in the museum, and also submitted a revised edition of the catalogue of the osteological specimens (man).

The President reported that the vacancy on the Court of Examiners caused by the retirement of Mr. Golding-Bird, would be filled up at the next meeting of the Council on the 25th instant. Mr. Golding-Bird does not intend to seek re-appointment to the office.

A vote of thanks was presented to Sir John Tweedy for presenting Rymer's Fœdera, twenty volumes folio, published in the year 1711, to the library. The council accepted the resignation of Mr. C. R. Hewitt, assistant in the library, and expressed their thanks to him for his services to the college during the past twenty-two years. Mr Hewitt has accepted a librarianship in the Royal Society of Medicine.

In accordance with the recommendation of the committee of management of the two Royal Colleges, it was decided to add the following schools to the list of institutions recognised by the examining board in England for instruction in chemistry and physics: Aldenham School, Elstree, and the Municipal Technical School, Birmingham.

ROYAL COLLEGE OF SURGEONS, IRELAND.— ROYAL VISIT.

On the occasion of the recent Royal visit, the following Address was presented by the College:—

"To His Most Gracious Majesty, Edward VII., King of Great Britain and Ireland and all the Dominions beyond the Seas, Emperor of India; and to Her Most Gracious Majesty, Queen Alexandra. May it please your Majesties,—We, the President, Vice-President, and Council of the Royal College of Surgeons in Ireland, desire to avail ourselves of the presence of your Majesties in Dublin to offer the assurance of our allegiance to your Majesties and our respectful and loyal welcome on the occasion of your gracious visit to Ireland. It is the object of our Royal College to provide highly qualified surgeons who may serve their country in the naval or military services, as well as those others who will devote their lives to the care of the sick in the civil community. Knowing the deep interest your Majesties take in all that concerns the welfare of your subjects and the progress of surgical science, we feel confident that our Royal College may rely on your Majesties' favour in our continued efforts to secure the efficiency of those who seek diplomas.—Signed, on behalf of the Council, Henry R. Swanzy, (President), John Lentaigne (Vice-President), Charles A. Cameron (Secretary). July 11th, 1907."

His Majesty's General Reply.

A copy of his Majesty's general reply was handed to each deputation, and at the conclusion of the presentation of addresses, the King said:—

"Gentlemen,—I thank you for the hearty greetings and cordial welcome which you have tendered to the Queen and to myself, and I accept with sincere gratification your loyal assurances of devotion to my Throne and person. I am pleased to hear of your success in your various spheres of public duty, and I trust that a blessing may continually follow your labours for the prosperity of the country and the welfare of the people. I regret that time does not admit of an individual acknowledgment of your addresses, but I ask you to accept from the Queen and from myself an assurance of our gratification at your kindly reception of us and of our hearty sympathy with you in your efforts for the good of the various communities which you represent."

LABORATORY REPORTS.

PLASMON BISCUITS.

Many articles of food can now be obtained in which the amount of protein has been increased by the incorporation of that valuable proteid, Plasmon. These preparations can be confidently relied on where it is desired to administer protein matter in an easily assimilable form. There are now nine varieties of Plasmon biscuits—plain, sweet, wholemeal, rusks, ginger nuts, fancy, oat, wafer, and cracker, and in these biscuits there is considerably more protein matter than in ordinary kinds. Long experience of Plasmon preparations has caused us to expect a very high standard of excellence from foods bearing this name, and our expectations are not disappointed. So far as these biscuits are concerned, it is evident that careful attention has been paid to the details of their composition and manufacture, with the result that not only are their nutritive values high, but their appearance and flavour will commend themselves to patients.

We have submitted the plain biscuit and the rusk to a chemical examination, and we find the former to contain 20·83 per cent. of proteins, 2·94 per cent. of ash, and 6·38 per cent. of moisture. Plasmon rusks contain 16·27 per cent. of proteins, 6·18 per cent. of moisture, and 1·56 per cent. of mineral matter. The flavouring of this biscuit is excellent. The ratio of albuminoids to carbon-hydrates is, therefore, satisfactorily high. The sole manufacturing rights for Plasmon biscuits have been secured by Messrs. Mackenzie and Mackenzie, of Edinburgh, who have made special arrangements to conserve the full qualities of the Plasmon proportion. Our analyses show that Messrs. Mackenzie and Mackenzie are keeping these preparations up to a high level.

ARMOUR'S EXTRACT OF RED MARROW.

The value of red marrow in certain forms of anæmia has become one of the established facts of modern therapeutics. It is therefore of advantage to medical practitioners to have a trustworthy preparation on the market. An excellent product of the kind is the glycerine extract of red marrow, a bottle of which has just reached us from the well-known laboratories of Armour and Co., Ltd., of London. It is guaranteed to be made from carefully selected fresh material, and to contain all the essential ingredients of red marrow. We have pleasure in drawing the attention of our readers to this elegant and valuable preparation as a remedy in chlorosis and various forms of anæmia and perverted nutrition.

REVIEWS OF BOOKS.

DISEASES OF THE NOSE AND PHARYNX. (a)

This excellent handbook has now reached its fifth edition, a fact which speaks for itself. The plan of the book is very good. It is divided into four parts. The first treats of general considerations, including anatomy, physiology, general diagnosis, and methods of treatment; the second, diseases of the nose and naso-pharynx; the third, diseases of the accessory sinuses; the fourth, diseases of the pharynx.

Written chiefly for the use of students and practitioners, it gives a clear and more or less dogmatic account of the diseases of which it treats. Though aiming at conciseness, the descriptions of the various conditions are very thorough and up-to-date. Indeed, far more so than in some much more pretentious works lately published—for instance, a very good account of the operation for submucous resection of the septum is given in Chapter XVIII., and the latest treatment of that distressing and intractable malady—hay-fever—in Chapter XIII. Some useful formulæ and a good index are added. The binding, printing, and general get-up of the book are excellent.

ANÆSTHETICS (a).

We extend a cordial welcome to the new edition of Dr. Buxton's book, not only as a sign of the increasing interest taken in the subject, but also as it has enabled the author to give us his experience and judgment of the recent advances which have taken place in the practice of anæsthetists. The use of ethyl chloride as a general anæsthetic was in its infancy when the last edition was published, and consequently the book contained a very meagre account of its uses and administration. One can hardly say that the place which this anæsthetic is permanently to assume has been settled yet, but its advantages and limitations are becoming every day more definite. We agree with our author that its field of usefulness is much more circumscribed than it was believed to be by many five years ago, but we cannot agree with him altogether in the comparison which he institutes between it and other anæsthetics. To compare ethyl chloride with ether or chloroform as to safety is, in our opinion, to endeavour to compare things which are not comparable. The conditions under which the administration takes place make all the difference. Under suitable conditions we believe ethyl chloride to be a safe and very useful drug, but one must always bear in mind that it is a most powerful and rapidly acting drug, much more so probably than either ether or chloroform, and consequently its safety will depend to a large extent on a knowledge of its limitations.

Another subject the treatment of which is quite new in this edition of the book, is the dosimetric administration of chloroform, and here Dr. Buxton speaks with the authority of an experience which is probably unrivalled among anæsthetists. Since the introduction of the Vernon-Harcourt and other regulating inhalers the chloroform controversy has assumed a new phase; the dispute is no longer between the merits of ether and chloroform, but between the methods of administration of the latter. Dr. Buxton has demonstrated that, in his hands, at all events, the new method can give excellent results. He says, "From an experience of three years and some thousands of cases, many of the gravest character, I may say, I have found the inhaler fulfils all the purposes for which it was constructed. . . . It is easy to manage, and when once learned will prove reliable and satisfactory. There have been no dangerous symptoms due to the anæsthetic in the cases in which I have used the inhaler, and no failures." This is strong testimony in support of the method, but it is an individual and not a general experience, and other workers have not been so fortunate. In our opinion this phase of the controversy will end as did the former, for it is neither the method nor the drug which constitute the safety, but the knowledge and attention of the administrator. Undoubtedly a careless administrator may be less dangerous with a regulating inhaler than with a Skinner's mask and drop bottle, but the condition is one of less danger and not safety. We believe, as is pointed out in Gill's work on the CHC_{13}-Problem, reviewed in these columns a few weeks since, and as maintained by the Hyderabad Commission, that safety in chloroform administration depends on the maintainence of the integrity of the respiration. With the regulating inhalers, unless this is maintained free, either no anæsthesia or dangerous symptoms will follow, the former most probably, hence the safety. With the drop method of administration if the respiration is kept quite free, an overdose can scarcely be given; but with any obstruction to the breathing danger is more likely to follow if this obstruction is not recognised, and at once corrected, than with the regulating apparatus. It is in the recognition of the various forms of this obstructed breathing that the skill and attention of the administrator are shown, and it is this that confers the element of safety to the administration in his hands. We should like to see more space devoted in works on anæsthetics to this subject, and believe it would be very much more useful to the beginner than elaborate dissertations on different methods. Dr. Buxton has added to this edition of his work a chapter on local anæsthetics which will make the book much more valuable and complete from the point of view of the general practitioner.

(b) "Anæsthetics: Their Uses and Administration." By Dudley W. Buxton, M.D., Administrator of Anæsthetics and Lecturer in University College Hospital. Fourth Edition. London: H. K. Lewis. 1907. 8vo, pp. viii. and 415.

SKIN DISEASES. (*a*)

Of the many dermatological text-books extant few meet the needs of the busy practitioner in dealing adequately with treatment, and being at the same time concise. Dr. Whitfield's handbook should speedily become popular in this respect, for it contains much of practical interest from the therapeutic standpoint without being too bulky. The various diseases of the skin are dealt with in twenty chapters, considerable space being devoted to eczema and its allies. The author has struck the right note here when he says, with regard to treatment, that "the first thing to do is to discover how much is due to external and how much to internal influence." He does not mention, however, the necessity for caution in the application of strong remedies for the eczema of infants, owing to the danger of absorption of such medicaments as carbolic acid, strong mercurials, &c., though the risk of inducing pneumonia from applying evaporating lotions over large surfaces is stated. The alleged danger resulting from the too rapid cure of an infantile eczema is touched upon, and infection by pyogenic organisms, among other factors, is warned against. Most will agree in the reservation of arsenic for eczema of the nails only.

In the matter of classification of skin diseases there are differences of course of opinion but we confess that we do not view with favour the inclusion of seborrhœa capitis under the heading of *pityriasis alba* among the "Diseases due to Vegetable Parasites other than Bacteria," still less do we agree with the description of true seborrhœic dermatitis as one variety of chronic eczema. In this connection may be noticed a good account of the special form of dermatitis known as *discoid eczema*, which has been made a special study of by Dr. Whitfield. The various parasitic affections receive considerable attention. We note that the author states that "there is no justification" for the use of formalin in the treatment of ringworm of the scalp, an assertion with which we are in the fullest accord. A good description is given of the X-Ray technique to be carried out in this class of case. The author is, perhaps, a little inclined to be pessimistic in treatment, in such affections as pityriasis rubra and feigned eruptions, but this is better than being too sanguine. There is a full account of the injuries which may be wrought upon the skin by the use or mis-use of the X-Rays, but we do not find any mention of radium as a therapeutic agent nor of the employment of cataphoretic medication for such conditions as rodent ulcer. Nevertheless, the book is full of good points, well got up, and illustrated by some really telling photographs taken by the author.

SANITARY ENGINEERING AND WATER SUPPLY (*b*).

This volume is the latest addition to Messrs. Longmans' famous Civil Engineering Series, and it forms a worthy addition to this collection. The preparation of the work has occupied the spare time of the author for the last five years. That these periods of leisure have been well spent is obvious, and although there is not very much that is novel or new in the book, Mr. Vernon-Harcourt has served his generation well in writing on a subject so important to the public health. As little as possible technical language has been employed, with the result that those who have hitherto been deterred from a serious study of the subject because of the technicalities, have now at their disposal a trustworthy guide to engineering as applied to water and sewage matters. In the part relating to Water Supply, the sources of supply, its purification, and distribution, are fully discussed, as also is the construction of wells, reservoirs and dams.

The second part dealing with sewage disposal contains a mass of judiciously selected information as to house drainage, the construction of sewage works, the various ways of disposing of the crude or purified sewage and other matter relating to the subject.

The illustrations are clear and well show the points they are intended to illustrate. It is a book that will be of immense service to medical officers and sanitary authorities, as well as to water and sewage engineers, and we can heartily commend it to such. The author is an eminent authority on his subject, and he fully realises the points and details on which it is necessary to lay emphasis. His wide knowledge of the subject enables him to give examples that not only form interesting reading, but are of great service in helping the reader to appreciate the point at issue, and to differentiate between the different methods. We should not be far wrong in characterising the volume as a collation of examples, judiciously interspersed with theory.

BRAIN SURGERY. (*a*)

This volume is an expansion of the author's Lettsonian Lectures for 1906. He seems to have aimed at making it a book of that valuable type that, without giving a complete text-book account of a subject, presents certain aspects from a personal standpoint, and illustrates these aspects from a special experience. It is encouraging to find that this important class of books is increasing, and tend to replace to some extent the stereotyped manuals.

Chapter I. deals from the surgical standpoint with various affections of the meninges. Our increasing knowledge of these affections is illustrated by a description of well-chosen cases, most of which had occurred in the author's own experience. Original contributions to this knowledge are inconspicuous, but the amount given forms a readable summary. We note that the author uncompromisingly advocates progressive methods, in the form of readier recourse to operative measures, in the case of the suppurative meningites. He is hopeful about the future advances that will certainly be made in this direction, and even sees ground for the belief that tuberculous meningitis may yield to similar treatment. Perhaps the most interesting part of this section is the account given of the treatment of hydrocephalus, where the author's personal experience is particularly valuable. On the matter of diagnosis he is less happy, and many of his statements are very open to question. To say, for instance (p. 61) that optic neuritis is, as a rule, a late sign in tuberculous meningitis and an early one in suppurative meningitis, is to render oneself open to misinterpretation. It is only true in so far as tuberculous meningitis is of longer duration than the other, but there is no evidence that relatively optic neuritis is an early sign in the latter, and a late one in the former. Far more important is the fact that optic neuritis is greatly (more than twenty times) more frequent in the former case than in the latter, and this is not even mentioned by the author. On page 57 is the astonishing statement that in a suspected case of typhoid fever an absent knee-jerk or early disc

---

(*b*) "Sanitary Engineering with Respect to Water Supply and Sewage Disposal." By Leveson Francis Vernon-Harcourt, M.A., M.Inst.C.E. Emeritus Professor of Civil Engineering and Surveying, University College, London. Price 14s. net. Pp. 419 and xxi., with 287 illustrations. Medium 8vo, London: Longmans, Green and Company. 1907.

(*a*) "Some Points in the Surgery of the Brain." By Charles A. Ballance, M.S., F.R.C.S. 1907. Pp. 405. London: Macmillan and Company. 15s. net.

changes would be pathognomonic of intra-cranial inflammation. Rolleston has shown that the knee-jerk is absent in 10 per cent. of ordinary cases of typhoid fever; the presence of optic neuritis is, of course, by no means rare in typhoid fever, and is far commoner in cases free from intracranial complications, such as typhoid meningitis, than in those with such complications.

Chapter II. deals with abscess of the brain, and is, perhaps, the most valuable section in the book. A good account of the course of symptoms is given, the classic description by Brissand and Souques being closely followed. The frequency of tuberculous ear disease followed by tuberculous meningitis is insisted on, and the importance of it in diagnosis pointed out. Naturally the author is a strong advocate of the treatment of cerebral abscess according to the principles of surgery now established.

Chapter IV. deals with tumor cerebri, and comprises nearly two-thirds of the volume. A large number of cases are described in detail, many being taken from published records.

It is unfortunate that the author suffers, like many other medical writers, from a lack of interest in English composition, for the smoothness of reading is greatly marred by the results of this. The opening sentence contains a split infinitive, and the impression there created is not effaced by such sentences as that on page 20, in which the following ambiguous or libellous passage occurs: "I successfully removed such a cyst . . . from a patient of Dr. James Taylor, who had narrowly escaped being consigned to a lunatic asylum, where he might possibly have been labelled 'general paralysis,' and died without relief." There are also many verbal inaccuracies, a few of which may be cited. On page 173, "insolvable" occurs in place of "insoluble." M. Lejonne is called Lejeune on pages 319 and 375. In a reference on page 375 to the "Revue de Neurologie," it is not stated whether the *Revue Neurologique* or the *Journal de Neurologie* is meant; as a matter of fact, the reference indicated is in the former of these, but on page 846, not page 840, as stated by the author. *Archiv fur Psychiatrie und Neurologie*, on page 376, should be *Archiv fur Psychiatrie und Newenkaukheiten*. *Deutsche Zeitschrift fur Neurologie* (page 377) should be *Deutsche Zeitschrift fur Newenheilkunde*. The references given are, however, interesting historically. On page 236, the author makes the same mistake that Holmes and Stewart made in their important article on cerebellar tumours of speaking of diadocokinesis as a physical sign of disease. Diadocokinesis is a term invented by Babinski to indicate the capacity rapidly to perform successive movements; impairment of this capacity is a physical sign of disease.

The volume is profusely illustrated with excellent photographs and drawings, many of which, such as those on pages 44, 45, 288, 289, &c., are, however, totally superfluous. It does not pretend to be a systematic treatise on the subjects dealt with, and, naturally, will not be read for this purpose. Its value for any other purpose is greatly lessened by the disorderly arrangement adopted. The book would have been better had the author dealt concisely and fully with the matters on which he is specially qualified to speak, and had he checked his tendencies to range diffusely over a multitude of subjects, from Aphasia to the Evolution of Right-handedness, many of which could be dealt with only superficially and have only an indirect bearing on the questions at issue.

HUMAN PHYSIOLOGY. (a)

Professor Tigerstedt's "Lehrbuch der Physiologie des Menschens," since its first publication in 1897, has found much favour with teachers of physiology. It is but fitting that the field of its influence should be widened by an adequate presentation in English form. This has been ably provided by Dr. Murlin. It is a pleasure to be able to acknowledge the debt of gratitude due to the energy and enterprise of American translators and publishers by English-speaking students for such works as this which we are becoming accustomed to welcome almost as a matter of course from trans-Atlantic sources.

Tigerstedt's work, as Professor Lusk points out in his introduction, is a reliable picture of the scientific structure upon which modern medical practice is based. It is certainly true that good physiology is the only preventive of bad medicine. A work such as this affords that intellectual training which best fits the students to understand and rightly interpret the phenomena of both health and disease. Special attention is devoted, as might be expected, to the mechanism of circulative and nutritional processes, but there is a lack of due proportion in presentation which is disadvantageous to the student. Dr. Murlin states that his purpose has been to bring the work within the reach of the second-year medical student. Whether this object will be attained in America we cannot say, but with the numerous modern well-balanced manuals by recognised teachers now available in this country we fear Professor Tigerstedt's bulky work will have difficulty in securing anything like a position of popularity among the examiner-fearing students of British universities and colleges.

The work, however, is one which should be welcomed by all physiologists and both teachers and students should regard it as a reliable, attractive and judiciously illustrated work for general reading and reference.

(a) "A Text-book of Human Physiology." By Dr. Robert Tigerstedt, Professor of Physiology in the University of Helsingfors, Finland. Translated from the German and Edited by John R. Murlin, A.M., Ph.D., Assistant Professor Physiology in the University and Bellevue Hospital Medical College, New York. London: Sidney Appleton. 1906.

THE PHILOSOPHY AND PATHOLOGY OF WORRY. (a)

"Worry is, in general, a wholly futile and evil thing." This is the dictum of Dr. Saleeby, who writes as a philosophic medical observer, well trained in the methods of the scientist and yet with keen intuitive perception of life's perplexities and problems, as they appear to the ordinary layman. It is a misfortune that it is given to but few writers on matters medical to have the happy gift of presenting scientific truths in form and language suited to the understanding of "the man in the street." Dr. Saleeby is one of the few who possess the gift of imparting sound knowledge in a popular and acceptable manner without the sacrifice of scientific precision. He writes with a wealth of diction and grace of style which mark his works with distinction. In this, his latest volume, he deals with a malady which sooner or later overtakes us nearly all. The study is timely and in this day of stress and strain demands serious attention. It is a work which should be read by every physician and may well be considered by each burden-bearer in life's busy workshop. The nature, significance, and consequences of worry and its associations with bodily and mental disease are thoughtfully dealt with. The evil effects of dulling care by drugs and drinks is graphically portrayed. The worries of childhood and old age, the connections of worry with sex, and psychological states are dealt with in a manner helpful and suggestive. Dr. Saleeby is a bold writer and does not hesitate to express his views dogmatically. An older essayist would doubtless have qualified many of the statements relating to religious worry, and worry as a maker of religions, in regard to which Dr. Saleeby has allowed himself much freedom of thought and liberty in expression. The work throughout is planned on broad and comprehensive lines, and is imbued with a sense of responsibility, a spirit of reverence for man and his noblest manifestations and highest aspirations, and a scientifically-directed altruism which projects itself into the future. We commend the book to all worriers and worried.

(a) "Worry: The Disease of the Age." By C. W. Saleeby, M.D., F.R.S.Edin. Pp. 312. London, Paris, New York, and Melbourne: Cassell and Company, Limited. 1907. Price 6s.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT MEDICAL LITERATURE.

Albuminuria of Adolescence. — Heywood (*The Manchester Medical Chronicle*, June, 1907) discusses the conditions under which serum albumin appears in the urine in otherwise healthy young people. With a view to discovering the frequency and character of residual albuminuria following scarlet fever, the urines of 39 children, all of whom had suffered from scarlet fever, were examined. All the children were apparently perfectly healthy, and in at least 36 of them there never had been any anasarca or symptoms of uræmia. In 21 cases, the urine was examined at some period during the first year following the freedom from isolation; in 15 cases the interval was from one to three years, and in three cases was over three years. The patients' ages varied from 3 to 18 years. In 19 of these patients, the urine was found to contain albumin which was easily demonstrable by ordinary clinical tests. It was further found that the percentage of albuminous cases was about the same for those tested during the first year and for those tested during the second and third years. Further, it was found that the early and late residual albuminuria did not differ much in type. Sex did not appear to have any influence, but the younger the child was when attacked by scarlet fever the less liable did he appear to be to suffer from residual albuminuria. In only one case was the albumin constantly present, and in that case it was subject to cylic variations. Various writers differ considerably as to the number of scarlet fever patients who suffer from albuminuria. The returns from the Metropolitan Asylums Board, dealing with 66,871 cases, put the percentage at 13.67, while Grainger Stewart and Thomson put it at 60 per cent. Heywood concludes that about 50 per cent. of patients attacked by scarlet fever suffer from albuminuria during the course of the disease. As regards prognosis, he believes that the vast majority of cases of albuminuria in the young recover; the minority, which include those cases in which granular and epithelial casts are found, remain unaltered or pass on to chronic granular nephritis. K.

The Prognosis in Transient Glycosuria.—Barringer and Roper (*Amer. Journ. of the Med. Sciences*, June, 1907) discuss this very important question and the relation of this condition to alimentary glycosuria. The writers define transient spontaneous glycosuria as that which occurs occasionally in patients on ordinary diet, and for which none of the various causes of glycosuria can be discovered. Von Noorden has expressed the opinion that such glycosuria is in most cases the warning signal of latent diabetic disease. In order to estimate the value of this opinion, the writers have examined 20 such patients, and find that four of them in from five to eight years have developed mild diabetes, while a considerable number of the remainder showed sugar in the urine on the ingestion of 100 grams of glucose. Of these later cases, the majority eventually became diabetic. The writers consider that "these various facts may be explained by an assumption, which readily suggests itself, that is, the division, broadly, of spontaneous glycosuria into two types: (1) A class essentially diabetic from the onset, in which sugar recurs, which shows constantly glycosuria, and which, at the end of five or more years has become diabetic or probably diabetic. (2) A class quite harmless, in which sugar does not recur after the first weeks, and which does not show a glycosuria *e saccharo* except, perhaps, during the first weeks, and does not develop diabetes. The glucose test would, therefore, seem to give important help in differentiating these two provisional types of spontaneous glycosuria at a relatively early date." Such a differentiation is of considerable importance not only for prognosis, but also for treatment, for it is of importance that the former should be kept on a restricted diet even though the glycosuria has not recurred, while the latter need not be subjected to such restriction. K.

Treatment of Diabetes by Drugs.—Parsons (*Practitioner*, July, 1907) reviews the use of drugs in this disease under the following heads: (1) To control the glycosuria; (2) to avert or remove coma; and (3) to relieve symptoms and complications. He concludes that opium is the best anti-glycosuria drug at present available, and it is most useful in the severe cases in which a rigid diet fails to remove all sugar from the urine. Sodium salicylate and aspirin in 15 grain doses three times a day are both useful in mild cases, and jambul may be used as an alternative to either of these. Sodium bicarbonate in doses from 150 grains up, is useful to avert coma, and an intravenous injection of 35 ozs. of a 3 or 4 per cent. solution of the carbonate of soda affords the best chance of restoring consciousness in diabetic coma. Constipation should be guarded against in all stages of the disease. K.

Infantile Paralysis.—Numerous attempts have been made of late years to bring about a cure of localised paralysis due to acute anterior poliomyelitis by surgical methods. The more important of these methods have consisted of tendon transplantations and of nerve grafting. Nerve grafting has been principally carried out in cases of upper-arm paralysis, and the operation has usually consisted of implanting the diseased trunk of the brachial plexus into a neighbouring healthy trunk. Babcock now reports a case in which a novel method was adopted (*Journ. of Amer. Med. Assoc.*, Vol. 48, No. 21, p. 1742), to which he applies the term of transbrachial anastomosis. The case was that of a boy, æt. 4, who suffered from very extensive paralysis of the right arm, and also of the trapezius muscle. Owing to the extent it was found impossible to perform the more usual operations, and in consequence both brachial plexuses were exposed and a bundle of healthy nerve fibres was separated from the sixth left cervical trunk and cut across. A tunnel was then bored between the anterior muscles of the neck and the trachea, and through this the bundle was brought across the neck to be sutured to the distal end of the atrophied right sixth cervical trunk. The child was seen three and a half months after the operation, and it was then found that the left arm had not suffered in any way, and that the right arm was considerably improved, the scapular muscles, the pectorals, and the extensors of the fingers showing most beneficial change. The writers discuss the way in which the improvement may have taken place, and suggest the following: (1) That the splitting of nerve trunks reduces the pressure in individual nerve fibres, thus enabling compressed fibres to again functionate. (2) That in splitting of nerve trunks many fibres must necessarily be cut. Some of these cut fibres may be normal and some degenerated; if then new anastomoses occur, function might be partially restored to paralysed parts. (3) That new fibres actually grew from the left brachial plexus into the right. This they regard as the most likely explanation of the improvement in this case. M.

Treatment of Gastric Adhesions by Fibrolysin.—As is well known, Hebra demonstrated some fifteen years ago that thiosinamine was an agent capable of softening cicatricial tissue. The drug, however, never came into extensive use, owing to its general insolubility, and owing to the pain caused by its hypodermic use. Mendel has, however, succeeded in combining a molecule of thiosinamine with half a molecule of sodium salicylate, and producing a soluble substance, to which he has given the name of fibrolysin. This drug has the same action on scar tissue as thiosinamine, and is quite painless when given intravenously or hypodermically. Herschell has employed this drug in cases of dyspepsia resulting from gastric adhesions (*Folia Therapeutica*, No. 3, 1907, p. 85). He points out that in many cases of chronic dyspepsia there is a history suggesting the previous existence of ulceration, and that sometimes even pyloric thickening can be felt. The fibrous tissue which causes such thickening and the fibrous tissue that necessarily results from the healing of ulcers may, he thinks, be the site and cause of the pain complained of, and he believes that many cases would be improved if such tissue could be softened and the strictured pylorus dilated. To enable the stricture to be dilated he has employed Zabludowsky's gastric massage, and also electricity, with the object of improving the general tone of the stomach musculature. To soften the scar tissue he has given hypodermically fibrolysin and reports some successful cases. In three cases all pain disappeared after from twelve to thirty injections. In other cases no improvement was noted. M.

Acute Œdema of the Lung in Ether Narcosis.—Stevenson reports a case of the above indicated rare condition (*South African Med. Record*, Vol. V., No. 10). The patient was a boy, æt. 16, who was being operated on for appendicitis. He was anæsthetised with ethyl chloride followed by ether. Everything went well till towards the end of the operation, which had only lasted about forty minutes. Then respiration became hurried and difficult, and general cyanosis appeared. The diaphragm continued to contract and relax actively, while almost all movement of the thoracic muscles ceased. Auscultation at the same time demonstrated the presence of crepitations all over the lungs. Strychnine was injected, and warm applications applied to the chest, and after an hour of continued artificial respiration, improvement began, and recovery finally took place. The writer believes that the condition is due to vaso-motor spasm of the pulmonary arterioles, which embarrasses the right heart, and leads to the œdema. About ten cases have been recorded, and nine of these have died. The writer believes that the best treatment consists in the exhibition of nitro-glycerine or anyl nitrite. M.

Emotional Epilepsy.—Bratz and Leubuscher (*Deut. Med. Woch. Berlin and Leipzig*, 1907) have had occasion to observe for years twenty patients with what they call "Affekteplepsie," for which they claim a place apart. The patients have occasional attacks, suggesting *petit mal*, but with characteristics of hysteria. These attacks develop under the influence of long-continued emotional stress, and occur at times from early childhood onwards. The persons affected are always those with a neuropathic inheritance, and they are distinguished by a peculiar pallor, evidently a vaso-motor phenomenon. Like alcohol epilepsy, it never develops into genuine epilepsy. D.

Sodium Phosphate in Neurasthenic Conditions and in Exophthalmic Goitre.—Vetlesen (*Norsk. Mag. for Laeg.*, Christiana) has been proclaiming for some years the advantages of sodium phosphate in exophthalmic goitre. His later experience fully confirms his first assertions in regard to the efficacy of this remedy, which, he says, was first suggested by the success of organotherapy. He has now a record of 40 cases of exophthalmic goitre in which it has been applied. He tries it in every case, and generally derives great benefit from it. His present article relates his experience with it in neurasthenic conditions. He gives the details of 6 out of 30 cases in which he has administered it in his private practice, while it has been given to hundreds at the hospital. No by-effects were observed, but the tonic action on the nervous system was striking in many instances. He adds that the drug is a welcome addition to the usual measures at our command in treating the protean manifestations of neurasthenia. The examples he gives show marked benefit under sodium phosphate administration and its harmlessness even when continued for months. He orders one tablespoonful four times a day of a solution of 15 parts sodium phosphate in 250 parts water. D.

The Blood in Rheumatoid Arthritis.—Bullmore and Waterhouse (*Edinburgh Medical Journal*, June, 1907) have summarised the results of their observations on the blood in rheumatoid arthritis. Anæmia is almost always present in rheumatoid arthritis. There is, as rule, a slight diminution (to between 75 and 95 per cent.) in the number of the red blood corpuscles, and a slightly greater (70 to 90 per cent.) diminution in the amount of hæmoglobin. In the great majority of cases, the leucocytes are not increased in number, and the normal proportions of the different varieties to one another are preserved. Myelocytes in small numbers are present in a few cases only. D.

Lactic Acid Bacilli to Combat Intestinal Fermentation.—Dunn (*Archives of Pedriatics*, New York, April, 1907) pasteurized buttermilk, then inoculated it with a pure culture of lactic acid bacilli, allowing the mixture to ripen until the development of the organism had brought about the proper acidity and precipitation of the casein. In the majority of the cases the buttermilk was given only after all ordinary and routine measures had failed. Of 35 selected cases, there was evidence of a favourable result in 23; in 3, there was immediate cessation of diarrhœa and favourable change in the character of the dejecta, without gaining weight; in 9, no effect was produced. In 14 resistant cases of the fermentative type, the buttermilk was first given in the pasteurized form, and after a sufficient trial had demonstrated a failure to improve, the pasteurization was omitted. Immediate improvement followed in each case. In 4 cases of acute diarrhœa the only treatment was the administration of unpasteurized butter-milk. No castor oil or calomel, no bismuth or irrigations, and no period of starvation were employed. Two of these cases were successful; one patient improved slightly, and one case was a failure. Dunn says that the only conclusion that may safely be drawn from this study is that the use of living lactic acid bacilli is a harmless method of treatment, and that it may do good in cases of intestinal fermentation. He promises to investigate further and report later. D.

Derbyshire Royal Infirmary—New Medical Appointments.

At a special meeting of the governors of the Derbyshire Royal Infirmary held a few days since, Mr. R. Knowles, the president, in the chair, the Weekly Board recommended a number of alterations of rules, the most important being the appointment of an honorary pathologist. For some years past the policy of the governors had been to specialise the different departments of the institution. That was being done in other institutions throughout the country, and it was unquestionably the proper policy to pursue. The Board thought the time had arrived when they should bring this work under the supervision of one gentleman, who would attend to both the medical and surgical sides. They also suggested the appointment of a pathologist as a saving of time and money. Other proposed alterations had to do with the medical staff in regard to the restriction of voting, &c., the idea being to divide them into seniors and juniors, who should serve on the Elective Committee for appointment of paid medical officers, but in other appointments only the senior section should act. Sir Arthur Heywood, in expressing his approval of the policy of the Board said they were only copying the practice of the best hospitals in the country. The motion was carried.

MEDICAL NEWS IN BRIEF.

The King's Visit to Ireland.

DURING the past week their Majesties paid a brief visit to Ireland for the purpose of seeing the International Exhibition which is now in full swing. Although the time at his Majesty's disposal was so limited, he was graciously pleased to accept addresses from many public bodies, amongst whom were the Royal College of Physicians, the Royal College of Surgeons, and the Apothecaries' Hall. The address presented by the last-named body was as follows:—

"To His Most Excellent Majesty Edward VII. of Great Britain and Ireland, and the British Dominions beyond the Seas, King, Defender of the Faith, and Emperor of India, and His Most Gracious Consort Queen Alexandra,—May it please your Majesties, We the Governor, Deputy Governor, and Court of the Apothecaries' Hall of Ireland, representing a large and important branch of the Medical Profession, and one of the oldest qualifying bodies in this country, respectfully render to your Majesties our loyal and hearty greeting and welcome on your visit to our shores. May God Who has so abundantly blessed your reign, and given us in you a bright example of all that is good and benevolent, vouchsafe to your Majesties His best gifts, and His continuing protection. We bid your Majesties a most grateful welcome, and we fervently pray that your visit may be a happy one, and leave nothing but most pleasant memories.—We are your Majesties most humble, dutiful and faithful subjects, F. G. ADYE-CURRAN, Lieut.-Col. F.R.C.S., J.P., Governor; GEORGE SEYMOUR STRITCH, L.R.C.P. & S., J.P., Deputy-Governor; H.W. MASON, L.R.C.S.I., Secretary.

Davos Sanatorium.

A SATISFACTORY report in connection with the Queen Alexandra Sanatorium at Davos Platz, was presented at the recent annual meeting of supporters, under the chairmanship of Lord Burghclere. The object aimed at is to provide a cheap sanatorium in an alpine climate for consumptive patients of small means belonging to any English-speaking nationality. The report stated that a sum of £5,264 18s. [illegible]d. was raised last year—the largest received in any one year since the start of the fund. This gratifying result was due to a special appeal made by the president, Lord Balfour of Burleigh, in Scotland, and to a bazaar held at Davos.

The chairman, in moving the adoption of the report, said at the present time the Council had in hand nearly £20,000, but they required £15,000 more before they arrived at the goal of their hopes. They had been able to commence building, and expected that the roofing would be completed during the present season. All the expenses up to this point would be paid for out of funds in hand. They aimed at having sixty beds, at making the sanatorium completely self-supporting, and at keeping the fees as low as possible, say, a guinea and a half a week, or at most 35s. They intended it to be under English management, and for English-speaking patients alone, and they had no wish that it should be a rival to the excellent sanatoria which now existed in this country, but rather to act as a help and necessary adjunct. The battles against disease and suffering were the crusades of the twentieth century, and no one had preached these holy wars more effectively, or led them with greater influence, than their Majesties the King and Queen, to whose patronage the Queen Alexandra Sanatorium owed a deep debt of gratitude.

Mr. E. C. Simmons seconded, and the report was adopted. The council were unanimously re-elected.

Royal Hospital for Incurables, Dublin.

THE annual meeting of the Royal Hospital for Incurables, Dublin, was held on Thursday, the 4th inst., at the hospital, the Chairman, Mr. William Fry, presiding. The annual report stated that there are in the hospital 213 beds, and during the year the average daily number occupied was 210, being the largest amount of relief afforded for a number of years. Eight elections were held during the year, 162 candidates applied for admission, and 47 were elected—18 suffering from consumption, 8 from cancer, 8 from paralysis and nervous diseases, 5 from heart disease, 4 from rheumatism and arthritis, the remaining four being afflicted with various other forms of incurable disease. The number of deaths (40) is the lowest on record since 1889, when the hospital was considerably smaller than at present.

The following resolutions were adopted:—(1) "That this hospital is worthy of the public support." (2) "That the best thanks of this meeting are due, and are hereby tendered, to the citizens and other supporters who have hitherto aided the good work carried on in this noble institution."

The speakers included the Chairman, Sir John Nutting, Sir Thornley Stoker, Sir J. W. Moore, Dr. Finney, Mr. L. Malone, and Alderman Lyon.

Royal College of Surgeons.—Fellowship Examination.

NOTICE is hereby given that on and after January 1st, 1910, all Examinations for the Fellowship of this College will be conducted under the Scheme of Examination now known as Grade I. No candidate after above date will, under any circumstance, be admitted to examination for the Fellowship of this College under the scheme now known as Grade II., which will then cease to be used.

University of Birmingham.—Dental Department.

THE Council of the University of Birmingham have appointed Mr. Alfred William Wellings, B.D.S.Birm., L.D.S.Edin., as Lecturer in Dental Histology and Dental Pathology in place of Mr. H. P. Pickerill, M.B., B.D.S.Birm., who has been appointed Director of the Dental Department of the University of Otago, New Zealand.

Doctor's Suicide.—Remarkable Evidence in the Heanor Case.

THE inquest on the body of the late Dr. P. S. Harris, who was found shot in his lodgings on July 1st, was held by the District Coroner. Some remarkable evidence was given by Dr. Eames, with whom the deceased had been an assistant for the past five years. Asked by the Coroner if he had noticed anything peculiar about him of late, the witness said the deceased had been addicted to drink. Witness said that the previous Tuesday the deceased had eighteen or twenty patients to see. The next day witness found he had only seen four people, and when asked for an explanation he made answer, "I went to bed." Witness told him that would not do, and that he could not stand it much longer. The same evening a telephonic message came from Codnor to attend an urgent case whilst witness was away at another case. The deceased refused to answer the telephone, and said he would not go. Witness on his return sent him his notice of dismissal, telling him to go at the end of the week, and enclosing a cheque for work done. Subsequently witness gave him permission to stay on until the 18th, telling him he would do the best he could for him to obtain another situation. Witness wrote giving him permission to stay on condition that he became a teetotaller, adding that if he continued on his present course he would soon go to the dogs. Proceeding, witness recalled one or two incidents that would seem to point to the giving way of the deceased's mind. Witness was now satisfied that the deceased was not himself during the past week. He had heard of him telling patients that he was being persecuted and poisoned. Witness went on to depose to the injuries sustained by the deceased. There was evidence, he said, of three distinct attempts having been made on the man's throat. Tremendous force must have been used.

Another witness was Mrs. Moore, the deceased's landlady. She spoke to a conversation with the deceased late on Saturday evening. Dr. Harris then asked her what the people outside the windows were talking about him for. Witness told him that nothing of the kind was taking place. Describing the finding of the body, witness stated that when she could obtain no reply, she opened the bedroom door, and saw the deceased, partially dressed, lying in a pool of blood across the bed. He had the razor (produced) in his hand, and his head was nearly severed. She raised an alarm, and assistance promptly arrived.

Was he in the habit of taking more than was good for him ?—Sometimes.

During the past fortnight ?—He took middling, but I've never seen him drunk.

Had he seemed strange in his manner lately ?—I've noticed bits of things about him. Once he told me he had had a letter from his brother in Canada, and that it had upset him.

Did he ever threaten to do away with himself ?—No.

By the Foreman : Deceased lay on the bed wearing his trousers, shirt, and socks. He had pushed the bedclothes on one side, and had turned up both shirt sleeves.

Dr. Eames : You told me yesterday you had a terrible job with him the night before.

Witness : He said there was someone talking about him outside ; he said there was a scandal, and he would have a stop put to it.

By the Coroner : There was not a better conducted gentleman anywhere, and a nicer man in the house could not be wished.

The coroner having summed up, the jury found that the deceased committed "Suicide whilst of unsound mind."

PASS LISTS.

Royal College of Surgeons in Ireland.—Summer Session, 1907.

Barker Anatomical Prize.—£31 10s., G. S. Levis.

Carmichael Scholarship.—£15, J. Menton.

Gold Medals in Operative Surgery.—P. G. M. Elvery and T. Sheeley (equal).

Stoney Memorial Gold Medal in Anatomy.—Miss I. M. Clarke and G. C. Sneyd (equal).

Practical Histology.—F. W. Warren, First Prize (£2) and Medal ; J. S. Pegum, Second Prize (£1) and Certificate.

Practical Chemistry.—H. C. Gilmore and J. Kirker (equal), First Prize (£2) and Medal.

Public Health and Forensic Medicine.—H. Hunt, First Prize (£2) and Medal ; Miss C. F. Williamson, Second Prize (£1) and Certificate.

Materia Medica.—J. Menton, First Prize (£2) and Medal ; Miss C. F. Williamson, Second Prize (£1) and Certificate.

Biology.—J. T. Duncan, First Prize (£2) and Medal ; P. V. Crowe, Second Prize (£1) and Certificate.

The lectures and practical courses of the Winter Session will commence on Tuesday, October 15th.

Royal University of Ireland.

The following candidates have passed the undermentioned examinations :—

The First Examination in Medicine.—Christopher Barragry, Daniel J. Barrett, John L. Brown, Peter A. Clearkin, Maurice J. Cogan, Ernest J. Colgan, Patrick J. Corcoran, John F. Craig, Thomas P. Davy, Joseph C. Denvir, Bernard Doyle, B.A., Gerald Fitzgerald, Thomas F. S. Fulton, Michael J. Gallagher, Joseph Gorman, M.A., Thomas D. Graham, Gerald S. Harvey, James Hill, Joseph O. Hodnett, Norman L. Joynt, Francis J. Keane, James J. Keirans, John L. Kilbride, James Laverty, Hugh T. S. McClintock, Robert J. McConnell, Laurence J. J. McGrath, Michael McGuire, Aloysius D. MacMahon, Robert C. McMillan, Daniel McSparron, Cornelius Martin, William Megaw, William M. Millar, Alexander G. Mitchell, John J. H. Mitchell, Henry H. Mulholland, Henry J. V. Mullone, Daniel O'Brien, John P. O'Brien, James O'Connor, Thomas F. O'Donoghue, William M. O'Farrell, Joseph A. O'Flynn, Patrick J. O'Grady, Oriel J. O. O'Hanlon, Hugh O'Neill, Joseph Patrick, Joseph Porter, Joseph H. Porter, James M. Rushworth, Walter N. Rushworth, Maurice J. Roche, John M. Rowe, Hugh A. Skillin, Thomas Smyth, Francis J. D. Twigg, William Wilson.

The following candidates may present themselves for further examination for honours. Those qualified in two or more subjects may present themselves in all :—

Daniel J. Barrett, Ernest J. Colgan, Thomas P. Davy, Joseph C. Denver, Bernard Doyle, B.A., Gerald Fitzgerald, Gerald S. Harvey, Joseph O. Hodnett, Norman L. Joynt, Francis J. Keane, James J. Keirans, Robert J. McConnell, Michael McGuire, Aloysius D. MacMahon, Daniel McSparron, William McGaw, William M. Millar, John J. H. Mitchell, Henry J. V. Mullone, Hugh O'Neill, Joseph Patrick, Joseph H. Porter, James M. Rushworth, Hugh A. Skillen, Thomas Smyth, William Wilson.

Trinity College, Dublin.

The following passed the Intermediate Medical Examination during Trinity Term, 1907 :—

Part I.—Adrian Stokes and Charles M. Finny, passed on High Marks.

The following names are arranged in order of merit : Marius A. Diemont, Hilgard Müller, Roclif A. Albertyn, Vicars M. Fisher, Beatrice M. Hamilton, Perceval G. Leeman, Victor G. Best, David Duff (Sch.), John H. Woodroffe, Edmund F. Lawson (Sch.), John G. Ronaldson, Arthur C. Hallowes, Benjamin A. Molyneux, Louis Trichard, John G. Dods, Edward P. Allman-Smith, Edwin B. Bate, Brinsley H. Moore, Charles Pentland.

Part II.—Albert J. Stals (passed on High Marks), John D. Kernan, Cecil P. Smyly, David Duff (Sch.), Benjamin A. Molyneux, Edwin B. Bate, Alexander K. Cosgrave, Louis Trichard, Hugh S. Metcalfe, William A. Nicholson.

Preliminary Science Examination.—Physics and Chemistry.—Bernard G. Quinlan, Ronald G. M'Entire, Henry L. W. Woodroffe, Patrick Murphy, James M. Elliott, Thomas G. Harpur, Arthur Chance, Edgar Ll. F. Nash, Thomas L. Bookey, Francis C. Crosslé, Arthur F. Shaw, Leonard Shiel, Osward C. Tandy, Edward H. H. Lloyd-Dodd, Francis Breen, Albert E. Malone, George M. Maybury, Robert W. Murphy, Hugh E. Williams, Hugh M'C. Fleming, Matthew M'Knight, James C. Kelly, Andreas A. Louw, Robert C. M'Kelly, Humphry L. Blackley.

Botany and Zoology.—Henry L. W. Woodroffe, Arthur F. Shaw, Francis C. Crosslé, Thomas G. Harpur, Georgina Revington, Hubert T. Bates, Eileen M. Hewitt, Frederick B. M'Carter, Gerald G. P. Beckett. (The former passed on High Marks.) Dorothy K. Milne, Francis Usher, Percy D. Long, Robert W. Murphy, John T. Higgins, Thomas King-Edwards, Henry S. Champion, Arthur Chance, Marjory Chapman, Francis T. G. Corscadden, Richard Grandy, Richard P. Pollard, James N. G. Nolan, Cecil Rutherford, Brian D. Crichton, Bernard G. Quinlan, Robert G. Ball.

The following candidates passed the Final Medical Examination, Part I. :—

*Johannes C. Pretorius, *John A. W. Ponton, *Richard P. Hadden, Henry H. Ormsby, Charles W. Laird, Albert, E. Wynne, William E. Hopkins, Samuel F. Charles, Frank Smartt, David G. Madill, Albert V. J. Richardson, James F. Clarke, George Halpin, Herbert V. Stanley, Gerald G. Mecredy, Dixie P, Clement, Arthur H. Laird, George B. M'Hutchison, Ernest C. Lambkin, Alexander S. M. Winder, James P. S. Dunn, Norman P. Jewell, William H. M'Carthy. (* Passed on High Marks.)

The Medical Travelling Prize was awarded to Robert E. Wright.

The Medical Scholarships in Anatomy and Institutes of Medicine to Adams A. M'Connel (Trinity) and Thomas A. Hughes (Stewart).

Prizes in Physics, chemistry, Botany, and Zoology to Henry J. Smyly (Trinity) and Herbert de L. Crawford (Stewart).

The Purser Medal in Institutes of Medicine to Charles M. Finny.

Previous Dental Examination : Anatomy and Institutes of Medicine.—George Elliott.

Physics and Chemistry.—Arthur A. Campbell and Kenneth C. MacNaught.

NOTICES TO CORRESPONDENTS, &c.

☞ **Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.**

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies. Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

M.R.C.S.—The question of a doctor's degree for the London student is a very old one, and as long ago as 1885, at a meeting of Fellows of the Royal College of Physicians of London, a resolution was passed by a large majority stating that it was desirable that students examined by the Royal College of Physicians of London and the Royal College of Surgeons of England conjointly, and found duly qualified, should, in virtue of such examination, have a degree in medicine or surgery conferred on them.

G. P. (Norwich).—All we can say is that as yet no one knows. A locum—provided his emoluments (i.e., salary, board and lodging) do not amount to £5 a week—would most probably be considered a workman, and the principal consequently liable for accident, although the engagement was a temporary one. As compensation can be obtained for so small a sum, it is certainly wise to insure with a sound office. But we agree it is hard lines. Unfortunately, ignorance of law is no excuse.

Omicron.—We cannot bring ourselves to believe that the facts are as stated, and certainly could not take the responsibility of advising on them unless very good evidence of the occurrence were forthcoming. The hospital has a high name and the staff consists of gentlemen of reputation, so we should advise you to verify the patient's statement very carefully before committing yourself. If anything further comes to light, we should be glad to hear.

A Layman.—Your communication came to hand as we were "at press"—too late to be dealt with in present issue.

Meetings of the Societies, Lectures, &c.

Wednesday, July 17th

Medical Graduates' College and Polyclinic (22 Chenies W.C.).—4 p.m.: Mr. J. Berry: Clinique. (Surgical.)

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—2.30 p.m.: Skin (Dr. Meachen), Eye (Mr. Brooks), Medical Outpatient (Dr. Whipham).

Thursday, July 18th.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical).

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques:—Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson). 3 p.m.: Medical In-patient (Dr. Chappel).

Hospital for Sick Children (Great Ormond Street, W.C.)—4 p.m.: Lecture:—Mr. Lane: Fractures.

Friday, July 19th.

Society for the Study of Disease in Children (11 Chandos Street, Cavendish Square, W.).—5 p.m.: Annual General Meeting.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—9.30 a.m.: Clinique:—Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. Leslie).

Vacancies.

Bradford Poor Law Union.—Resident Assistant Medical Officer. Salary, £100 per annum, with rations, apartments, and washing. Applications to George M. Crowther, Clerk to the Guardians, Union Offices, Manor Row, Bradford.

Cancer Hospital (Free).—Two Assistant Anæsthetists. Applications to Fred, W. Howell, Sec. (See advt.)

Liverpool Infirmary for Children.—House Surgeon. Salary, £100 per annum, with board and lodging. Applications to Arnold J. Cleaver, Hon. Sec., Liverpool Children's Infirmary, Myrtle Street, Liverpool.

Middlesex Hospital, W. (Cancer Department).—Medical Officer and Registrar. Salary, £100 per annum, with board and residence. Applications to F. Clare Melhado, Secretary-Superintendent.

Rotherham Hospital and Dispensary.—Senior House Surgeon. Salary 110 per annum, with rooms, commons, and washing. Applications to the Secretary, H. Kelson, Masonic Buildings, High Street, Rotherham.

Royal Halifax Infirmary.—Second House Surgeon. Salary, £100 per annum, with residence, board, and washing. Applications to Oates Webster, Secretary, Royal Halifax Infirmary.

Royal Albert Hospital, Devonport.—Resident Medical Officer. Salary, £100 per annum, with apartments, board, fuel and lights, and laundry. Applications to the Chairman of the Selection Committee.

Stockport Union.—Stepping Hill Hospital.—Resident Assistant Medical Officer. Salary, £130 per annum, with furnished apartments, rations, etc. Applications to Charles F. Johnson, Clerk to the Guardians, Union Offices, Stockport.

Taunton and Somerset Hospital.—House Surgeon. Salary, £100 per annum, with board, lodging, and laundry. Applications to Reginald A. Goodman, Secretary, 3 Hammet Street, Taunton.

The Hospital for Sick Children.—House Physician, House Surgeon, Assistant Casualty Officer. Dates and particulars of Stewart Johnson, Sec. (See advt.)

West Ham Union.—Medical Superintendent of Infirmary. Salary, £700 per annum, with unfurnished house, light, and coal. Applications to Alfred Hall, Acting Clerk, Board Room, Union Road, Leytonstone, N.E.

West Bromwich District Hospital.—Senior House Surgeon. Salary, £110 per annum, with board, residence and laundry. Applications to T. Foley Bache, Esq., Churchill House, West Bromwich.

Appointments.

Beatty, W. J., L.R.C.P.Edin., L.F.P.S. Glasg., by the Home Secretary H.M. Referee and Judges' Assessor under the Workmen's Compensation Act (1906) for County Court Circuit 15.

Bennett, T., M.B., B.S.Glasg., Certifying Surgeon under the Factory and Workshop Act for the Knaresborough District of the county of York.

Coates, F. A., L.R.C.P.Lond., M.R.C.S., Certifying Surgeon under the Factory and Workshop Act for the Whitchurch District of the county of Hants.

Corbett, Catharine L., M.B., Ch.B.Vict., Junior Assistant Medical Officer at West Ham Union Infirmary.

Fawcett, W. H., M.D.Brux., M.R.C.P., F.R.C.S.Edin., D.P.H.Lond., Assistant Physician to the Royal Victoria Hospital, Bournemouth.

Good, Arnold Saxty, L.R.C.P.Lond., M.R.C.S., District Medical Officer by the Torrington (Devon) Board of Guardians.

Goodwyn, Henry, L.R.C.P. and S., L.M.Edin., Medical Officer for the Bovey Tracey District by the Newton Abbot (Devon) Board of Guardians.

Hayes, H. W. McCaully, M.R.C.P.Edin., L.R.C.S.Edin., L.F.P.S.Glasg., Chief Medical Officer of the South Indian Railway, India.

Johnson, J., L.R.C.P. and S.Edin., L.F.P.S.Glasg., Certifying Surgeon under the Factory and Workshop Act for the Blackpool District of the county of Lancaster.

Mitchell, E. J. D., M.A., M.B., B.C., has been appointed Casualty Officer at St. John's Hospital for Diseases of the Skin, Leicester Square.

Morgan, James Arthur, L.R.C.P.Lond., M.R.C.S., L.S.A., Medical Officer of Health for the Llanwrtyd (Breconshire) Urban District.

Nelson, W. E., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Act for the Henley-in-Arden District of the county of Warwick.

Richards, Thomas Edward, M.B., C.M.Edin., Medical Officer and Public Vaccinator for the Ystradgynlais District by the Ystradgynlais (Breconshire) Board of Guardians.

Births.

Keeling.—On July 12th, at Market Bosworth, Nuneaton, the wife of Hugh N. Keeling, M.R.C.S., L.R.C.P., of a daughter.

Loudon.—On July 5th, at Linwood, Hamilton, Lanarkshire, the wife of J. Livingstone Loudon, M.D., D.P.H., of a son.

Newnham.—On July 10th, at 3, Lansdown Place, Victoria Square, Clifton, the wife of W. H. C. Newnham, M.A., M.B., M.R.C.S., of a daughter.

Worthington.—On July 10th, at Hurst House, Chesterfield, the wife of Sidney Worthington, M.D., of a daughter.

Marriages.

Bentham—Hall.—On July 9th, at the Parish Church, Weddington, Selina Points (Lina), youngest daughter of the late Rev. Bracebridge Hall, to the Rev. Walter Reid Bentham, youngest son of S. Bentham, M.R.C.S., L.S.A., of Hampstead.

Brownlie—Walker.—On July 11th, at the Parish Church, Saltburn-by-the-Sea, Alexander Brownlie, M.D., of Redcar, to Mabel, youngest daughter of William Walker, of Saltburn, Yorkshire.

Glanville—Bell.—On July 11th, at Hampstead Parish Church, William M. G. Glanville, M.B., B.Ch.Oxon., of Hampstead, to Muriel, eldest daughter of Edward Bell, of Hampstead.

Patmore—Scott.—On July 13th, at St. James's Church, Piccadilly, London, John Deighton, son of Dr. T. D. Patmore, to Ethel Elizabeth, daughter of James H. Scott, of Kenwyn, Leigham Court Road, Streatham.

Payne—Wise.—On July 9th, at St. Chad's, Shrewsbury, Otto Vaughan Payne, M.B., B.C., of Northwood, Alton, Hants, second son of the late W. G. Payne, F.R.C.S., to Eleanor Beatrice, younger daughter of the late D. R. Wise, of Murivance, Shrewsbury.

Deaths.

Bentham.—On July 10th, at Manchester, suddenly, of cerebral hæmorrhage, Samuel Bentham, M.R.C.S., L.S.A., of The Limes, S. Hampstead, aged 84 years.

Osgood.—On July 10th, at 165, Woodstock Road, Oxford, Hamilton Osgood, M.D., of Boston, U.S.A., in his 69th year.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXV. WEDNESDAY, JULY 24, 1907. No. 4

NOTES AND COMMENTS.

The Other Side of the Lantern.

AT Liverpool quite recently was held the fourth annual meeting of the British University Students' Congress, at which the dumb animal that is accustomed to being led to the slaughter of examination found both voice and audience. In the report furnished us we do not find how many students were present or were represented, but from an appended account of an Athletic Gymkhana which followed the more serious proceedings, we gather that a great many of the students were of the fair sex. The latter entertainment seems to have been a blithesome affair, the names of ladies and gentlemen being bracketed together in any number of events, but no doubt this light-heartedness was due to the elation of having in the morning disposed by unanimous resolution of some of the great problems of medical education which cause their pastors and masters so much heart-burning. But whether strictly representative or not, and even if one sex were present in undue proportion, it cannot but be interesting and instructive to hear what is thought in student-circles with regard to the course their examinations should pursue. The motion that will have most interest for medical men is one proposed by Mr. E. Darwin Wilmot, of Edinburgh, to the effect that the present lack of uniformity in medical examinations in the British Universities is detrimental to the progress of medical education; that it is desirable to establish uniformity, both in the grouping of subjects for examination and in the standard of knowledge required; and also that a State Examining Board should be appointed to control examinations.

Medical Socialism and Medical Imperialism.

THE object of this proposal, according to the supporters, was to get rid of anomalies in teaching, and also to allow students to pass freely from one University to another at any point in their career when they wished to avail themselves of any specially coveted teaching. Mr. Wilmot stated that the system of examination by the State is working satisfactorily on the Continent, and he wanted all the Colonial universities also standardised, till they came into conformity with English universities; indeed, "he would like to see the whole Empire united in one big medical school." Now although State examination is the natural corollary of State registration of medical practitioners, and the "one-portal" system is the ideal, the curious combination of medical socialism and medical imperialism suggested by this resolution—which was passed by the Students' Congress—seems to have the defects of both its qualities. If there is one good feature about university training it is that it turns out men of a certain stamp, and the competition to turn out those of the best and most successful stamp is highly advantageous. On the other hand, though it is doubtless a good thing for the young Britisher to know something of the Colonies, it is hardly likely that the bonds with the Mother Country would be cemented by turning the Empire into one vast medical school. Moreover, though it is a capital training for him to exercise his originality, the general experience of older people is that the student is eminently improved by a little healthy discipline, and if he could migrate swallow-like from one university to another as the fit took him, the salutary rigour of control would be in danger of becoming emasculated. If a student goes to a good medical school or university and partakes of its *esprit de corps*, he is likely to be better prepared for the battle of life than by leading a nomad existence in places he found pleasant.

Medical Referees and the Home Office.

Now that the Home Secretary has published the full rules and orders for the working of the Workmen's Compensation Act, 1906, as affecting the medical aspects of the points that arise under it, we are glad to be able to say that these regulations are less unfavourable than we understood them likely to be. With regard to fees to medical referees, it certainly is a sign of grace to be noted and to be thankful for that the fees for consultation have been fixed at what may be termed market-rates, that is to say, two guineas for a referee's opinion in an ordinary case, and a guinea for any supplementary report with regard to the same accident. For this sum the referee must be prepared to go any distance within two miles of his house, and for further distances he is to be given certain allowances which do not err in the direction of generosity, namely, five shillings a mile beyond two and up to ten, and a shilling a mile beyond ten. As, however, a county court district or sub-district is not a very large area, we imagine that hardship under these regulations is not very probable. The bad feature, as we conceive it, is that in the usual way the registrar of the County Court is to be the authority to decide whether a referee should be employed. Difficult situations of many kinds are likely to arise in connection with placing patronage of this kind in the hands of minor officials, and we see many elements of trouble in the arrangement. Moreover, red-tape checks and hindrances of many kinds are provided to waste time, multiply clerical work, and provoke tempers.

The Official Mind. The official mind is a curious example of how the maximum of training can produce the height of ineptitude, and it certainly is one of the blessings of the British constitution that it puts the civil service directly under Parliament, and therefore more or less in touch with the nation. The object to aim at in working a Compensation Act involving a large number of small claims should be two, namely, that the genuinely-injured workman should get his money with the least possible trouble and, secondly, that the malingerer should speedily find it was no good trying to get any at all. The more obstructive the machinery for carrying out the act, the more trouble and expense will the genuine workman have—expense which will speedily obliterate the few pounds he may be entitled to—and the more chance will rogues have of getting a week or two's wages to which they are not entitled. In the vast bulk of cases under the new Act the sole questions will be the medical ones: Is the workman disabled? And how long is he disabled for? An authoritative referee who was readily available could decide the points quickly enough in most instances, but, as it is, the registrar is only likely, in view of the fee payable, to refer to him after much delay, during which the honest will suffer and the wicked triumph. We shall be glad to hear how the new administration pans out in different parts of the country; the working of the last two acts was admittedly a clumsy failure.

Whooping-Cough Parties. *Ex America semper aliquid novi.* The extravagances of wealth have nowhere been so ostentatious as in America, a country in which mountainous fortunes and sportive imagination are wont to riot. The smaller fry take their tone from the wealthier classes and frequently ape their oddities while they do not possess their wealth. The "freak" dinners that were lately the rage in the more vulgar coterie of millionaires have, it is reported, their counterpart at Pittsburg in what may be termed pathological parties. It seems that in that city of steel an epidemic of whooping-cough is about at the moment, and as the sufferers are able to go about, and yet are tabooed by their friends, a certain lady who with her son is suffering from the disease, gave a "whooping-cough *fete*" lately to her fellow-patients. By way of entertainment, a competition was organised for those who whooped the loudest and the longest, and similarly, consolation prizes were offered for those who had the feeblest paroxysms. We should hope that the better public opinion in America would join with us in reprobating so disgusting an outrage on good taste.

On July 12th, at a meeting of the Central District Committee of Stirlingshire County Council, the Medical Officer made a statement with reference to the serious epidemic of enteric fever in the villages of Plean and Cowie. There had up to the present been seventy-six cases and seven deaths, and in his opinion the outbreak was due to infected milk from a farm. The frequent rains of the past few weeks had had a salutary effect by laying the dust between the rows of houses and keeping down flies in the houses and ashpits. The fever was now abating.

LEADING ARTICLES.

HOSPITAL FUNDS AND LOCAL HOSPITAL PRACTICE.

The question of the allocation and conditions of tenure of hospital appointments is clearly one of vital importance to the medical profession. If lay bodies assert their right to control and regulate the terms of medical staff appointments it seems a self-evident proposition that they should make sure of their ground before proceeding to take any active steps in the matter. The hospital funds occupy the position of trustees in charge of a distributing agency, but to that function they have added other claims of a remarkable nature as regards hospital administration. While few persons would question the desirability of having some sort of responsible control of the financial and administrative management of medical charity, it is, nevertheless, an entirely different thing when a Fund threatens the existence of a given hospital by denying a grant upon grounds that are arbitrary and unascertainable. The policy of the Sunday and the King Edward VII. Funds is in the hands of a group of non-representative men who have their own peculiar views upon the way sums of money should be granted and of what should be the professional status and qualifications of members of medical staffs. Take the question of amalgamation of hospitals. Three orthopædic hospitals, as we have previously insisted, were forced to amalgamate in spite of the disadvantageous sale of one enormously valuable site in Oxford Street. The Funds have permitted the charter of the amalgamated institutions to exclude Scotch and Irish diplomates from their medical staffs, in spite of the fact that two of the joining hospitals were open to gentlemen who had gained their theoretical surgical knowledge outside London. In this particular matter we hold that the Funds which urged amalgamation and did not provide against the disqualification mentioned, departed from the high standards of justice and broad-mindedness that should characterise great public bodies of the kind. We venture to say that such an indignity would not have been imposed upon Scotch and Irish diplomates had the public, the medical staffs, general practitioners and the hospitals themselves been properly represented on the management of the Funds. It is difficult to understand the frame of mind that can lead an executive of amiable philanthropists to imagine themselves gifted by a sort of divine right to control a vast number of tangled lay and professional interests. It was only at the last moment that Parliament woke up to the facts of the situation and modified the autocratic powers that were sought in the King's Fund Charter Bill. That the sphere of the Fund's activities is to be considerably extended seems clear from the action of the King Edward Fund with regard to the Hampstead Hospital. That institution afforded an admirable example of a first-rate hospital officered by local medical men. It was popular amongst its supporters, no less than amongst its patients and medical men in the neighbourhood. The King Edward Fund, however, formed a theory that the local practitioner should be replaced by consultants and that to permit this the hospital should be amalgamated with the North-West London Hospital. With regard to the amalgamation proposal from the financial aspect we have nothing to say at present, but the proposed exclusion of local practitioners from the hospital they have, so to speak, created, demands the careful attention of the whole medical profession. If the experience gained in hospital be of educational value, as it undoubtedly is, why should the Hampstead inhabitants who support the hospital consent to having that advantage taken away from their own private medical attendants ? In the provinces it is the rule rather than the exception for members of hospital staffs to engage in general practice. That plan works well enough, and we have never heard it seriously asserted that the public would gain by making consulting practice a *sine qua non* for tenure of such appointments. Why Hampstead cannot be trusted to furnish a sufficient number of local practitioners fitted to attend to its sick poor is not clear. If the King Edward Fund is to alter that state of things, which so far has worked admirably, surely the medical profession, no less than the public, are entitled to have a full and adequate explanation of why the proposal is made. It may be that the King Edward Fund has an admirable and convincing case to present, but owing to its autocratic methods, no such statement has been or is likely to be issued. Indeed, as we have pointed out on various occasions, the inherent flaw of the King Edward Fund is its want of representative control. Under its present irresponsible administration its acts and motives must necessarily from time to time be called into public question, but just as often there will be no public answer, and the reputation of the Fund will in the long run be likely to suffer. In the case of Hampstead a great deal of feeling has been imported into the dispute, and however much the motives of the Fund may be above suspicion, it can hardly be gainsaid that a feeling of resentment will linger in the minds of a great many of the inhabitants who feel that their medical attendants have been slighted, and that an attempt has been made by the Fund to hand over their institution for the benefit of another hospital and of a body of consultants hailing from another district. A further aspect of the case is the hostility likely to be aroused amongst the Hampstead practitioners by what they naturally regard as an unwarrantable attack upon their existing rights. It would require a strong body indeed to go on exciting hostility in so many classes of the community. At any rate it would be well for the King Edward Fund to lay down in black and white the principles on which its grants are to be made, and whether in the future its voice is to be equally autocratic in deciding the fate of small hospitals by the withholding of grants and the enforcing of amalgamation schemes. It is not too late, even now, for the Funds to amend their constitution and to invite to their councils representatives of the small hospitals and of the medical profession generally. It should be noted by our readers that the questions involved are of universal application and that which is taking place in London to-day may have to be encountered in any part of the United Kingdom to-morrow. It will be of some interest to watch the progress of events at Hampstead, and to note what part, if any, is taken by the Medical Defence and other professional organisations whose duty it is to safeguard the interests of the medical practitioners.

CURRENT TOPICS.

Amalgamation of the Obstetrical and Gynæcological Societies.

SINCE our last issue, containing a paragraph headed, " For London or the United Kingdom ? " we have received further and more exact information with regard to the circumstances under which the amalgamation of the Obstetrical Society and the British Gynæcological Society into a section of the Royal Society of Medicine took place. It will be remembered that we were struck with what appeared to be the disproportionate representation of some parts of the United Kingdom on the proposed Council which is to be elected in October. At first sight the figures certainly invited criticism, but we are gratified to learn that a satisfactory explanation of the disparity will be forthcoming in due time, and that an entirely different complexion will be placed on the matter than that which appears at first sight. We are not at liberty at present to treat the subject as fully as we should wish, but we hope soon to be able to deal with it at greater length. The union of these two societies under the banner of the Royal Society of Medicine is an event of such happy omen that it would be a matter of profound regret were any cloud to overshadow the new order of things.

An Englishman's Breakfast.

YOUR average Englishman is proud of many things which, deep down in his heart, he regards as distinctive of his breed. In every detail of his life he worships virility, and he looks with calm distrust upon lack of lustiness in art, science, literature, commerce, politics, sport, or religion. Good brains he can hardly dissociate from good beef and beer, not to say plum-pudding and other solid fare. Above all, breakfast is to him the test-meal of the good old insular stomach, which is always in its place when wanted, a silent, unobtrusive friend that complains not, in spite of many a buffet and a whole lifetime of ill-usage. Yet Dr. Emil Reich says that the Englishman loads his stomach at breakfast with chops and bacon and eggs and other provender that he cannot digest, and the English are therefore assumed to be rapidly degenerating in mind and body in consequence of this morning gluttony. The weak link in this Teutonic chain is the assumption that our countryman, as a rule, cannot digest a heavy breakfast. If one thing more than another constitutes the birthright of all ages of Englishmen down to the days of good King Edward VII., it is the gusto with which he disposes of a huge breakfast and the solid unconsciousness of that precedent condition which blesses the later labours of his strenuous day. The Teutonic appetite that whets itself on a species of bastard bread and a cup of coffee, to the sound of melancholy music is to the Englishman an object of contemplative and never-ceasing pity. When the English breakfast becomes a thing of the past, then, indeed, may we cry aloud because of the degeneracy of our race.

Drilling in Schools.

Signs are not wanting that the hand of sanitary science is making itself felt in the regulation of schools. For instance, one of the great achievements of modern times has been the recognition of the fact that it is no use to thrust compulsory education upon starving children. One small matter seems to have hitherto escaped the notice of school authorities, namely, the undesirability of drilling children in school-rooms. The scientific facts of the situation are clear and simple. Bacteria being heavier than air, sink sooner or later to the floor of a room. From the necessary conditions of environment a school-room becomes charged from top to bottom with multitudes of bacteria of a manifold nature. If the children have to scrape and stamp the floor in various drills and other evolutions, the bacteria will be stirred up in clouds to the detriment of all concerned. The cleaner and the better-ventilated the room, of course, the less the danger. The plain fact of the matter that stares us in the face, and should be brought no less directly to the notice of all school authorities, is that school drill should take place in the open air or in a freely-ventilated drill shed.

Mr. McKenna and School Hygiene.

We hope that Mr. McKenna who is reputed to be a capable administrator and sound Parliamentarian, is not seeking to put himself out of touch with medical opinion now that he has gone to the Education Board, nor that he is, as appears in several directions, opposed to the pushing forward of school hygiene. No doubt there is little to be got out of it politically, because all corners of the House of Commons are equally set on school hygiene being pushed forward, though unfortunately, no one is so much in earnest as to give the others no peace till universal medical inspection and regulation are accomplished facts. Still, Mr. McKenna has come fresh to a series of problems which not only have troubled men's minds for years, but about which they have long been made up, and he is displaying a feeble reluctance to lead or be led. To the *Times* last week, Sir Lauder Brunton wrote an important letter pointing out that whereas Mr. McKenna has been shielding himself from the reproach of inertia behind the International Congress on School Hygiene which is to assemble in London this summer, and while he is yet talking of all that the Education Board are doing or are going to do for it, actually all that has been done officially is to appoint three semi-official delegates, pay three guineas for their tickets, and lend two unused lecture-rooms. Now it is time to assure Mr. McKenna that medical men and we believe the whole country, have made up their minds and that they do not propose to look admiringly at the Education Board or at a politician who cares for none of these things. The religious difficulty may be insoluble; the school-hygiene problem is solved. It now only awaits masterful and energetic administration to have the whole matter speeding happily on the right track. We believe that any dallying with it will cause more unpopularity to the Government than all the religious squabbles put together.

Plague in India.

The figures quoted in the House by Mr. Secretary Morley, of the mortality from plague in India, should rouse even the most callous to a sense of the responsibility of England in the government of the dependencies. From the appearance of plague in the year 1896 to May 31st last, there were 5,402,245 deaths from that disease. During the six months ending June 30th, the number of deaths was 1,060,067, being more than had taken place during any entire year hitherto. In fact, since the first appearance of the disease, it has increased in almost steady progression year by year, the only marked exception being in 1906, when the total number of deaths was just a third of a million. The present year, however, as we have seen, threatens to be by far the worst yet. In all seriousness we say that the plague in India is the gravest problem before the country at the present time. Almost a million of our fellow-subjects are dying each year of an entirely preventable disease, and the steps taken to deal with it are of little more than a perfunctory character. Public opinion shows no interest in the subject, and hardly a daily paper has commented on the appalling figures. It is hardly matter for wonder that there is unrest in India, when disease is allowed to walk unchecked through the land. "The white man's burden" must be realised as something more than a topic for jingo songs and armchair complacency. It is a real and pressing fact which must be fairly faced. We look with anxious expectation for the full account of the policy of the Government, which Mr. Morley has promised to put before the House of Commons at an early date.

Halifax Hospital Controversy Ended.

A pithy moral may be pointed from the controversy that has been going on for some time past between the Halifax Board of Guardians and the British Medical Association. Some little while since, on the resignation of their then medical officer, the guardians advertised the vacant post at a salary of £100 per annum, or a drop of £40 on that of the last occupant. A campaign was then started by the Association, and several candidates were induced to withdraw their applications, and the Halifax vacancy was posted in a medical black list. After the failure to secure an officer at £100, the guardians advertised the post again at £120. An applicant was appointed, but the Board failed to acquaint her of the opposition of the Association, and they, moreover, induced her to sign a document agreeing to fulfil her duties under a penalty. In spite of these precautions, further negotiations went on between the local medical men and the guardians, with the result that the new officer is to start at a salary of £125. This incident proves the necessity of watchful vigilance on the part of some central body as to the terms of State, Poor Law and other public appointments. It also emphasises the value of concerted action, of publicity, and of the absolute necessity of loyalty on the part of individual members of the medical profession to the principle of collective protection and self-preservation, let journalists and guardians call it trades-unionism or what they will.

An Advance in Police-court Psychology.

The humaner administration of criminal justice is becoming by slow degrees more and more apparent as the world grows older. It will be a long time, however, before the mental responsibility or otherwise of an accused person will be submitted to any skilled and impartial arbitration. Here and there a prisoner is acquitted on the score of insanity, or of suffering from what is commonly known as kleptomania. From the account of many police cases, on the other hand, it is perfectly obvious to the medical reader that the accused must have been suffering from mania with delusions or from general paralysis. We have often urged the necessity of some central authoritative body of mental experts, to whom appeal could be made in all doubtful cases, and who should exercise a further general supervision over all trials in which the evidence suggests the desirability of special enquiry. On the Brentford bench last week, the magistrate discharged a prisoner charged with theft on the report of the police surgeon that she was suffering from minor epilepsy and that during an attack she had not the slightest knowledge of what she was doing. The magistrate enquired if that state of affairs was not very unusual, but fortunately did not adopt the usual legal attitude with regard to the plea of mental irresponsibility, namely, that of assuming an explanation which is not understandable by sane standards is, therefore, false. It is to be hoped that the Brentwood decision may be taken as an encouraging sign of the times.

PERSONAL.

The King has been pleased to appoint Sir Thomas McCall Anderson, M.D., F.F.P.S., to be one of His Majesty's Honorary Physicians in Scotland, in the room of Sir Thomas R. Fraser, M.D.Edin., LL.D.

Sir Richard Douglas Powell, K.C.V.O., has been promoted from being Physician-Extraordinary to the King to be Physician-in-Ordinary, in the place of the late Sir William Broadbent.

Dr. Bertrand Dawson, Physician to the London Hospital, has been appointed Physician-Extraordinary to the King.

Dr. A. E. Boycott, M.A., B.Sc.Oxon., has been appointed Gordon Lecturer on Pathology in the Medical School of Guy's Hospital.

The address in Medicine at the meeting of the British Medical Association will be delivered on July 31st by Dr. W. Hale White, of Guy's Hospital, who will advance "A Plea for Accuracy of Thought in Medicine."

The address in Surgery has been allotted to Mr. H. T. Butlin, of St. Bartholomew's Hospital, who will deal with "The Contagion of Cancer in Human Beings, Auto-inoculation."

A popular lecture on Weather, Climate, and Health will be given by Sir John William Moore, of Dublin.

Dr. Arnold Davies, B.A. (Lond.), a member of the Livingstone Medical Missionary College, Edinburgh, has been appointed by the London Missionary Society to succeed Dr. N. C. Bentall. in India.

In the Edinburgh Royal Maternity and Simpson Memorial Hospital last week the Committee in charge of the complimentary recognition of Sir A. R. Simpson, M.D., LL.D., met the Board of Directors, and asked their acceptance of a gift of money towards the endowment of a bed.

Dr. Henry Davy, President of the British Medical Association for 1907-8, will be inducted on the 30th inst., and will deliver his presidential address on the evening of the same day, which has been fixed for the opening of the 75th annual meeting of the Association at Exeter.

On July 13th a deputation representing the Dublin Civil Service Medical Aid Association waited upon Dr. J. J. Murphy, at his residence, to present him with an address and purse of sovereigns, as a mark of the appreciation and regard entertained by that body towards him as medical officer.

Dr. August Dupre, the well-known chemist and authority on explosives died on July 16th at his residence, Mount Edgcumbe, Surrey, in the 72nd year of his age. He had been consulting adviser to the Explosives Department of the Home Office since 1893.

Professor Chrobak, of Vienna, has resigned his appointment as Director of the Lying-in Wards and the Gynæcological Clinic in that city.

Mr. R. E. Wright has been awarded the Medical Travelling Scholarship of the University of Dublin.

Dr. H. M. Woodcock has been awarded the Royal Society's studentship in biology to help him to carry out his researches into the life-history of the hæmatozoa of birds at the Lister Institute.

Mr. G. O. Whittaker presided at the North Midland Branch of the British Dental Association's recent annual meeting.

Professor Grancher, one of the most famous of French physicians, has died at Paris.

Professor Alexander Macphail, of St. Mungo's College, Glasgow, has been appointed Lecturer on Anatomy at Charing Cross Medical School.

Professor Radner is to preside at the International Congress of Hygiene to be held at Berlin in September.

A Clinical Lecture
ON
"DISORDERS OF SLEEP." (a)

By PURVES STEWART, M.D., F.R.C.P.,

Physician to Westminster Hospital, and to the Royal Orthopaedic Hospital; Assistant-Physician to the West End Hospital for Nervous Diseases.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

Most of us spend about one-third of our life in sleep, but in spite of this, the physiology of sleep is not yet completely understood. Let us recall for a moment the chief phenomena of ordinary healthy sleep. First, there is a diminution, then a loss of conscious recognition of ordinary stimuli, stimuli which would ordinarily attract our attention, whether those stimuli be derived from the outer world, or from within our own organism. There is also the characteristic but indescribable sense of well-being with which we are all familiar, just at the moment of dropping off. Consciousness becomes blunted, voluntary movements become languid, and ultimately cease, and the muscles of the limbs relax. Meanwhile, there develops a double ptosis, respiration is slowed and becomes deeper, the pulse is slowed, the cutaneous vessels slightly dilate, and the body temperature falls a little. Many processes of metabolism, especially digestion and certain secretions, are retarded. Various explanations have been offered for these phenomena. But at the outset we should recognise that sleep is not merely a function of the brain, it implicates many organs of the body. It is generally admitted that during sleep the brain is anæmic. If we take an animal or a patient who has been trephined and observe through the trephine hole during sleep, we see that the volume of the brain is diminished, that it is pale, and that the cortical vessels are contracted. This vascular constriction is not confined to the cortical vessels, for if we succeed in examining the retina with the ophthalmoscope while the person is asleep, we find in the retinal vessels a similar constriction, so that we may conclude there is, during sleep, anæmia of the whole brain. We are all familiar with the difficulty of doing severe mental work after a heavy meal, and we know the drowsiness at such times, and the tendency to fall asleep. This is probably due to temporary abdominal hyperæmia, causing a compensatory cerebral anæmia. The activity of certain nerve cells, especially those of the cortex, is temporarily diminished. Some observers a few years ago suggested that this was due to retraction of the dendrites of the different nerve cells, whereby those cells became temporarily insulated, that there was a sort of amœboid movement of retraction. But the evidence in support of this theory is by no means convincing. In fact, modern histological observations show that the nerve cells are not anatomically independent. Other observers attribute the phenomena of sleep to poisoning of the nerve cells by the accumulation of CO_2, or to some toxic waste products of metabolism, which act as narcotics. This may be so to some extent, but it has been shown that neither CO_2 poisoning nor other intoxication are necessary to sleep. On the contrary, we usually sleep to avoid intoxication and to prevent exhaustion. Healthy sleep is not necessarily a poisoning of the nerve elements. There is a periodicity whereby the healthy person, whether he is fatigued or not, has a recurrent appetite for sleep. Sleep has a constructive, anabolic, invigorating effect on the whole body. This is, doubtless, partly due to physical rest, partly to the interruption in the production of toxines arising from muscular contractions, and partly to the absence of stimuli which, during waking hours, excite nervous katabolism.

Some writers have assigned a special importance to a particular region of the brain in connection with the function of sleep, namely, the floor of the third ventricle and the Sylvian aqueduct, pointing out, in support of this theory, the well-known ptosis and divergent strabismus, both of which might be due to a temporary paresis of the ocular nuclei. And they recall the fact that cases of tumour of that region are particularly likely to have early and persistent drowsiness. But some of these cases can be well explained in a different way; sometimes as due to cerebral anæmia. Why? A tumour at the base of the brain may mechanically compress and narrow the arteries which form the circle of Willis. This has been several times demonstrated in cases of tumours of the base and of the third ventricle. Some time ago I had under care a woman, æt. 26, with a cystic growth of the pituitary body and the floor of the third ventricle. Her only symptom was paroxysms of overpowering sleep, which increased, passed into coma and stertor, and she died. She never had any paralysis, nor optic neuritis.

Another help to natural sleep is the absence of violent external stimuli, such as loud sounds or sudden flashes of dazzling light; therefore silence and darkness conduce to sleep. A pleasing monotony of gently reiterated stimuli has a similar soothing effect, such as the sound of waves beating on the shore, or the steady red glow of a fire on a winter's afternoon, or the restful tones of the preacher's voice in church. These things cannot be ascribed to cerebral anæmia, nor to exhaustion, nor to any toxic action. There are different degrees of normal sleep, estimated according to the strength of the stimuli necessary to awaken the sleeper to a consciousness of his surroundings. The lightest is mere drowsiness, in which, although the person is not directing his conscious attention to surrounding objects, he can still be aroused by slight stimuli, such as ordinary conversation or a light touch. The next is sleep with dreams, when the sleeper is unconscious of his surroundings but the psychical centres are still active, though uncontrolled. And under the influence of dreams, while the cortical motor centres are still active, he may perform motor actions, constituting the well-known somnambulism. But this, in health, is rare, because ordinarily the cortical motor cells are dull at the same time as are the sensory cells. Still more pronounced is the sleep which is deep and dreamless. This, under pathological conditions, merges into what we call stupor, and ultimately into coma. The chief distinction between sleep and coma is, that a sleeping person can be aroused, whereas a comatose person cannot.

(a) Delivered at the Polyclinic, Chenies Street, London, February 19th, 1907.

Let us now pass to the consideration of some disorders of sleep. There may be pathological drowsiness, the commonest instance of which, perhaps, is that of the anæmic young woman. This may be partly toxic, from loaded intestines or possibly from decaying teeth, or other sources; but it is mainly vascular. The heart in these cases has but little energy, and the vessels throughout the body are flabby and deficient in tone, and therefore in the erect posture the vessels of the brain are badly filled. If the patient sits down during the day, she feels drowsy; but when she lies down at night the conditions are altered; the brain becomes hyperæmic—still from want of vascular tone—and she accordingly lies awake. Therefore in treating the anæmia we often administer digitalis, combining it with iron, and bromide of potassium. Then the day drowsiness disappears, and the patient is able to sleep at night. Myxœdematous patients are habitually sleepy and stupid, probably from toxæmia; so are many idiots and cretins. And after a severe fit it is not uncommon for an epileptic to fall into a deep sleep. No doubt this sleep is largely due to the toxines produced by the nervous system and by the muscles during the fit. The drowsiness produced by a combination of exhaustion and extreme cold, as in the Arctic regions, is very striking; and it is probably largely the result of deficient circulation, and unless the heart be vigorously stimulated, the sleep is liable to pass on to coma and death. The sleep induced by gazing into a bright fire on a winter's afternoon is something different; it is probably a mild variety of hypnotic sleep. The continuous red glow acts on the optic nerve by a summation of stimuli; it is not merely the temperature, because in the same temperature if the fire be not seen, drowsiness is not so likely to occur. The church drowsiness is also probably explicable on the "summation of stimuli" idea. There are several elements: the soothing monotony of the preacher's voice, the sitting posture of the listener, who, of course, has the additional excuse of cerebral anæmia, and there is the common habit of closing the eyes to avoid visual distractions. This does not apply to "revival" services, where the conditions are very different.

There is also the drowsiness of impending diabetic and uræmic coma, both toxic in origin. Also there is the remarkable "sleeping sickness," which is endemic in certain parts of Africa, and is associated with trypanosomes in the blood, glands, and cerebro-spinal fluid. The drowsiness is no doubt due to some toxine produced by the parasite. In the later stages there is perivascular cerebral infiltration around the cerebral vessels, a variety of chronic meningo-encephalitis.

Then there is narcolepsy, in which the patient suddenly falls asleep in the middle of whatever he may be doing. These cases are usually hysterical.

The hypnotic state is another condition which is analagous, in some respects, to ordinary sleep, but time does not allow us to discuss it here. Suffice it to say that the phenomena of hypnosis may be produced by continuous monotonous stimuli—visual, auditory, or other, aided by suggestion.

Nightmares are horrifying dreams. which produce so much distress that they sometimes wake the person up. They are generally toxic in origin. The commonest cause of nightmare is gastro-intestinal fermentation; we know what the proverbial lobster supper is capable of. They will occur again and again in a child, and it is curious that the character of the nightmare in the child is generally the same each time. In children gastro-intestinal fermentation is a very important factor. Still more frequently we find that the child has got adenoids, which interfere with respiration, and produce a degree of carbonic acid poisoning which acts as a narcotic. Attention to the gastric condition or to the adenoids generally corrects the night-terrors.

Patients with tropical abscess of the liver are particularly liable to horrible dreams, so much so, that they may be afraid to go to sleep; big sturdy soldiers fear to fall off to sleep. Doubtless the cause here also is toxic.

Nightmares are also fairly frequent in those who have aortic regurgitation. Here the cause is probably not toxic, but vascular, due to the irregularity in the blood supply and to pulsation in the cortical capillaries.

Lastly, there is insomnia, or sleeplessness. These cases may be divided into two great classes: (1) Extrinsic; (2) Intrinsic.

Extrinsic insomnia includes those cases in which the sleeplessness is secondary to some outside cause, not necessarily associated either with the brain or with any of its blood vessels. For example, physical pain of any sort will keep a patient awake; so will a cough, or vomiting, frequency of micturition, or diarrhœa, or pruritus. And, of course, in these cases we do not give a hypnotic; we treat the primary symptom, and if we succeed, sleep follows naturally. This group also includes emotional insomnia. This latter is much more often the effect of grief than of joy; and it is more often associated with fear or apprehension for the future than with sorrow for the past. When a pleasurable emotion does cause insomnia, it is generally the anticipation of some happiness, and one in the near future. A man will not lie awake because someone is going to leave him a fortune twenty years hence; but he may spend a sleepless night on the eve of his marriage. The treatment of emotional insomnia, apart from assuaging the patient's sorrow—which is often beyond our sphere—is best accomplished by giving a cerebral sedative, such as a mixture of chloral and bromide. The insomnia of extreme joy we are seldom called upon to treat; but if the patient becomes too excited, we can give cerebral sedatives here also.

But we are often consulted about the other kind of insomnia, the intrinsic. This may be due to vascular, or to toxic, or to nervous faults, or to a combination of all three.

First, as to vascular insomnia. The brain may be hyperæmic; this renders sleep impossible. Hyperæmic insomnia may be of the high-tension type, or of the low-tension type. In high-tension insomnia the patient is often the subject of general arterial sclerosis, or of renal disease, and the hyper-tension is readily demonstrated by the Riva-Rocei sphygmo-manometer The best remedy for such cases, as Broadbent has so long urged, is to give a mercurial aperient, such as blue pill, or calomel, two or three times a week. Of course, we must also lay down general directions as to diet, &c., and regulate the mode of life. Hyperæmic low-tension insomnia occurs in anæmic and neurasthenic patients, as we have already seen. And it is characterised by the fact that when the patient sits upright in a chair she feels drowsy, whereas when she lies in bed at night the brain is over-filled with blood, and consequently she cannot get to sleep. In these cases the best remedy is a cardio-vascular tonic, such as digitalis, and moderate doses of bromide of potassium. Hyperæmic insomnia, whether of the high or low tension form, is generally associated with cold feet; and if the patient's feet can be got warm the cerebral hyperæmia tends to become alleviated. A cup of hot soup or hot milk will cause temporary abdominal hyperæmia, and thus relieve the cerebral congestion.

Insomnia may be one of the distressing features of chronic heart failure. As the patient is dropping off to sleep, he suddenly starts up with a feeling of suffocation, gasping for breath. This form is probably due to deficient circulation in the medulla oblongata. We treat it by cardiac tonics, possibly combined with one of the non-depressant pure hypnotics, or even, in selected cases, with morphia, which we must administer cautiously and combined with atropine.

Next, there is toxic insomnia, and this is one of the commonest varieties met with in practice. Many of these cases are associated with gastric or intestinal fermentation, and especially with dilatation of the stomach. The symptoms are very characteristic. The patient falls asleep, but after an hour or two—the period varying according to the amount of dilatation present, he wakes up, perhaps after a horrible dream; he has profuse sweating, or some gastric uneasiness, and he will have a "sinking feeling" in the abdomen, with a craving for food. If he eats a biscuit, or something of the sort, his stomach contents become diluted for a time and he feels relieved. And this may mislead the patient into thinking that his insomnia is due to exhaustion from want of food, which is far from the fact. During his waking hours the patient is usually depressed, even hypochondriacal, he may be almost melancholic. When we have such a history we should carefully examine the patient's abdomen, and if we find the physical signs of dilated stomach we must treat the patient accordingly: put him on dry diet, free from starchy foods, excluding green vegetables, and attend generally to the intestinal functions. Meanwhile, we should administer gastro-intestinal antiseptics, such as carbolic acid, creasote, or β Napthol, or sulpho-carbolate of soda. To give hypnotics in such a case, without correcting the gastric condition, is worse than useless.

I must now refer to the sleeplessness produced by chronic excess in the use of alcohol. This sleeplessness sometimes culminates in delirium tremens. There is also the insomnia of acute fevers, and that also is toxic. In the insomnia both from fevers and delirium tremens, sleep can often be best induced by putting the patient into a cold pack, or by wet sponging. Tobacco smoking in excess may cause insomnia, partly by a toxic action on the nerve cells, and partly by its influence on the circulation. Strong tea and strong coffee sometimes act in a similar way.

There is also a primary or nervous insomnia, and that is generally due to over-fatigue, especially mental. We see it in busy professional and business men. But in most cases of insomnia there are several factors. There is not only the toxines of exhaustion and of hasty, ill-digested meals, but also a succession of powerful mental stimuli all day long, causing a persistent cerebral hyperæmia.

As to treatment, in cases of primary insomnia, besides correcting anything in the way of gastro-intestinal fermentation or any vascular fault, we should make it a golden rule, I think, to send every case away for a complete holiday. And instances of pure insomnia are proper cases for the employment of pure hypnotics, which have a direct sedative action on the psycho-sensory cortex. The names of these hypnotics are legion. Amongst the most reliable is, perhaps, the old-fashioned paraldehyde. It has a somewhat nauseous taste, but I do not regard that as any drawback, because it will prevent a habit being formed. We do not often hear of people contracting the paraldehyde habit. Other reliable hypnotics are chloral, sulphonal, and veronal. Never give a patient *carte blanche* to take the drug himself; self-drugging with hypnotics is highly dangerous in the layman, and still more so in the medical man, who should never prescribe for himself. He should rather go to his bitterest professional rival.

There are other drugs, even more powerful than those I have mentioned, for example, hyoscine and morphia. They should be resorted to only in cases of obstinate insomnia. In extreme cases of excited mania or melancholia we are justified in giving $\frac{1}{100}$ gr. of hyoscine hypodermically, or we may give morphia $\frac{1}{3}$ gr. with $\frac{1}{100}$ gr. of atropine. It is very important for every mental case to have sleep. Persistent insomnia in cases of insanity is of serious omen, and all modern alienists insist on sleep-charts being kept. Severe insomnia extending over a month in a case of insanity makes the prognosis as to recovery very gloomy indeed.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by J. Bland-Sutton, F.R.C.S., Surgeon to the Middlesex Hospital and Senior Surgeon to the Chelsea Hospital for Women. Subject: "The Value and Fate of Belated Ovaries."*

The Lord Mayor and Corporation of Cardiff, in order to commemorate the recent visit of Their Majesties and H.R.H. The Princess Victoria, intend to present 40,000 specially designed boxes containing milk chocolate to the school children of that city, and have entrusted the execution of this large order to Messrs. J. S. Fry and Sons, Ltd., of Bristol and London, Makers to H.M. the King.

Cambridge Lemonade.—Messrs. Chivers and Sons, Ltd., of Histon, Cambridge, have sent us a sample of their "Cambridge" Lemonade, which is already well known for its refreshing qualities. The convenient form in which it is made up—namely, that of a powder—enables it to be used largely for travelling and pic-nics, as well as for ordinary domestic use. The name of Chivers is a guarantee as to quality.

ORIGINAL PAPERS.

THE GENERAL PRACTITIONER.

III.—HIS PRACTICAL NEEDS.

By J. LIONEL TAYLER, M.R.C.S., L.R.C.P.Lond.

THESE are, I think, four—(1) an efficient literature that is representative of his requirements; (2) leisure to study and to rest with less fear of interruption; (3) incentives for the fostering of research desires; (4) freedom from excessive competition.

(1) *An Efficient Literature.*—This point I have already alluded to in my last paper, and here, I hope, it only needs emphasising. Every worker in any form of activity needs a *representative*, trustworthy literature composed of good reliable text books, *that have a reference value to such worker*, and periodicals, also reliable, dealing with more transient aspects of his employment. These are exactly what the general practitioner lacks because he is still looked upon as a subordinate when he is an independent investigator whose results ought to be related to other medical investigators.

That general medical literature does not attract and is of little use to the ordinary medical man is proved by the little reading on medical subjects which he undertakes. I remember being the guest of a doctor who prided himself on his efficiency after some forty years of practice, and I think in the main his pride was justified, who though he had distinguished himself at college, and had succeeded both financially and by reputation, had not added, as far as I could discover, one single text-book on any branch of medicine to his book-shelves since his student days, nor did he belong to a medical library. This is perhaps exceptional, though I am sure it is less so than is apt to be thought, but it is certain that new books are very seldom added to the medical nucleus that is acquired in student days, and yet if books were really a help, they would unquestionably be bought if only to compete more favourably with other medical men. *This lack of reading is not true to anything like the same extent, of the consultant and the specialist, hence books must serve their ends better than they do the ordinary man's.*

The reason is obvious: A practitioner who sees a patient once, twice, or even several times, but in each case for a special defined reason, and receives his fee for each consultation is on a distinctly different footing from the one who may be called in for any cause, who is frequently on terms of intimacy with the family, and may have all kinds of questions asked him. A book dealing solely with defined diseases satisfies the former, but for the latter it is all but useless.

Such questions as the advisability of marriage for a delicate but not diseased woman or man; advice on girls' or boys' education in relation to their health; on choice of a house, the soil it should rest on, its situation, drainage and sanitation; heredity; diet and food adulterations; exercise and clothing which are all quite legitimate ones, are not adequately treated in any book, so far as I am aware, that is in existence, and are frequently not alluded to. Then there are certain issues that a doctor is quite justly expected to give an authoritative opinion on, such as hydropathy, homeopathy, vivisection, vaccination, hypnotism, faith healing, Christian Science, patent medicines, and he may turn in vain to any one, two, or three works of reference for brief, reliable interesting statements on these subjects. Again bodily temporary or permanent conditions which are not due to disease—and frequently depend upon some error in diet, exercise or vocational habit—such as constipation, flatulence, headache, sleeplessness, but are nevertheless very difficult to treat, are mostly unconsidered. Occasionally one is asked such a question as this, and in the future it will be a frequent one: "Will you please examine me, and tell me if I am healthy?" and to this may be added the still harder point: "and how am I to keep so?" Though insurance books are some help they are really of much less use than would be thought as all the old assumptions of size, weight, height, etc., have broken down, and we simply do not know if a given man is naturally small like a Japanese, heavy like a Welshman, or light like an Irishman, or is unhealthily undersized, heavy, or light. And it is needless to point out that our advice should depend on our diagnosis.

A literature corresponding to the general practitioner's needs is therefore the first essential, and I am convinced that if it existed it would be widely appreciated.

(2) *Leisure to Study.*—The exactions of patients who trouble doctors at all hours of the day and night over quite slight matters must be met. As a student I was once called at three in the morning because a patient wanted a thickened but, he admitted, painless toe-nail cut, and though I have never since had quite so flagrant an example of unreasonableness to contend with, yet, like all other medical men, I have time and again been troubled late in the day or at night with the silliest of trivialities. It is quite useless to attempt to do solid reading under the circumstances, as one is always waiting for the call bell, and so a novel that can be picked up and thrown down again accounts for far too much of the leisure at our disposal. Many men do their best work in their carriage while visiting, reading the weekly medical journal and getting their new ideas largely from such source alone. Others rely on chats with brother practitioners. But in all cases the result is far from satisfactory as most recognise.

The only solution to this difficulty of constant interruption is that which many qualified men have already adopted, namely, of graduating the fee to the lateness of the hour when one's advice is sought, and except during fixed consulting hours, charging one fee before twelve, one and a half between twelve and six, and two fees after this.

Such a rule would apply to all classes alike, it creates no invidious distinctions and it gives the patient the option of sending if the need is great, while it appears to be at the same time an effective deterrent to unreasonable demands. Something of this nature is required to prevent medical men's leisure being wasted.

Of course some arrangement should be made also in reference to obstetrical cases. Beyond a certain number of visits extra fees should be charged for those that the patient is herself responsible for. There is at these times all the difference between the genuinely anxious and the fussy patient and the latter should be made to realise that the trouble that she causes is a costly matter for herself.

If practitioners would combine by some such scheme it would in the end be beneficial not only for the profession at large, but for the general public's own interests, as a higher level of capacity would be possible for medical men to attain to.

(3) *Incentives to Study.*—There are few more curious anomalies than the position of the medical man in regard to medical research. In every other occupation a man has at least the possibility of reward for original investigations. In medicine alone the worker may not profit by the creation of improvements in his calling and yet the person who is not medical may.

It must of course be admitted that the medical position is a peculiar one. Everything must be done to prevent health being considered from the commercial aspect. Advertising is for this reason wholly discreditable. Also to make a profit from the sale of drugs or instruments is equally unsatisfactory. Yet it must be evident to every person who thinks over the matter at all that to deprive a medical man of all remuneration for his labour ***must tend*** to make him less interested in the original aspects of his pursuit and this is an evil of incalculable magnitude.

Further, by removing the true pioneer from his rightful position and not keeping the place vacant, but allowing the little trained chemist and the untrained quack to compete for what is denied to the medical practitioner must, and as a matter of fact does, result in the exploitation of worthless products by adventurers on its worse side and on its better by the production of new drugs that may be of value—but since they cannot be tested therapeutically by chemists, however efficient—are for a long period unsupported by clinical testimony as to their special actions. It is neither to the interest of the patient (who is treated by a medical man who has little incentive to develop his skill and who is imposed upon by untrue advertisements of patent medicines) nor to that of the doctor that this state of things should continue.

To obviate this surely it would be possible to have new remedies tested by specially appointed Government experts, whose own stipends must be unalterable ones, and an award granted to the discoverer for his legitimate labours, which though not large should at least compensate him for his effort. This sum, if it were fixed either in the form of a small unalterable annuity, or by payment of a given amount of money that would be regarded as complete compensation for the discovery, would enable the new product or contrivance to become at once public property, while the discoverer's financial interest in it would at the same time cease. If, further, no other means of patenting any new drug or instrument were legal and the advertising or selling of medical things by unqualified persons was made criminal, a fresh stimulus would be given to the chemist and the medical man in their respective occupations, while the removal from social life of the advertising quack who influences so prejudicially many thousands of people would be an unquestionable gain to humanity.

There is of course nothing new in this proposal. but surely some such recognition of service is desirable. Obviously until labour in this direction is made in some degree remunerative it is impossible for any man who has to earn his living, to spend much effort in a direction where he cannot expect the least return. To thus crush out incentive by giving it no outlet is neither wise national nor individual policy and until such individual incentives are in existence medicine can never take its true position in relation to other scientific studies.

(4) *Excessive Competition.*—Lastly, it is a fact, regret it to what extent we may, that owing to growing competition the various members of the medical profession are becoming increasingly hostile to each other.

Some means of checking this tendency must be found. A minimum fee should, I think, be fixed by the General Medical Council, and doubtless simpler quieter modes of living would accomplish much.

In conclusion, it is along lines such as these that the development of medicine must take place. We must come together on a broader and more friendly basis; we must have more leisure and be treated more considerately by the general public; we must have incentives to study and not see the quack reaping in districts that are rightfully our own; and our literature must recognise and cater for the needs of the general practitioner. Finally by removing the stigma of inferiority from the ordinary medical man by giving him a share in the control of medical institutions and by realising that he has at his command information that can be obtained from no other source it is reasonable to hope that a newer and larger horizon will be revealed to us.

POOR-LAW AND SANITARY ADMINISTRATION IN IRELAND. (a)

By SIR CHARLES A. CAMERON, M.D. F.R.C.P.I., D.P.H.Cantab.

Chief Medical Officer of Health for Dublin.

The Sanitary Acts are administered in Ireland by the following bodies:—1st, the Local Government Board, the supreme public health authority of the country; 2nd, the county boroughs; 3rd, the urban district councils; 4th, the rural district councils.

The Local Government Board has certain powers vested in it by statute, which enables it to supervise the boards of guardians who have charge of the pauper poor, sick or well. The Board must approve of the appointment and dismissal of officers of the guardians; its auditor examines their accounts and makes surcharges if payments of money have been illegally made. If the Board considers that the guardians have neglected their duties, it may supersede them by the appointment of vice-guardians. The Board has much the same power in reference to the boroughs and urban and rural district councils. It must approve of the appointment and dismissal of sanitary officers, and of their salaries and increases of salaries. This practically secures fixity of tenure to the medical officers of health, who are appointed by the sanitary authorities, and in which respect they are in a more secure position than the medical officers of health in England and Scotland.

The Local Government Board contributes to the salaries of the sanitary officers of the local authorities. Dublin received last year more than £2,000 on account of the salaries of the medical superintendent officer of health and the sanitary sub-officers. For some years up to 1902 the Local Government Board paid one half of the salaries of the sanitary officers. In that year an Act of Parliament was passed, which fixed the contribution for that year as the maximum sum that in future could be given. As a result of this Act, the Local Government Board cannot contribute to the increase of salaries or to the salaries of new appointments, if by so doing its contribution would exceed the grant of 1902.

(a) Read at the Conference of the Royal Sanitary Institute, Dublin, June 17th, 1907.

The borough councils are empowered to appoint medical superintendent officers of health, executive sanitary officers, and sanitary sub-officers (another name for inspector of nuisances, or sanitary inspector). They can establish hospitals and work them, or contribute to their maintenance, or do both. Dublin has a smallpox hospital in connection with its Sanitary Department. It has no Corporation general or fever hospital, but it contributes between five and six thousand pounds annually to hospitals under private management. In addition, the Public Health Committee are empowered to pay for the maintenance of fever patients in the fever hospitals, or in the fever wards of the general hospitals. All the powers which Dublin and other county boroughs possess in reference to the appointment of sanitary officers and contributions to hospitals are also enjoyed by the urban and rural district councils.

The Irish Public Health Act of 1875 constituted all the poor-law medical officers *ex-officio* medical officers of health. They were paid by the boards of guardians, but when their districts were situated in towns having sanitary authorities, their salaries were fixed, though not paid, by those authorities. This anomaly ceased on the passage of the Irish Local Government Act, which transferred the payment of the salaries of the medical officers of health from the boards of guardians to the governing bodies of the counties and boroughs, and of the newly-created rural district councils. This Act transferred all the sanitary functions of the boards of guardians to a newly-created set of authorities, termed rural district councils, whose functions are practically the same as the sanitary authorities of the towns. They are practically composed of the boards of guardians, but they have sometimes different chairmen and clerks. They pay the salaries of the *ex-officio* medical officers of health, sanitary sub-officers, &c.

It is now generally conceded that it was a mistake to have converted *nolens volens* the dispensary physicians into medical officers of health. Many of them disliked the new functions, especially as, with very few exceptions, their salaries were very small, often £10 a year. In 1900 a Commission was appointed by the Local Government Board to inquire into the causes of the high death-rate of Dublin. One of the recommendations was that an assistant medical officer of health should be appointed, and the sixteen *ex-officio* medical officers of health relieved of their functions. No authority in Ireland has the power to abolish the *ex-officio* health officers. It has been suggested that in the next proposed Dublin Improvement Act a clause should be inserted to discontinue their services. I doubt very much that Parliament would pass such a clause, for as a rule sections of general Acts are not in any important manner repealed by local Acts. In a general sanitary Act for Ireland, the *ex-officio* health officers might, of course, be dealt with.

One great difficulty in depriving the dispensary physicians of their sanitary functions is the question of compensation. If they were compensated by retiring allowances, then for many years to come the local authorities would have to pay a double set of medical officers of health. Most innovations and improvements are, however, attended with expense; and the abolition of the *ex-officio* health officers, and their replacement by whole-time officers, would (so far, at least, as rural districts are concerned) be worth the expense involved by it. So far as the large towns are concerned, the district medical officers of health perform, on the whole, very good sanitary work. In the rural districts they are handicapped very largely. They have not efficient sanitary sub-officers. The rural district councillors are practically the boards of guardians, who elect and pay them as dispensary physicians or medical officers of the workhouses. The health officers, whenever they make sanitary reports, are not unlikely to give offence to some one or other of the rural district councillors. This is particularly the case as regards the hygiene of the dairy and farmyard. A considerable proportion of the milk supplied to the towns comes from the country. The sanitary sub-officer who is generally also the relieving officer, and who has a salary of only a few pounds a year, can hardly be expected to give much attention to the hygiene of the dairy and cowsheds. He is not qualified by the possession of a certificate of competency to act as a health officer granted by such bodies as The Royal Sanitary Institute. I think it may safely be assumed that in the greater number of the rural districts in Ireland the sanitary laws are practically a dead letter.

It would be most desirable that the Department of Agriculture and Technical Education should take over from the sanitary authorities the supervision of all places in which milk is produced. For the administration of the Disease of Animals Act and the Orders relating to dairies and cowsheds, it has a staff of nearly sixty veterinary surgeons. By an increase of this staff and the appointment of inspectors not veterinary surgeons, but having some knowledge of rural sanitation, the health of dairy stock of the country and the purity of the milk would be far better attended to than they are at present.

Whether or not the *ex-officio* medical officers of health should cease to exist, the county council ought to be empowered to appoint medical officers of health and sanitary sub-officers. If the officers' functions ceased, the sanitary staff of the county would have to be larger than if there were no district medical officers. In England and Scotland, as well as in Ireland, there are district medical officers of health; but that did not prevent the establishment of county officers with powers to act in every district, and to review the proceedings of the local authorities. I would be glad if this Conference would pass a resolution urging the Government to introduce a Bill for the appointment of County Medical Officers of Health.

DR. F. H. SCOTT, who wishes to continue his researches into the metabolic processes of nerve-cells has had the accrued income of the Gunning Fund placed at his disposal for the purpose.

TWENTY-THREE YEARS OF GYNÆCOLOGICAL PROGRESS. (a)

By W. D. SPANTON, F.R.C.S.Eng.,

Consulting Surgeon, North Staffordshire Infirmary, &c.

To attempt a general survey of the work accomplished by our society during the past twenty-three years would be quite impossible in the time at my disposal. It becomes a duty, nevertheless, to recall some of the more important features of it, which afford a convincing proof of its usefulness and of the value of the results it has accomplished.

To begin with, I have to revert to the early days of recognised gynæcology in this country, when strong convictions and abundant moral courage were vitally necessary. These attributes fortunately some of our pioneers possessed, and enabled them to lay the foundation for the scientific study of British gynæcology as a distinct and important branch of special surgery.

The Foundation Meeting was held on December 27th, 1884; and I find, on looking through the first list of officers of the Society, only one of the vice-presidents is still with us, the veteran Dr. C. H. Routh, though of the original Council we have still one-half remaining among our Fellows. The objects were expressed to be "to promote and encourage the science of gynæcology," and Dr. R. Barnes then said he was "sure its existence would be abundantly justified by honest and useful work." This prophecy has, we know, now been abundantly fulfilled.

The first specimen shown by Dr. Wallace was a typical one of degeneration in multiple uterine myomata, where hysterectomy had been performed; and it seems to strike the key-note of one of the most important tunes which our society has had to sing—that of early surgical interference in all such cases. But the most advanced surgeons on the same occasion concurred in the speaker's remarks that "to extirpate a tumour simply because it was a tumour, which gave little or no trouble, and which in all probability would finally disappear, implied taking a responsibility on the part of the surgeon which he ought to decline." This view, I am glad to say, has been reiterated in an emphatic manner at one of our recent meetings. No one subject has been so fully dealt with as that of uterine tumours; and valuable investigations have been recorded, throwing light on their pathology and treatment; but I do not find anyone bold enough to enter upon their causation. That seems as much a mystery as ever, and might form a good topic for the new Royal Society of Medicine.

We find in the very early days (1884) some discussions on the Listerian mode of treatment in laparotomies and kindred operations; and a divergence of views was even then beginning to manifest itself in vigorous language. At that period numerous cases were brought forward of ovarian and parovarian tumours of all kinds, and uterine appendages removed for a multiplicity of conditions. It was about this time an outcry arose against what some persons deemed the too frequent and indiscriminate operations of this class; and although, in looking back, it is evident enough that the evils were greatly exaggerated, a more conservative policy was the direct result, so that good came of it.

One condition, however often referred to—that of diseases of the Fallopian tubes—was in its early stage of evolution, for we find frequent reference to the difficulties encountered by the best operators of that day, notably Lawson Tait and Dr. Bantock; the same difficulties as are encountered still, but with more accurately defined knowledge how to deal with them, derived from the experience of operators in the past. The treatment of pelvic abscess by abdominal section has been frequently dealt with, being first brought prominently forward by Dr. Richard T. Smith and Mayo Robson. Associated with this, a discussion on "Puerperal Septicæmia" elicited some emphatic remarks from Lawson Tait and Robert Barnes, that "whenever pus formed and collected in the abdomen and pelvis, the indication was strong to make an incision into the abdomen and give it exit."

The subject of Porro's operation (spoken of as amputation of the uterus), brought forward by Dr. Godson, drew attention to its advantages, under specified conditions, over that of Cæsarian Section.

That all-important disease, cancer of the uterus, has received a large share of attention from this society, and the consensus of opinion is that, like cancer elsewhere, if it can be thoroughly removed early enough a cure will follow; and although, in advanced cases, no remedy has yet been found which will effect a cure, much may be done by removal of the diseased tissues in various ways, to prolong and make more comfortable the patient's remaining life. Early hysterectomy, all agree, offers the best chance for the patient. The treatment of uterine tumours by electrolysis, as advocated by Apostoli, found favour with a minority only, and was strongly condemned by others—chiefly those who had never tried it. That it has its uses, few will deny; though it seems to have fallen almost into disuse now. Another important aspect of myoma in connection with pregnancy has been before us, which illustrates forcibly the close association of obstetrics and gynæcology. As in most things, there are two sides to the question, and it is well to hear both before arriving at any definite conclusion as to the right course to adopt in every such case.

We find scattered among the records many subjects of general interest, which, having a special bearing on gynæcology, have been discussed from that standpoint. Among them, the dangers of the use of morphia, conveying a very suggestive note of warning.

The treatment of uterine prolapse has been fully dealt with, and the ventral methods compared with the vaginal freely discussed. When the causes are so diverse, the treatment must necessarily be very varied too; and it becomes quite impossible to do more than indicate what may be considered the best mode of treatment for well-defined conditions—no universal rule is possible.

Of displacements of the uterus, with reference to mechanical support, much has been said; but it would seem that opinions as to the best method remain as varied as ever. I fear that, until men and women are made of some more rigid material than living flesh and blood, there always must be a difference of opinion regarding the treatment of conditions which cannot, in their very nature, be fixed quantities. As we proceed, we find such matters as cholecystotomy and nephrolithotomy described. These were, to a large extent, novelties then; the beginning of great things for those branches of abdominal surgery which have now arrived at the stage of having specialists of their own. The very wide subject of dysmenorrhœa has, at various times, been freely discussed, and, each time it comes up, some new light is able to be thrown upon it. Social matters of interest have been dealt with from time to time—notably the Midwives Bill introduced in 1890, since in a modified form passed into law, conducing without doubt to the safety of parturient women who were formerly in the hands of ignorant persons.

During our last short session, many interesting subjects have been discussed, most of them having a practical bearing on everyday gynæcological work rather than of an academic character. Among them may be mentioned membranous dysmenorrhœa, a subject of importance to the general practitioner, and about which much has yet to be learned.

We are indebted to Professor Jacobs, of Brussels, for bringing before us the subject of the radical treatment of prolapsus uteri, more especially by means of an extensive operation he described. This led to a valuable discussion, and the views of many Fellows who took part in it were freely expressed, and will be found recorded in the valuable volume (the last, unfortunately) of our *Transactions*.

The important subject of the surgical treatment of inflammatory diseases of the uterine appendages was

---

(a) A Valedictory Presidential Address read before the British Gynæcological Society, July 11th, 1907.

once more brought forward by Dr. A. E. Giles—another reminder of vexed controversies which a few years ago would have provoked acrimonious debate. It is one of those matters which time and experience have helped to make clear, and enabled certain rules for guidance in treatment to be laid down, which must prove helpful to less experienced practitioners. Reference was very suitably made to the exhaustive work in this department carried out by Dr. Cullingworth; and there is no doubt that he, and Lawson Tait, were those chiefly instrumental in showing the necessity for surgical action in cases of this class. Now that they are able to be better differentiated, and the conditions more accurately defined, what was once decried as an empirical, is now fully accepted as a scientific mode of treatment. For this result we have wholly to thank the gynæcologists.

Another interesting paper brought before us, rather surgical than gynæcological, by Mr. Stanmore Bishop, was that of movable kidney. The influence of this condition on a woman's life was entered into, and led to some varied views. Some would look on it rather as a symptom or an effect than a cause; and a fear was expressed lest surgery should take the place of other measures. For my own part I am firmly convinced that a mobile kidney is often a sole cause of some of the most troublesome ailments in women, especially on the left side, where it sometimes simulates very closely the symptoms of gastric ulcer—on the right side, its frequent association with appendicitis is also easy of explanation. But to ascribe, as has been done by some authors, such remote troubles as insanity to a mobile kidney, seems to me beyond the ken of modern gynæcologists, at any rate.

At our last meeting, we had the advantage of having brought before us, by one so eminently qualified to speak as Mr. Mayo Robson, the question of the treatment of general peritonitis. This is, indeed, an important one for all surgeons, and needs all the light that can be brought to bear upon it by skilled minds. On this occasion, as usual, diverse views were expressed; but one and all agreed that the modern treatment of this condition, by which every effort is made to assist nature rather than to thwart her efforts, has been a great advance. To open the abdomen early; whenever possible, to remove the cause, and then trust to natural processes to complete the work is what we now aim at. Those who attempt too much, equally with others who stand by and do too little, usually come short of success. It was especially fitting in a practical society like ours, that this subject should have recrudesced, and led to a discussion which is certain to result in good.

It would be a grave dereliction of duty on my part if I were to omit some reference to the indefatigable and valuable labours of some of our Fellows, who have, by their energy and their influence, overcome the difficulties which were inherent to the union of our society with the new Royal Society of Medicine. To Dr. Macnaughton-Jones, Mr. B. Jessett, Dr. Slimon, and Dr. Beckett-Overy especially, our warmest thanks are due; and I feel sure that, in years to come, when the Obstetrical and Gynæcological Section of the Royal Society of Medicine is thoroughly established, everyone will look back with the utmost satisfaction, and with grateful feelings, to those who have been instrumental in its accomplishment.

One achievement on which the Society has good reason to congratulate itself, is the series of valuable *Transactions* which have been published, and will remain as a monument of practical gynæcological literature. It is not too much to say that the success which has attended the society is, in no small measure, to be attributed to the full and admirable manner in which its work has been recorded, and correlated with that of other countries

Sir Thomas Browne wrote that "as the work of Creation was above Nature, so is its adversary annihilation, without which the world hath not its end, but its mutation." So of our society. Its birth is now to us "a sleep and a forgetting," and "the soul that rises with us, our life's star," will find its apotheosis in the higher life which lies before us in our new sphere.

Now, to our old Society, we have to bid "Farewell."

"EXTINCTUS AMABITUR IDEM."

CLINICAL RECORDS.

CASE OF FIBRO-MYOMA OF THE VAGINA.

By J. H. SWANTON, M.D.,, M.Ch., M.R.C.P.Lond.
Physician for Diseases of Women, Kensington General Hospital, etc.

The patient, C.G., from whom this growth was removed, was æt. 40, a widow, whose occupation was that of cook.

She came to hospital complaining of pain in her back and lower part of abdomen, frequency of micturition, and painful defœcation. The only previous illness was described as inflammation of the bowels. Menstruation commenced at 14 years of age, regularly appeared every 28 days, and lasted seven days with scanty loss. She had pain occasionally before each period. The patient had been pregnant five times, her eldest child was æt. 18, and she had four miscarriages, the last having occurred five years ago, after a pregnancy of three months. She nursed her child for nine months.

Her present illness began three months ago with pain in her back, caused by standing. There was a red vaginal discharge which came on every fourteen days. There was dysuria without frequency of micturition. She had been getting thinner recently. The patient was thin and had an anxious expression with agitated manner. The superficial reflexes were increased. The abdominal muscles were rigid. There was a red vaginal discharge with a faint odour. The urethra was drawn upwards; the uterus was enlarged, and its consistence increased; the fundus was retrodeviated and not freely movable. Both external and internal piles were found.

In September, 1906, she returned, complaining of backache. The uterus was now movable, A nodule was found in the vaginal vault at the junction of the anterior and posterior left quadrants. The mucosa could be removed freely over it. The uterus was anteverted and a suitable pessary inserted. In October, 1906, the tumour was found to have become enlarged and the surrounding tissues were less sharply defined. In February, 1907, the nodule had not altered much, but the surrounding infiltration was greater. On conjoined manipulation the uterus was found to be painful, In March, 1907, the patient was admitted, when the uterus was curetted and the vaginal tumour removed at the same time, owing to its increased growth. An incision was made into the mucosa and the tumour found to be attached to the muscular wall by a pedicle, which was cut through after ligaturing and the growth then removed. The wound was sutured with iodised catgut and healed without complication.

The tumour measured three-quarters of an inch in its longest axis and one-third in the shortest. The surface was irregularly lobulated, of pearly white colour, with subcapsular areas of hæmorrhage. On section a capsule was found externally enclosing a mottled central portion made of irregularly-arranged whitish tissue in strands surrounding areas of grey tissue; also a looser tissue of the same kind on one side immediately under the capsule. After serial staining of one set of sections with hæmatoxylin and eosin and another with Van Giesson's fluid microscopical examination showed that the fibres of the capsule were loosely arranged with polymorphonuclear cells scattered between, and in other portions some extravasations of blood were seen.

The central portion consisted of white fibrous tissue arranged in whorls and unstriped muscular tissue irregularly interspersed. The arterioles in the central portion showed hypertrophy of the middle coat, as observed by Mr. Stanmore Bishop, and described in a communication read before the British Gynæcological Society and recorded in the XVII. Volume of its Transactions.

The patient was discharged in seven days after the operation and convalesced in a satisfactory manner.

In connection with the etiology of these growths Cornil and Ranvier have associated them with syphilis, but in this particular instance sufficient evidence was not forthcoming.

Fibro-myomata of the vagina are rare. Machenhauer has collected reports of seventy cases, and stated they were found in women between forty and fifty years of age. They varied in size from a cherry to that of a fœtal head, and are found in the upper part of the anterior wall, being chiefly sessile. The surface may occasionally ulcerate.

CASE OF CYST OF THE CLITORIS.

The patient from whom this cyst was removed was a dancer, æt. 20, who complained of a painful swelling on her vulva early in May, 1907. Her menstruation, which began at fourteen, appeared regularly every twenty-eight days, lasted four, and was scanty. There was a thick yellow inter-menstrual discharge. She had been married for two years, and was pregnant a year ago, but aborted after two months. Since then her menstruation has been irregular, being more frequent and of longer duration.

The onset of this growth was dated from an injury received while dancing, what she described as the "cobbler" dance, three months previously.

The swelling gradually increased in size, but after manipulation three days previously it became rapidly larger, more painful, and accompanied with dysuria. The patient gave a history of alcoholism. The tumour became smaller during menstruation.

On examination the clitoris was found to be the seat of a fluctuating tender, dusky, tumour about three-quarters of an inch across. The bifurcation of the anterior extremity of the left labium minus was widely separated owing to the size of the cyst. As the symptoms were urgent the tumour was tapped, giving exit to a quantity of coagulated blood mixed with a thick oleaginous fluid followed by a thin greyish fluid with a faint odour. The patient experienced such relief that further treatment was refused. In ten days afterwards, however, she was admitted into hospital owing to a return of pain and swelling. The growth had extended under the anterior commissure and vestibule to the right side. The tumour was removed by making a triangular incision reaching from the suspensory ligament to a point about an inch outside each labium minus, and another across the vestibule. The cyst was dissected out without rupture. Hæmorrhage was free, but easily controlled by deep mattress sutures of catgut, the skin being united by continuous catgut sutures.

The growth consisted of a thick walled oval cyst about 1½ inches in length and ¾ inch across. There was a small opening anteriorily from which purulent fluid exuded. The wall was three-sixteenths of an inch in its thickest portion, and diminished down to a membrane anteriorly. The contents consisted of pus and fatty debris, but no cholesterin was found. The anterior two-thirds of the inner surface of the cyst wall was hæmorrhagic. The inner surface generally was rugose with traces of septa, more marked in the posterior third. On microscopical examination the walls were made up of laminated layers of connective tissue with numerous vascular spaces; more internally the tissue was necrotic with numerous polymorphonuclear leucocytes and lymphocytes. There was no trace of a distinct lining membrane. The differential diagnosis must be made between a dermoid cyst, fatty tumour, sebaceous cyst and chronic abscess. The attachment of the cyst to the skin, the known date of onset, and its position were against a dermoid cyst. The absence of lobulation and the firm consistence would distinguish it from a lipoma. The diagnosis between a sebaceous cyst and a chronic abscess was not so easily disposed of, but the history and structure of wall were in favour of its being a sebaceous cyst in which suppuration had recently taken place.

The patient was discharged convalescent on the sixth day after the operation.

OPERATING THEATRES.

GREAT NORTHERN HOSPITAL.

Double Osteotomy of the Femur for Knock-Knee.—Mr. Arthur Edmunds operated on a female child, æt. 5, who was suffering from an extreme degree of knock-knee. The child was a thin, ill-nourished little girl, who had obviously been the subject of severe rickets, but, with the exception of the deformity of the femora, the mal-nutrition presented no other deformities. When the child lay down with the internal condyles of the femora in apposition, the internal malleoli were separated by about seven inches. The deformity in knock-knee, Mr. Edmunds pointed out, may be mainly due to a curvature at the lower end of the femur, or it may be due also to a curve at the upper end of the tibia. It was very rare to find the curve in the tibia alone. By flexing the leg at the knee-joint, it was always possible to make out the share played by each bone in the production of the deformity. If the femur is alone affected the internal condyles and the malleoli can be made to touch simultaneously when the knees are flexed. For example, if a child be placed on a table so that the knees hang over the edge, the deformity completely disappears. In early stages of knock-knee, while the bones are yet soft, a simple splint will usually suffice to completely cure the deformity; but when the bones have become more firmly ossified—that is to say, when a child is æt. about 5—this mode of treatment is not sufficient, and osteotomy has to be performed. Osteotomy, however, although it seems at first sight such a trivial operation, is very frequently a severe strain on the constitution of these weakly children, and after prolonged immobilisation in plaster of Paris, the legs are often found so weak and wasted that it is a very long time before the child is able to walk. In the present case the child on admission was so poorly nourished that it was not thought advisable to perform an osteotomy, until she had been sent away to the country for several months. Her condition on re-admission to the hospital was very much improved and operation was accordingly undertaken. Many types of osteotomy have, Mr. Edmunds said, been introduced, but the linear osteotomy on the lines laid down by McEwen was perhaps the best. An incision about three-quarters of an inch long, above and in front of the adductor tubercle, was made down to the bone and the osteotome introduced, twisted to 90°, separating during its rotation the periosteum from the bone. The bone was then divided, its various portions being dealt with systematically, and any remaining spicules fractured; the leg could then be brought into good position. The wound was closed with a few sutures. The opposite leg was then treated in exactly a similar manner, and both legs dressed and bandaged to half box-splints. It was felt desirable to avoid the prolonged plaster of Paris treatment, and as soon as the wounds were healed systematic daily massage would be commenced. Massage in fracture not only, Mr. Edmunds said, prevents the adhesions forming between muscles and articular surfaces of bones, but also maintains the nutrition of the limb and enormously accelerates bony union.

In the present case, at the end of three weeks, although both femora had been completely divided, no movement could be detected between the fragments and the child was able to stand alone. The splints were removed, and the child was encouraged to move the legs in bed. After another fortnight's rest the girl was allowed to get up and run about. She was kept in the ward for some time longer in order to make quite certain that the union was stable, and was then discharged six weeks after the operation. Mr. Edmunds pointed out that by treating cases in this way, that is to say by early massage, firm union is obtained much more readily, and the period of convalescence materially shortened.

TRANSACTIONS OF SOCIETIES.

THE BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD THURSDAY, JULY 11TH, 1907.

Mr. W. D. SPANTON, F.R.C.S., President, in the Chair.

SPECIMENS.

DR. J. H. SWANTON showed a fibro-myoma of the vagina; an account of this case will be found on page 89 of the present issue.

Dr. MACNAUGHTON-JONES said such tumours occurred comparatively infrequently. Up to the last time that he had occasion to collect statistics of fibromyomata of the vagina there had been about 260 cases. Dr. John Phillips brought forward the records of 29 cases which he had collected, up to the beginning of the year 1905. One of the most important points of interest about such tumours was as to whether they degenerated and became malignant. There were certain cases on record in which those tumours had become sarcomatous. Sometimes they assumed a myxomatous character, but as a rule they did not produce any remarkable symptoms. The age of onset did not correspond with that of malignant disease generally, for they occurred between 30 and 50. They were seen far more frequently in the anterior wall than in the posterior wall. They frequently had a pedicle and sometimes were found as multiple sessile tumours. He believed they seldom became malignant.

PROFESSOR TAYLOR said he had met with four instances of fibro-myoma of the vagina, all of them having occurred in the anterior wall, and all were sessile. In one case the growth was recurrent. He operated on four different occasions, removing the growth from the same situation, and finally cauterising the base. In that case he expected to find the tumour was sarcomatous, but he had the satisfaction of knowing that the last operation had maintained its efficacy longer than any before. Three years had elapsed since the operation, and he found that the histological characters of the tumour were those of simple myoma.

Dr. MACAN said it would be an interesting question in the pathology of these growths if we could distinguish between abnormal growths of fibroid tissue in the abdominal wall in the ovaries, uterus, and vagina.

The PRESIDENT said he did not remember having had a case of the kind. It seemed that everything now centred around the possibility of malignancy supervening in what had always been regarded as simple growths, and this was the line of investigation for the future.

Dr. SWANTON, in reply, said none of the speakers had touched on the association of syphilis with such tumours. Cornil and Ranvier found several cases of the kind were associated with a syphilitic history.

He next showed a specimen of Glandular Cystic Adeno-carcinoma of Ovaries and Vermiform Appendix an account of which will appear in our next issue.

The PRESIDENT said he regarded this as being an instance of the type to which he had already referred, namely, of suggesting innocency at first and then subsequently a rather rapid development of malignancy. He had been especially struck by the extreme malignancy of these growths.

Dr. GILES said one point which particularly concerned him was the question of diagnosis, which in this case, was that of fibroids. Carcinoma of the ovary was a condition which was not often diagnosed directly, especially where there was no free fluid present in the abdomen. The presence of free fluid and cachexia in the patient would suggest that it had a malignant element. He had met with four cases of carcinoma of the ovary not associated with any fluid in the abdomen and all were associated with uterine fibroids. In some, the fibroids were comparatively small, but in all operation was undertaken for fibroids, the presence of an ovarian tumour not having been suspected in any one of them. That was perhaps easily understood, inasmuch as those tumours had a comparatively solid consistence, and when there were multiple fibroids the irregularities might equally indicate them with ovarian growths in addition. Where fluid was present, he thought the prognosis was in most cases bad. In other cases carcinoma of the ovary might be attended with a good prognosis. One of the four cases to which he had just alluded had since died of recurrence, but the other three patients were alive and well at the present time, the periods which had so far elapsed since the operation varying from two to three years. Therefore he considered that if the growth was not attended with free fluid, which meant that the growth had not perforated its capsule, the prognosis might be fairly good.

Dr. MACNAUGHTON-JONES said he exhibited the largest carcinoma of one ovary he had ever seen. There was a fibro-adenoma of the other ovary. At the time the patient was reduced in weight to about 5st. She lived six months afterwards and then died of recurrence of the carcinoma in the bowel. Some years afterwards he showed to the Society carcinoma of both ovaries with large carcinomatous masses and fibro-myomata of the uterus co-existing. He quite agreed that the seriousness of those cases depended upon the escape of carcinomatous fluid. In one of the cases to which he had referred the tumour was solid, and the others were of a cystic character, and the prognosis largely depended upon perforation with escape of some of the fluid into the peritoneal cavity. But on the other hand, he considered that, as a rule, cases of malignant growth of the ovary would be found to terminate fatally.

Dr. MACAN pointed out how often malignant diseases of the ovary were bilateral. All would agree that the occurrence of ascites with any tumour of the ovary pointed to an unfavourable prognosis, and this was especially so when tumours were found on both sides. He had recently the opportunity of looking at the very valuable work of Professor Winter's on diagnosis, and that authority laid great stress on the fact that in malignant disease of the ovaries one was apt to find that both ovaries were affected more or less, though not necessarily to an equal degree.

Dr. E. A. NEATBY said he wished to know whether carcinoma of the ovary occurred frequently as a primary condition. Mr. Bland-Sutton, Dr. Cuthbert Lockyer, and others had recently pointed out how often they occurred secondarily to either some intestinal or some mammary growth. A few months ago he removed a large ovarian carcinoma, and at the same time he found a nodule in the small intestine which he took to be carcinoma, but which he did not consider advisable to remove. He warned the friends that she would probably have to come back for operation later on, and when she returned some months later she was then so weak that she died before operation could be undertaken. Post-mortem it was found that the growth in the small intestine was columnar-celled carcinoma, very much resembling in character that which was found in the ovary. He would be glad to hear what the experience of members had been in that regard, as to the frequency of such growths of a secondary nature in the ovary.

Dr. SWANTON, in reply, said there was no evidence at that time of operation of perforation of the capsule of the cyst, although it might possibly have occurred at a previous date. He diagnosed fibroid growth because the uterus was increased in size and, moreover, was adherent to the mass behind in the pouch of Douglas. His own experience had also been that bilateral malignant disease of the ovarian tissue was more frequent than unilateral disease of that region. He thought his case must have been one of primary carcinoma, because there was no evidence in the abdomen of any other growths beyond that which was shown under the microscope, which occurred in the vermiform appendix. It seemed to him the cystic condition had existed some time previously, and only recently malignant degeneration had come on. The statistics of the frequency of primary ovarian carcinoma showed it to be rather more common than secondary carcinoma.

A MYOMA OF UNUSUAL INTEREST.

Dr. H. **Macnaughton-Jones** showed a large myoma removed from a patient, æt. 32, unmarried. There had been, comparatively speaking, few symptoms, the only one of importance being menorrhagia and consequent anæmia. On exposure of this tumour he had found it quite encapsuled with peritoneum. This was subsequently explained by Dr. Cuthbert Lockyer's report on it, as he says: "The growth arose in the right side of the body and cervix, and has burrowed beneath the peritoneum of the floor of the pelvis." Another peculiar histological feature was the presence of a sacular cavity or long cul-de-sac, which he thought was the dilated and thinned out uterine body which had degenerated. On subsequent examination this was found to have collapsed and the uterus was seen to be incorporated with the tumour. Dr. Lockyer regards this cul-de-sac as a dilated lymphatic, and has found this deceptive resemblance to a uterine cavity on previous occasions. Both ovaries were removed, having degenerated, and lutein hæmatomatous cysts being present.

Professor J. W. **Taylor** asked whether Dr. Macnaughton-Jones did not think the cavity could be accounted for by the separation of the layers of the peritoneum. Sometimes when a fibroid grew into the broad ligament on one side of the uterus he had found the peritoneum separated and the growth more or less encapsulated, a triangular space was formed either above or below the tumour.

The **President** thought that whenever we met with a case of myoma of the uterus there was always some interesting point which was worth discussing. The interesting points about the present one appeared to be the complete capsule, and the small cavity which was formed. He was inclined to agree with the suggestion that it was a simple matter for some inflammatory material to have separated the two layers of peritoneum and formed a sort of false sac.

Dr. **Macnaughton-Jones**, in reply, said Dr. Cuthbert Lockyer's opinion was that the cavity was a lymphatic sac.

Dr. **Swanton** read notes of a case of Cyst of Clitoris, which will be found on page 90.

The **President** thought such cases must be exceedingly rare, although cysts occurred in various parts of the vagina, and often proved troublesome. From the description it did not seem to present any indications of malignant outgrowth.

Professor **Taylor** thought the situation of the growth was unusual. As far as one could judge, it seemed to be of a sebaceous character. He had met with a sebaceous cyst very much like that, but not occurring in the clitoris; it was in the labium minus of one side. He regarded the specimen as a suppurating sebaceous cyst.

Dr. **Macan** said that cysts of that character in the clitoris were very rare. He could not remember any cases recorded in literature. Professor Taylor's explanation of the present case seemed to be the most likely, that it probably arose from sebaceous glands. But in the absence of microscopical details he did not see how the matter could be decided.

Dr. **Swanton**, in reply, said his difficulty in giving further information about the cyst arose from the fact that such a length of time elapsed between the first appearance of the growth and the time at which the operation was performed. The evidence indicated that it was a sebaceous cyst which had suppurated.

THE PRESIDENT'S VALEDICTORY ADDRESS.

The **President** announced that he had received letters of apology for absence from several of the Fellows.

Professor J. W. **Taylor** said he had much pleasure in proposing that the best thanks of the Society be accorded to the President for his Valedictory Address. He hoped it would not be regarded by the President as one of the least of the many honours he had possessed that it was under his presidency that the Society made a great step forward by the junction with its sister organisation, the Obstetrical Society of London in the new Royal Society of Medicine.

Dr. H. **Macnaughton-Jones** had much pleasure in seconding the vote of thanks proposed by Professor Taylor, and would refer to the Minutes of the Council of the Society as to its origin. Those Minutes were interesting from an historical aspect and recorded that: "Several members of the profession specially practising gynæcology considering the time was ripe for the formation of a Gynæcological Society, seeing the question had been omitted for some years past, agreed to meet together to consult and see if such was feasible, and, accordingly, on Monday, December 22nd, 1884, the following met at 27 George Street, Hanover Square: Dr. Meadows, Dr. Robert Barnes, Dr. Aveling, Dr. Bantock, Dr. Heywood Smith, Dr. Fancourt Barnes, Dr. Edis. Dr. Meadows took the chair, and after some remarks from him, Dr. Heywood Smith read letters which had been received from several who had been in favour of the project, and it was agreed to call a meeting of medical men for Saturday, December 27th, 1884, at the rooms of the Medical Society by means of the following circular, of which he would only read one Clause: "Owing to the extraordinary neglect of gynæcology in the general hospitals and their conspicuously inadequate provision of beds for the treatment of diseases of women, special hospitals entirely devoted to gynæcological work have been established." There had been 201 meetings of the Society, and 213 or 215 meetings of its council. He wished to mention the names of Dr. Meadows, Dr. Bantock, Dr. Fancourt Barnes, Lawson Tait, Dr. Charles Routh, Dr. Macan, Greig Smith, Dr. Edis, and Dr. Bedford Fenwick, because they were the names of the men who in the early years of the society had borne the burden and heat of the day. But he also thought that anyone who spoke at the last meeting of the society should acknowledge fully the debt which the society owed to its provincial Fellows. (Hear, hear.) Wherever one might look, in England, abroad, or in the Colonies, we found provincial Fellows of this Society among the most distinguished. One of them was present that evening, a gentleman who not only had been President of the Society, but for whom the Fellows entertained great respect, Professor Taylor. The Society was not the first medical body to admit women to their meetings. Perhaps he might be allowed to say it was the only blot on the escutcheon of the Society that they did not welcome women before they did. But he felt certain that the action of the Obstetrical Society of London in the matter was taken largely because they knew the Gynæcological Society intended doing it. They were glad and proud that it was a provincial Fellow of Mr. Spanton's standing and eminence who occupied the chair of the Society at its dissolution.

The resolution was then carried by acclamation.

The **President** expressed his deep obligation to Professor Taylor and Dr. Macnaughton-Jones for the words in which they had respectively proposed and seconded the resolution, and to the meeting for passing it.

Dr. **Heywood Smith** said they would not be able to separate happily unless they passed a special vote of thanks to one who had really borne the brunt of the whole difficult negotiations which led to the amalgamation, namely, Dr. Macnaughton-Jones. They were justified in congratulating themselves on the work which the Society had done.

Dr. **Richard Smith** seconded the vote of thanks to Dr. Macnaughton-Jones and those who had been associated with him in the work with great pleasure, for the negotiations had an harmonious ending. He was present on one occasion when Mr. Erichsen said at University College that he thought they had arrived at finality in surgery. But what would he have thought now? They all rejoiced in the progress which had been made, and trusted that the future might be even more productive than the past.

The resolution was then put and carried by acclamation.

Dr. Macnaughton-Jones, in acknowledging the vote of thanks, said that it would be more suitable that he should thank the Society for all the help which had been given to him rather than that it should thank him for what he had done to bring about amalgamation. The first President of the Section would be the present President of the Obstetrical Society of London for the time being, Dr. Herbert Spencer. The Fellows of the Obstetrical Society who would form part of the Council would be Dr. Henry Russell Andrews, Dr. Henry Briggs, Dr. Champneys, Dr. Cullingworth, Dr. Dakin, Dr. G. Eastes, Dr. Fairbairn, Dr. Gow, Dr. Handfield Jones, Dr. Herman, Dr. Kerr, Dr. Lewers, Dr. Cuthbert Lockyer, Dr. John Phillips, Dr. Amand Routh, Mrs. Mary Scharlieb, Dr. Herbert Williamson, Dr. Thomas Wilson, with Dr. Robert Boxall as one of the Secretaries. As was understood, each Fellow of the present Society would be a Member of the new Section of the Royal Society of Medicine. It would be seen that the laws which were drawn up were founded upon the general principle of the new Royal Society of Medicine, which was a thoroughly democratic principle.

Dr. Macan proposed: "That we desire to record our appreciation of the courtesy and cordiality with which the Obstetrical Society of London has united with our Society in their arrangements for amalgamation." He believed it was clear that the members of the Obstetrical Society had treated the Fellows of the Gynæcological Society with the greatest consideration and an appreciation of that attitude should be put upon record.

Dr. Slimon seconded the resolution, and it was carried unanimously.

FRANCE.

Paris, July 21st, 1907.

Extra-Uterine Pregnancy.

The diagnosis of extra-uterine pregnancy constitutes, in certain cases, one of the most difficult problems of obstetrics. It must be made in the first and second periods of the pregnancy.

During the first months, there exists no certain sign that the woman is pregnant, and the presence of ectopic pregnancy can only be suspected from the history of the case, symptoms of probability, bloody discharge, pain, the presence of a tumour lying against the uterus which has not the volume of the age of the gestation and whose cavity is empty. However, nothing can be affirmed, and the pregnancy might be confounded with: A uterine fibroma, hydro-salpingitis, hemato-salpynx, retro-uterine hæmatocele, retro-version of the gravid uterus, abortion.

A fibroma is intimately connected with the uterus of which it is a direct prolongation; it is not sensitive to pressure and palpation. Metrorrhagia is abundant and painless; its development is slow; the cervix is not spongy to the touch. In certain cases, the diagnosis is impossible.

In the different forms of salpingitis, the distinction is equally difficult. In the research of the causes, it may be possible to establish the existence of an anterior genital infection: Gonorrhœa, abortion, tuberculosis, syphilis. The pain is seated in one of the iliac fossæ or in both, extends down the thighs and is relieved by rest. The menses are painful with more or less violent colic; they are irregular and frequently hæmorrhagic.

To the touch, the os appears healthy or is the seat of metritis; the body of the uterus is increased and painful, while the posterior and lateral culs-de-sac are filled by the inflamed organs. On the other hand, women suffering from salpingitis present a special facies; they are pale, emaciated, dyspeptic, and neurasthenic.

In the majority of the cases of hæmatocele, the rupture of an extra-uterine pregnancy is the cause; sudden and intense pain in the abdomen, signs of internal hæmorrhage, tendency to syncope; later, the presence of a more or less voluminous tumour, at first fluctuating, afterwards becoming hard and resisting; the cervix is pushed forward and applied behind the symphisis of the pubis.

In retro-version of the gravid uterus, the os presents the normal sponginess, and bi-manual examination proves that the uterus alone is increased in volume, and if the tumour can be reduced there is no doubt possible as to the existence of a normal pregnancy.

During the last months of ectopic pregnancy, the diagnosis becomes singularly easy. The fœtal cyst becomes more evident and can be easily felt on one of the sides of the median line. By auscultation the movements of the fœtus can be perceived as well as the bruit de souffle and the heart beats. Where the fœtus is dead the difficulties of diagnosis are increased. In such case, diverse questions put to patient may throw light on the nature of the tumour; if there existed symptoms of abortive labour, if membranes were expelled, if the breasts had increased in volume, if the volume of the abdomen had diminished, &c. In practising several successive examinations, the attendant will be able to satisfy himself if the tumour is in way of regression, if there exists osseous crepitation, a sign of great importance when established.

The prognosis is almost always fatal for the child and very grave for the mother.

As to treatment, extra-uterine pregnancy should be considered, said Woerth, as a malignant tumour, and requires extirpation as soon as it is diagnosed, while other authors advise expectancy where the pregnancy has reached beyond five months, and that the fœtus is alive. But the patient should be constantly watched so that an operation could be made at the first signal.

Where the fœtus is dead, and if there are no bad symptoms, the operation may be deferred until the hæmorrhage is less abundant by reason of the decrease of the cysto-placental circulation.

Acute Rheumatism and the Thyroid Gland.

There seems to be a correlation between the thyroid gland and the articular inflammation of rheumatism. M. Vincent reports several cases of acute articular rheumatism, where the thyroid gland was increased in volume and very painful to pressure. Sometimes, on the other hand, the gland is hardly perceptible to inspection or palpation, but in those cases the rheumatic fever runs an ordinary course. In other patients, after a temporary reaction of the thyroid gland, it diminishes considerably in volume, while the articular symptoms persist. Improvement is slow, and the malady leaves the patient in a state of anæmia and prostration.

GERMANY.

Berlin, July 21st, 1907.

At the Medizinische Gesellschaft, Hr. Westenhoeffer showed lymphatic tumours of the stomach and intestines from a patient who had died from leucæmia. The tumours were in part ulcerated, from which fatal hæmorrhage had taken place.

Hr. Ernst Mai reported on Escarine lately recommended by G. Klemperer for hæmorrhage from the stomach. Ten cases had been treated by it in the Moabit Hospital. In all of them the bleeding stopped at once, so that the day after no blood was found even in the stools, although milk and eggs had been given on the first day, whilst the former custom in the department had been not to give patients with bleeding from gastric ulcer any food by the mouth for the first three days.

Out of the ten cases the bleeding returned in one only, and the case proved fatal. The autopsy showed carcinoma. Escarine was a mixture of the finest aluminium powder in glycerine. It was prepared for sale in tablet form, in tubes with six tablets each, of 2.5 grm. each, of which four to five tablets were given stirred in water. This dose was given two days consecutively. It was cheaper than the continued use of bismuth powder. He had given the remedy to rabbits and dogs in which an abrasion of the mucous membrane had been caused by a wound, and on the animals being killed the mixture was found to be well spread over the wounded surface.

Hr. Ewald, although he had given large doses of bismuth for long periods, had never seen any symptoms of poisoning from it. He had also tried escarine and had seen good results from it; it did not always do good however; thus in one case he had given it for three consecutive days, but the bleeding steadily returned in spite of it, and only ceased after gastro-enterostomy.

Hr. Niemann read a paper on

The Practical Results of the Feeding of Infants with Buttermilk.

He first of all emphasized the fact that only perfectly fresh buttermilk made in large establishments came into consideration. As an addition, 15 grm. of wheatmeal and 60 grm. of sugar were added to each litre of buttermilk. These were shredded in under continuous stirring, the mixture was boiled for a short time, and then kept cool; 120 infants were fed with it, 102 with a good result. Very little children, and those above æt. 8 months, were not suited for this form of feeding.

Twenty-six healthy children, who had not thriven well on a diet partly of cow's milk, did excellently on this. Of 71 children with intestinal catarrh, 63 bore the buttermilk diet well; but it must not be given too early, not until the third day, when the acute symptoms had subsided. The combination acted well especially in children who were much run down after intestinal catarrh or were otherwise atrophic. If a greater proportion of fat was desired, cream could be added. By means of a large series of curves the influence of buttermilk on the increase of weight was shown, and, in conclusion, he observed that any early repugnance was soon overcome, and no vomiting took place, but the bowels required regular watching; the stools were mostly alkaline, but acid in about 28 per cent. Not unfrequently, on commencing with the buttermilk diet, a slight increase of temperature was observed; if this remained or got higher the diet had to be changed.

Hr. Cassel believed that with healthy children the buttermilk diet could be given from the first; it was also well adapted for mixed feeding; its proper domain, however, was in intestinal catarrh after the acute stage had subsided, and in atrophic children. The difficulty to the general introduction of buttermilk feeding lay in its very precise technique, and the great watchfulness required. Soxhlet's feeding sugar might be given in place of sugar. It was best to begin with small doses and increase them very gradually. The stool reaction was of no importance, but if vomiting occurred, if the stools were frequent and squirty, if the abdomen was distended and tender, the diet must be changed at once. If at first there was repugnance to the food it might be overcome by giving it by the spoon and cold. There was sometimes a difficulty in weaning from buttermilk; this was assisted by an addition of cream or 3 to 5 per cent. of ramogen, then passing on to half-milk or two-thirds milk. It was not correct that rickets came on more frequently with buttermilk feeding than otherwise. Its chief advantage lay in its poorness in fats and in its purity.

Hr. Jaffa remarked that buttermilk feeding had its distinct indications; it was suited for all children who could not bear fats; on the other hand its richness in sugar prevented its being well borne by all children.

AUSTRIA.

Vienna, July 21st, 1907.

Simulated Monoplegia.

Erben showed a case of monoplegia, which gave rise to a long controversy on the physiology and anatomy of the limbs. Erben wished to prove to the members by his mode of examination that paralysis was not real, but Tandler disputed the case.

Tandler said, if a man were laid prone, and his knee bent up to a right angle on the leg, and then allowed to fall, it would descend in the normal direction by the action of the quadriceps, viz., rectus, vastus, externus, and internus, and crureus. If the lower part of the leg be bent past this right angle towards the body when in the same position, the leg would fall towards the body in paralysis, but he doubted if the first experiment was due to the contraction of the quadriceps. If a perfectly healthy man be tried in this way over the right angle the leg will violently assume the stretched position. For part of the first movement he admitted that the tonus of the quadriceps governed the movement in the healthy subject, but in the dead body there was none.

At this point Reiner presented a case of bilateral quadriceps paralysis, the result of polio-myelitis seven years ago. Tandler's phenomena were clearly demonstrated. The peculiarity of both muscles being similarly affected was a source of surprise, as the cells in both of the anterior cornua must have suffered. It was also proved by this case that the quadriceps could be dispensed with in standing erect, which the patient could do admirably; but when he attempted to walk the defect was instantly observed, by the tension of the plantar muscles and the stamping character in motion. In coming down stairs he substituted the action of the quadriceps by swinging round the descending foot with the point of the foot outstretched to reach the lower step, while the opposite side swung round to perform the next step, which resembled talipes equinus in extension.

With this patient, Erben performed his method, which Tandler objected to, all proving how paralysis can be simulated; after which Tandler admitted that Erben had some foundation for his proof, but had changed his position since demonstrating his own case.

Thrombosis Arteria Vertebralis.

Algyogyi presented a case with symptoms he would place before the members for their judgment: Right eyelids and pupil narrower than left, reaction prompt, right bulbus more sunken, movement to both sides free, no double vision, slight nystagmus in lateral vision, fundus in both normal, sensory and motor function of trigeminus normal, slight insufficiency of the muscles of the lips on right side, pronounced in laughing; uvula tense, with smell, taste, and hearing intact.

There was decided hoarseness in consequence of paralysis of the right vocal cord; but no real cause could be discovered. Motility in limbs free, but slight adynamia of the right arm and hand was present.

Sensibility on right side normal, particularly in the region of the trigeminus, but the left in this part was markedly dull; Faradic pain, and temperature quite lost. This defect extended below the fourth cervical vertebra, and extended round the trunk. There was no ataxy or Romberg symptom present. The thoracic organs, with the exception of the second aortic tone, perfectly normal, and the same might be said of the abdomen.

Pulse 85, right patellar reflex too high, plantar reflex absent on left side but normal on right. Abdominal reflex increased on right; radius right increased. Reflex of palate and pharynx gone, while that of conjunctiva and cornea was present.

Weight before illness, 82, kilos; now 78. Urine gave 5.2 per cent. of sugar; other constituents normal, but with specific diet the sugar fell to 0.1 per cent.

From these symptoms the medulla oblongata would be accused as the centre, and probably the right half, which might be acute or apoplectic bulbar paralysis. From the symptoms it would seem that the vascular system is at fault somewhere, and as hæmorrhage into the oblongata is a rare occurrence and usually associated with violent symptoms, loss of conscience and a speedy termination, which were absent in this case, we must fall back on the more progressive lesion of a partial thrombus in the vertebral artery.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Centenary of the Edinburgh Royal Asylum.—The hundredth anniversary of the foundation of Morningside Asylum was commemorated on July 12th by a garden-party held in the Institution, which was attended by some fifteen hundred guests. Happily the weather was propitious, and the function passed off successfully. The whole of the grounds and most of the buildings were available for the purposes of the function, and the quaint sixteenth century architecture of Old Craig House, once the residence of John Hill Burton, the Scottish historian, was viewed with special interest. A mass of the buildings and grounds enabled the guests to find their way unaided to points of special interest, including Criaglockhart Hill, which is 500 ft. above sea level and commands a magnificent view of the town and surrounding country. The awakening of Edinburgh to the need for some means of caring for the insane is associated with the death of the Poet Fergusson in 1774. Fergusson was one from whom Burns drew some of his inspiration; he became insane and died amid squalid surroundings in the old city Bedlam. The sad circumstances attending his death aroused the compassion of some of the more public-minded citizens, foremost among whom was Dr. Andrew Duncan, Senior, one of the leading philanthropists of the day, and one to whom Edinburgh owes more charities than the Royal Asylum. He circulated a pamphlet proposing the establishment of a lunatic asylum, being at the time President of the College of Physicians, but, though some support was secured for the project, immediate succour was not attained. Later, a Parliamentary grant of £2,000, drawn from the estates forfeited by Jacobites in the '15 and '45 ("one good result of rebellion," the History of the Asylum has it) was obtained, and a Royal Charter was granted in April, 1807. The asylum was actually opened for patients on July 19th, 1813, and the structure thus initiated served until 1837. Accommodation was offered only to those who had means, and in that year the claims of the indigent insane were at last recognized as so strong that the institution was extended to meet the case of those who could pay nothing, or little, for admission. In 1877, the whole institution was reorganised. Dr. Clouston, who succeeded Dr. Skae in 1873, took a leading part in this. He visited the chief asylums in America and on the Continent, and the reconstruction was carried out along the lines suggested by this visit. West House was almost entirely rebuilt and the East House was temporarily enlarged pending the completion of the buildings on the Craig House estate, purchased about that time. Old Craig House was retained in its original form as an old mansion house, while the new buildings were scattered about the grounds in the form of villa residences. During the past 90 years, £370,000 has been spent on land and buildings; of this amount £284,100 has been paid off. The income from private patients has risen from £12,000 to £38,000, and the staff now numbers 269 persons. Since its reconstruction the asylum has taken a creditable place among the public institutions of Edinburgh, and has maintained a reputation as being in the van of medical science.

Royal Visit to Edinburgh.—Their Royal Highnesses the Prince and Princess of Wales paid a visit to Edinburgh last week in order to fulfil several public engagements. On July 11th, they made a brief tour of inspection of the Royal Infirmary, where they were received by the Lord Provost, Colonel Warburton (Superintendent), Mr. Caw (Treasurer), and Miss Gill (Superintendent of Nurses). In the outer hall the Board of Managers, and in the inner hall members of the medical and surgical staffs, including Drs. Greenfield, Bramwell, Bruce, Russell, Grelland, Graham Brown, Fleming, Ritchie, and Rainy, and Messrs. Annandale, Chiene, Macgillwray, George Mackay, Cathcart, Paterson, and Guy were presented to the Prince and Princess. The Royal Party then proceeded to the Diamond Jubilee Pavilion, and visited Ward 35, in which gynæcological cases are treated. Dr. Barbour, the physician-in-charge, and Drs. Fordyce and Haullan, assistant physicians, were present and accompanied their Royal Highnesses round the ward. The Prince of Wales, in conversation with Colonel Warburton, asked many questions regarding the expenditure of the institution, and treatment and feeding of the patients, and indicated that for economical management the Infirmary compared favourably with other institutions of which he had personal knowledge. After going through the wards and operating theatre the Royal party visited the lower corridor in order to see the dedicatory memorial tablet, with the appearance of which they expressed gratification. The visit was a comparatively short one, lasting only some thirty minutes, and at its close the Prince and Princess expressed themselves as highly satisfied with the brightness and airiness of the Infirmary, and much impressed by its extent.

Compliment to Sir A. R. Simpson.—On July 15th, a complimentary ceremony took place in the Edinburgh Royal Maternity Hospital, the Committee who had undertaken the duty of making some recognition of Sir A. R. Simpson's long and distinguished career, meeting the Board of Directors there, and asking their acceptance of a gift of money towards the endowment of a bed. Mr. Nicholson, on handing over the cheque, said that the Committee thought the object they had in view of showing their appreciation of Sir Alex. Simpson, could best be attained by endowing a bed in the institution in which he had always taken so lively an interest, and which bore the name of his uncle, Sir James Young Simpson. The Chairman of the Board thanked the Committee and said he considered it a high honour to the hospital to have such a permanent memorial of Sir Alexander Simpson.

LETTERS TO THE EDITOR.

ENGLAND AND GERMANY—A CONTRAST.

To the Editor of The Medical Press and Circular.

Sir,—Your correspondent "M. O. H." in his letter of July 10th, asks whether English local government, judged by results, is a failure? No one who knows enough about German methods can fail to answer this query in the affirmative. Germany, under a scientifically-guided bureaucracy, is making immense strides. Her people, as a whole, stand on a higher plane of civilisation than ours. They are better educated, and have more self-respect. Ragged vagabonds, unemployables are as difficult to discover as the class of 'Arry and 'Arriett. I have never met anyone who has ever encountered a drunken woman in Germany. The people are profoundly discontented with their Government in the region of higher politics, but understand and recognise the necessity of obedience and co-operation in matters affecting social progress. They are, for example, all vaccinated and re-vaccinated, so that small-pox is virtually extinct, and they are ready to obey any evidently beneficial police order, however trivial, down to the cropping of their children's hair. School children for years have all been systematically inspected medically, and sorted and dealt with in accordance with physical and mental standards. The three years' military service leaves a highly beneficial mark on the bulk of the young manhood, and almost completely prevents the manufacture of the hooligan class. The condition of the homes of the working men and poor everywhere, including the big towns where the housing problem is acute, is, on the whole, very superior to that common in England. This fact was dwelt upon in the remarkable report of the Birmingham brass-workers after their full enquiry in Berlin. In England sanitary laws are almost everywhere imperfectly administered for the reason which "M. O. H." points out, namely, that the mass of citizens are too selfish and indifferent to take a due share in local Government. Local governing bodies are everywhere too largely made up of ignorant or selfish men, and these, through lack of local public opinion, neglect the laws it is their duty to administer. An essay would be needed to expose fully the contrast between the two peoples in every social phase. Germany has in the Fatherland almost ten millions more people than the total population of European blood in the whole British Empire, and is increasing at the rate of nearly a million a year. Unless the teaching of history is worthless, the expansion of this mighty race should convey a warning and a lesson to patriotic Englishmen and the statesmen by whom they are guided and led.

I am, Sir, yours truly,
A Student of Sociology.

July 19th, 1907.

QUACK DENTISTS AND A ROYAL COMMISSION.

To the Editor of The Medical Press and Circular.

Sir,—I notice that the quack dentists affect great indignation at the suggestion that a Royal Commission on Quackery should include them in its scope. The dental speciality is a legally recognised branch of the medical profession, and under the same administration —the Medical Council—and could not be left out of the enquiry. One would have thought that unqualified men, if they had any justification for their position, would have welcomed investigation, and even personal cross-examination as to their methods by leading counsel. They will be liable to be subpœnaed and compelled to give evidence. If, as there need be no doubt, a Commission should be in due course appointed, we shall then, at least, have a full public exposure of what is now dark in this direction.

I am, sir, yours truly,
A Hospital Dentist.

July 18th, 1907.

OBITUARY.

DR. ALFRED LLOYD OWEN, M.D., OF SOUTHSEA.

We greatly regret to record the death of Dr. Lloyd Owen, of Southsea, on the 4th inst., which sad and unexpected event has deprived a large circle of friends of a greatly valued adviser, and his professional brethren also of a wise, experienced, and much-esteemed colleague.

Lloyd Owen was born at Portsmouth in August, 1845, and he was the third son of Mr. Jeremiah Owen, who then held a high and important position in the Royal Dockyard. He was educated at Christ's Hospital and on leaving the school he went to Trinity College, Dublin, and there passed through a distinguished career as a student. In 1866, he obtained the degrees of B.A. and M.B.Dublin, and also the diploma of M.R.C.S.Eng. After a short absence he returned to Trinity College, and took the degree of M.D. He was appointed house surgeon to the Royal Free Hospital, London, in 1867. In 1869 he married the daughter of the late Dr. William Gibney, surgeon of the 15th Hussars, and soon after entered into partnership with the late Mr. Husband, of York, the senior surgeon of York County Hospital, and treasurer of the British Medical Association. He did not remain, however, long in Yorkshire, for in 1870 he commenced practice in Southsea—formerly only a suburb of Portsmouth, but at this period it had become a fashionable resort which was largely due to the skill and enterprise of Dr. Lloyd Owen's uncle, Mr. Thomas Owen, who for several years was Mayor of Portsmouth, and occupied a leading position in the neighbourhood.

By his natural ability, unflagging industry, and extreme courtesy, Dr. Lloyd Owen soon obtained a high professional reputation and an extensive practice. He held the appointment of surgeon on the staff of the Royal Portsmouth Hospital for 35 years with great distinction, and on his retirement in 1906 he received the warm and hearty thanks of the Committee of Management, and was elected consulting surgeon to the hospital. During this long period his services were greatly appreciated by the suffering poor, and he did much to help forward the progress and development of the Institution. For many years he also held the important post of Admiralty surgeon at Portsmouth.

As a surgeon, Lloyd Owen's career was very successful. He was an excellent practitioner, painstaking in the discharge of every duty, and enjoyed to a remarkable extent public confidence and esteem. Of his qualities of head and heart no one could speak too highly. The writer of these few lines had for years many opportunities of estimating his character. Personally, he was a true and faithful friend, with a transparent integrity and courtesy visible in every action. A striking example of his kindness of heart was exhibited during his last illness by his anxiety to secure a grant of money from the surgical aid fund of the hospital to help a poor girl, whose limb he had removed, in obtaining an artificial limb.

In his home life he was a devoted husband and father, and now the deep sympathy of all who knew him is with his widow and her family in their sudden and irreparable loss and sorrow.

Dr. Lloyd leaves behind him five sons and one daughter. Two of his sons are officers in the Royal Navy, and two are serving in the Army.

The funeral took place at Southsea on the 8th inst. with universal expressions of regret, and around his grave there was a great gathering of old friends and colleagues, who were present to pay a last tribute to one whose memory will ever be associated with the warmest and kindest recollections.

J. W. C.

DR. JAMES DUNSMURE, OF EDINBURGH.

Much regret, as well as surprise, was felt in Edinburgh on hearing the sad news of the unexpected death of Dr. Dunsmure, which took place on July 15th. Some weeks ago he underwent an operation, and apparently rallied from it, but on the 15th, he had a relapse and died very suddenly from heart failure. Dr. Dunsmure came of a medical stock, his father, like himself, having been one of the best-known practitioners in Edinburgh. He was educated at Edinburgh, and studied in Berlin and Vienna, and on his return home succeeded to his father's practice and to many of the appointments his father held. Then he became medical adviser to the Governors of Trinity Hospital, the Alexander Mortification, John Watson's Institution, the Trades Maiden Hospital, and the N.B. Railway Company. Like his father, he was a President of the Royal College of Surgeons of Edinburgh, and took a keen interest in the Quarter Centenary celebration of a few years back. During his term as President, he had the honorary degree of LL.D. conferred on him by the University of Glasgow. He was a keen sportsman, and delighted in shooting, fishing, and golf; along with three friends he made a point of playing a weekly foursome at Musselburgh Dr. Dunsmure was of a somewhat retiring disposition, but was a kind-hearted genial man, and had few equals either as companion or host. He was a widower, and is survived by his only daughter.

J. S. F.

FRANCIS HYDE FORSHALL, M.R.C.P.Ed., M.R.C.S., L.R.C.P.

We regret to announce the death of Dr. Francis Hyde Forshall, which occurred on July 6th, at Highgate, in his seventy-fourth year. Dr. Forshall was the youngest son of the late Rev. Josiah Forshall, F.R.S., formerly Secretary and Keeper of the Manuscripts at the British Museum. He was educated at Tonbridge School, Edinburgh University, and St. Bartholomew's Hospital. When he was qualified as L.R.C.P., he joined the Medical Department of the Army, in which he remained about seven years, seeing service in India and Canada. After leaving the Army he studied in Paris for a time, and then went to Highgate, where he entered into partnership with the late Dr. Harrison. He held several public appointments during his active life, including the

Police Surgency to the Y Division and the medical officership of the Highgate and Muswell Hill Dispensary. Dr. Forshall retired from practice sixteen years ago, and was then presented with some very beautiful silver of the George II. period, valued at £300, and an illuminated address.

REVIEWS OF BOOKS.

PHYSICAL DIAGNOSIS. (*a*)

THIS volume forms an excellent handbook of physical diagnosis. In spite of the many admirable works in existence dealing with that subject, the author may be congratulated on having added to the number another having various praiseworthy and peculiar features. The accuracy of the matter is maintained at a high and consistent level. The work being confined to some 450 pages, the author has wisely contented himself with dealing fully with more important sections, such as the application of systematic methods of physical examination to the thorax, heart and pericardium, and the abdomen. Many points are in this way necessarily either omitted or dealt with briefly. For instance, we find no mention of exophthalmos, nor of exophthalmic "goitre" beyond a casual reference to the visible pulsation often present in that condition. On the whole, however, Dr. Anders may be congratulated on the brilliant way in which he has performed his task, although the American methods of spelling will jar the susceptibilities of educated English readers. There are many excellent diagrams and other illustrations, but most noteworthy of all is the fine series of plates illustrating the Röntgen-ray diagnosis of various thoracic and abdominal conditions. One illustrating the intestinal contents is specially interesting.

DISEASES OF THE EYE. (*b*)

THE author, in his book, has set himself the task of writing a concise description of the commoner eye diseases, designed solely to meet the needs of the physician engaged in general practice, rather than a complete treatise on eye disease. Remembering that a "little knowledge is dangerous," Dr. Theobald does not encourage his readers to trust to such methods as ophthalmology, retinoscopy, or perimetry as an aid to diagnosis, unless they have opportunities of considerable practice in perfecting themselves in these arts. Such methods of examination as oblique illumination and the perimeter are well described and in the case of the latter sufficiently fully for ordinary purposes. We like the way Dr. Theobald lays down his treatment of the various diseases. Instead of enumerating several remedies which *might* cure, and leaving it to the inexperienced reader to take his choice, he lays down one or two courses which his experience has taught him to be usually efficient. The appendix contains a useful list of prescriptions with a short note as to the indications of each, which will be welcome to many; and although there is nothing original in the book, nothing, in fact, that cannot be found in existing authorities, the author has been, on the whole, successful in being simple and precise in his descriptions of prevalent diseases and their treatment.

NEW BOOKS AND NEW EDITIONS.

THE following have been received for review since the publication of our last monthly list:—

SIDNEY APPLETON (London).
The Principles and Practice of Dermatology. By Wm. A. Pusey, A.M., M.D. Illustrated. Pp. 1,021. Price 25s. net.

JOHN BALE, SONS AND DANIELSSOHN, LTD. (London).
The Haslemere Museum Gazette. Conducted by Jonathan Hutchinson, F.R.C.S., LL.D., F.R.S., assisted by E. W. Swanton. Vol. I., 1906 and 1907. Pp. 622. Price 7s. net.

BAILLIERE, TINDALL AND COX (London).

Weekly Summary of Medical Literature, English and Foreign.

Specially compiled for The Medical Press and Circular.

RECENT SURGICAL LITERATURE.

The Rôle of the Various Elements in the Development and Regeneration of Bone.—Sir Wm. MacEwen (*Brit. Med. Journ.*, June 22nd, 1907) undertook this inquiry by direct experiment. The subject is dealt with under two heads: (*a*) To test the potentiality of periosteum as a factor in the reproduction of bone. It was found that (1) when a complete cylinder, constituting a portion of the shaft of a long bone, was removed while the periosteum was preserved intact, that ten weeks later an osseous defect was found constituting a gap in the continuity of the shaft; (2) periosteum freed from osseous plaques when removed and transplanted was not followed by reproduction of bone, but by the absorption of periosteum; (3) silver rings were placed on bone deprived of periosteum, with the result that in each case the rings became covered by bone. (*b*) The regeneration of bone, from proliferation of osseous tissue. (4) Direct experiment, showing that a long bone deprived of its periosteum continues to grow; (5) so also do flat bones of the skull; (6) bone may be made to grow in the midst of lacerated muscles by the mechanical distribution of osteoblast; (7) shavings of nude bone placed between muscles in a gap in the continuity of the shaft showed in seven weeks, not only that they grow, but that they also proliferate to a very marked extent; (8) there is direct evidence to show that transplanted living bone actually grows and proliferates, instead of forming, like blood-clot, a passive framework for the granulation tissue to penetrate, which framework will then become absorbed; (9) to test the osteogenetic power of bone cells constituting the shaft of a long bone, they were grown inside of a glass tube. S.

The Use of Massage and Movement in the Treatment of Fractures.—Cathcart (*Scottish Med. and Surg. Journ.*, July, 1907), from personal experience, has come to the following conclusions on this subject (1) Absolute immobility of the broken ends of bone is not essential to bony union. (2) Extravasated blood in joints, and among muscles and synovial sheaths, leads to adhesions in its neighbourhood, apart from the bruising and laceration of soft parts which accompanies fracture. (3) Massage, in the form of stroking and gentle kneading, and with it occasional movements are beneficial in the treatment of fractures, as they aid the actual union of bones, help in the absorption of effused blood and serum, restrain if not prevent the formation of adhesions among the soft parts, and maintain the nutrition of the muscles. They therefore simultaneously hasten union and prepare the limb to return to functional use almost as soon as the bones are united. (4) Splints, extensions, &c., are more to prevent mal-union, than non-union. (5) The manipulation necessary for the massage and movement treatment of fractures can be successfully carried out by anyone who will take the trouble to understand the object of manipulation and is sufficiently gentle to handle the part without causing pain. In recent fractures, massage diminishes swelling, allays muscular spasm, and soothes pain. When there is much pain and spasm of the muscles passing over the broken bone a small hypodermic of morphia or hot fomentations are of advantage. The limb is well dried and dusted with some fine powder to facilitate rubbing. Gentle stroking of the limb should be begun on the proximal side of the injury, the amount of pressure to be used must be guided by the sensations of the patient, as the patient must not be caused any pain. Even when a general anæsthetic is required, preliminary massage should be employed to reduce effusion before splints are applied. As regards movements, active movements will help to prevent stiffness, and passive movements will help to maintain nutrition. Gentle passive movements should be used first. Both forms of movement require to be used with care so as to avoid displacement of the broken ends of bones; and pain and serious discomfort to the patient must always be avoided. There is one form of active movement to which the author calls especial attention, that is in the reduction of displacement due to muscular contraction. Apparently voluntary efforts insure relaxation of the displacing muscles together with contraction of those that are helpful in reducing the deformity. Discussing splints, the author considers that they are useful (1) to prevent deformity, and while pain on movement lasts; (2) to give support to the seat of fracture and adjacent parts. He considers that the long splint for treatment of fracture of the shaft of the femur will seldom now be needed, since we no longer wish to fix the hip and knee-joint, except in restless children and delirious adults, and since we can quite well prevent rotation outwards of the lower fragment by sand-bags. There are cases in which continuous extension by weights or an elastic cord are indispensable to obtain the best possible apposition of broken ends of bones. But the extension should not be continued too long—not after ten days to three weeks. The author discusses the treatment in reference to various common fractures, including fracture of the olecranon and patella. S.

Notes of an Experience of Stovain as a Spinal Analgesia in 100 Cases.—Pringle (*Brit. Med. Journ.* July 6th, 1907), who has been employing this method of producing anæsthesia for operations in Glasgow, used Bier's preparation of stovain with epirenane, as put up by Billon, of Paris, in 98 of his cases; two patients got Chaput's preparation. The injection is made with the patient sitting up and the shoulders arched. There is seldom any pain in connection with the injection, which is best made in the first lumbar space. It is essential to get a free run of cerebro-spinal fluid when the trocar is withdrawn. After the stovain (from .04 to .06 cg.) is injected, the pressure of the cerebro-spinal fluid is, in the majority of patients, sufficiently great to force the syringe plunger back into the barrel, and this is allowed to occur several times to ensure a good mixture of the solution with the fluid. The effects are produced in from five to fifteen minutes. Usually muscular paralysis of the lower limbs is complete before sensation is abolished. Analgesia has, on an average, reached the level of the tenth dorsal nerve. In one case it was complete up to the clavicle on both sides without any respiratory difficulty being induced. The highest incision under stovain was for umbilical hernia. Very few patients manifested any discomfort during the period they were under the influence of the drug. There was a little retching or vomiting in the case of a few, and four patients had syncopal attacks; but in no case was there any anxiety about the condition. The ages of the patients varied from 13 years to 80 years. In two cases unilateral analgesia only occurred. The 100 operation cases included amputations of the thigh (2), hernias (31), appendicitis (12), wiring fractures (6), suprapubic prostatectomy (3), inguinal colostomy (2), pyonephrosis (1), &c. Among these 100 patients there were 22 cases of failure to induce analgesia sufficient to allow the operation to be completed. The after-effects of stovain have not been troublesome at all. Headaches have been complained of by some patients, and one or two have vomited a little after operation; but in neither case were these symptoms as severe as is often seen after ether and chloroform. A good number of patients complain greatly of pain in the wound for the first hour or two after the operation,

more so than after a general anæsthetic. In conclusion, the author has no doubt that in stovain we have a very excellent anæsthetic for the region comprising the lower limbs, and the lower part of the abdomen, even though it may be a little uncertain in its action.
S.

Symptomatic Varicocele in Malignant Tumours of the Kidney.—P. Hochenbegg (*Zeitschr. fur Klin. Med. Bd.* 62) says symptomatic varicocele can be distinguished from idiopathic varicocele in the following way : Let the patient lie down, at once the idiopathic varicocele disappears, only the relaxed condition of the scrotum remaining, but in the case of the symptomatic or secondary varicocele, this will become perhaps more tense on the patient assuming the horizontal position, or will in any case only slightly diminish in size. Symptomatic varicocele usually appears at an advanced age, and comes on more or less suddenly ; it is produced under various conditions ; the tumour may invade the renal vein and occlude the opening of the spermatic vein. This condition is, of course, only possible on the left side. The growth may infect the lymphatic glands, in which the spermatic and renal veins become imbedded and compressed. The spermatic vein may become occluded by the weight of the tumour ; it is in such cases that the varicocele becomes tenser when the patient lies down. The kidney may be dragged downwards by the weight of the tumour and the veins become kinked ; this occurs more frequently on the left side than on the right. The presence of a varicocele, due to either of the two last-mentioned causes, does not alter the prognosis, but if its presence is due to either of the two first-mentioned causes, then the case is inoperable. If posture and manipulation of the tumour is without effect on the variocele the prognosis is not good. Of sixteen cases of malignant tumour of the kidney observed by the writer, symptomatic varicocele was present in six of these patients. G.

An Improved Preparation for Intra-Muscular Injections of Mercury.—F. J. Lambkin (*Lancet*, July 6th, 1907) calls attention to a new preparation of the insoluble salts of mercury he has used with great success lately, the vehicle used for the suspension of the mercury being pure palmatin, which has the great advantage of being a soluble constituent of the organism, in place of the insoluble substances formerly used. The success which has followed on combining this preparation with camphorated creasote, as an analgesic, begins a new era in the treatment of syphilis by intra-muscular injections of insoluble salts of mercury, for, in the first instance, one great objection to the treatment, *i.e.*, the introduction of insoluble foreign bodies into the circulation—is done away with, and, in the second place, pain has been practically abolished, even in the case of calomel, so that this drug can now be used fearlessly in every case in which the surgeon thinks its use is indicated. G.

The Treatment of Lupus.—Dr. Drew (*Lancet*, July 13th, 1907) describes a method of treating lupus. The lupus patch to be treated is frozen with ethyl chloride till it is snow white ; over this frozen surface crude hydrochloric acid is rubbed in thoroughly, and with some degree of force. This thorough surface cauterisation should be carried out about once a week as long as it is necessary, that is, until only deeper nodules remain (lupus fibroma). The remaining nodules are cured by puncture cauterisation. The advantages of this method are : (1) It is simple, cheap, rapidly effective, and gives good cosmetic results ; (2) It can be carried out at home without hospital treatment, and this is specially important for patients with limited means ; (3) Complicated apparatus is not necessary, therefore the method can be applied by any practitioner.; (4) The method can be applied in all forms of lupus and in all situations, with the exception, perhaps, of the eye. Favourable results are obtained by repeated cauterisation, especially of lupus of the nasal cavity ; (5) As a preliminary for later Finsen treatment one gains time and gets favourable results. G.

Punctured Fractures of the Base of the Skull.—R. L. Knaggs, in a paper (*Lancet*, June 1st, 1907) on this subject, draws attention to the frequency with which such injuries as punctured fractures of the base of the skull are overlooked ; two or three days often pass during which the patient goes about as usual, then brain symptoms appear sometimes quite suddenly, and the patient may die in the course of a few hours. It is well to remember the paths by which a foreign body may reach the base of the skull. The most usual one is through the orbit ; the orbit is not necessarily entered from the front, but may be crossed from below upwards, or reached from inside the zygomatic arch, and the position of the skin wound may be such that it will arouse no suspicion that the brain has been injured. Another path is through the mouth, pharynx or nose ; this latter is very rare. Another not uncommon route passes through inside the zygomatic arch, the external wound is usually in the cheek and the lower jaw may be damaged. Lastly, the convex portion of the posterior segment of the skull may be wounded directly. It is also well to remember that often such wounds are regarded by patients as trivial, and they may only seek advice with the onset of brain symptoms. In cases where the foreign body inflicting the wound is long, slender, and brittle, a portion may readily be left behind, and retained in the skull. Lastly, it is well to remember that even if the immediate danger of death from cerebral hæmorrhage or injury is escaped there is a tendency to later septic complications, which may be deferred for several days. At the base of the skull the majority of the venous sinuses are situated ; it is unfortunate that the converging walls of the outer part of the orbits tend to direct a weapon towards this dangerous area. G.

Obstruction of the Central Retinal Vein.—Verhoeff, Boston (*Ophthalmic Review*, December, 1906) in dealing with the pathological findings of six cases of his own and twelve reported cases diagnosed ophthalmoscopically as thrombus of the central vein, brings evidence to show that the most frequent cause of the clinical picture is an endo-phlebitis proliferans. Out of the cases reviewed, in only two was the central vein thrombosed, and these were septic cases. A coagulum due to the fixing agent may resemble a thrombus, but in the majority of the cases the evidence was insufficient to show that it was due to thrombus, but rather indicated that it was due to an endo-phlebitis proliferans. The obstructing mass showed no blood remains, such as blood pigment, and the adventitia around the obstruction showed no signs of inflammation, but the mass consisted either entirely of connective tissue or partly of proliferated endothelial cells. The anatomical examination of all the cases save one showed the presence of glaucoma. In one of Verhoeff's cases acute glaucoma set in three weeks after the onset of the symptoms of obstruction of retinal vein. The eye had to be enucleated for pain and showed, on examination, an absence of a thrombus, and the presence of complete occlusion of the vein due to an endo-phlebitis proliferans. There was no cupping of the disc, but the glaucoma seemed to have been due to excess of albumen in the vitreous, derived from the retinal veins and capillaries. This excess of albumen was shown by the vitreous being found coagulated by the action of the formalin, when the eye was divided. Conclusion.—Complete obstruction of the central vein, with classical ophthalmoscopic picture of thrombosis of this vessel, may be produced by endo-phlebitis proliferans without thombosis. The proliferation may involve the sub-endothelial tissue alone, or the obstruction may be completed by a more active endothelial proliferation into the lumen. All of the cases anatomically examined in which obstruction of the central retinal vein has been attributed to non-septic thrombosis can be explained by, and in all probability were due to, endo-phlebitis proliferans alone. In certain cases obstruction of the central retinal vein may early give rise to acute glaucoma. M.

Medical News in Brief.

Liverpool School of Tropical Medicine.

Sir Alfred Jones presided at a dinner given on July 15th, at Liverpool, for the purpose of bidding farewell to Dr. J. L. Todd (late director of the Tropical Research Laboratories at Runcorn), who is returning to Canada, and to bid God-speed to Dr. Barrett and Dr. Yorke, members of the Black Water Fever Expedition, who are going out to Africa. The company included the Bishop of Liverpool, Lord Mountmorres, Sir Rubert Boyce, F.R.S., Professor Ross, C.B., Professor Carter, Dr. Caton, the American Consul (Mr. Griffiths), and the Mexican Consul-General in Liverpool. Sir Alfred Jones and Sir Rubert Boyce spoke to the toast of farewell to Dr. Todd, the latter remarking that the doctor was the finest example of an Imperial student. Coming from Canada, he had been willing to work in every part of our Empire, and, while giving his time and talents, he had also contributed something like £200 per annum to the Tropical School, and, more particularly, to found the institution at Runcorn, where the best scientific work had been done. He (Sir Rubert) hoped that that institution would be firmly united to the Liverpool School of Tropical Medicine. He would also like to see another expedition sent out in connection with sleeping sickness, for having, they believed, found the means of preventing that disease, it was their duty to push the treatment as much as possible. Dr. Todd said that the school had shown very little gratitude for the work of Dr. Dutton, who died whilst engaged in research work. They had tried to collect sufficient to establish a professorship in his honour, but of the £16,000 required only £4,000 had been received. The Bishop of Liverpool proposed success to the Black Water Fever Expedition, and paid a high tribute to the work of the School of Tropical Medicine, which, he said, had been wonderfully successful in enabling European civilisation and Christianity to lay hold of peoples who some time ago knew them not. It was highly satisfactory that London and Liverpool joined hands in sending out that expedition. Professor Ross supported the toast, which was acknowledged by Drs. Barrett and Yorke. On the motion of the American Consul, the toast of "The Study of Tropical Medicine" was honoured, and was responded to by Colonel Bruce, who said that the Mediterranean fever, which had been the dread of the Army at Malta, had practically been blotted out.

Joint Stock Companies and the Practice of Dentistry.

Judgment has been given during the past week in the Irish Courts in a case of very great interest and importance to the medical and dental profession. The case which was heard some weeks ago has been already mentioned in these columns. In brief, it consisted in an application by the Attorney-General at the relation of Mr. Kevin O'Duffy, Hon. Secretary of the Irish Dental Association, claiming an injunction to restrain Myddleton, Limited, a Belfast company, and its members from practising as surgeon dentists, and the directors from permitting the company to remain on the registry of Joint Stock Companies.

Mr. Justice Barton, in giving judgment, said in applying to the present case the authorisation which had been cited during the hearing, the particular form and character of this proceeding had to be borne in mind, as well as the peculiar nature of the rather scanty evidence which the plaintiff had laid before the Court. He could not say that the memorandum of association in this case was open to legal objection. The title of the company did not contain the word dentist or any of its synonyms, or any allusion to dentistry. The principal purpose of incorporation was to carry out dental operations by means of properly qualified persons—a purpose which is not *per se* illegal. If the company were to carry out dental operations by means of unqualified persons, serious questions might arise, including the question of *ultra vires*. But there was no evidence in this case upon that question of fact. The Court did not know who had carried out the dental operations of the company. Therefore the plaintiff claimed wider relief than the evidence justified. The plaintiff, had, however, established his right to the relief claimed in restraining the defendants from registering the company as dentists. In conclusion, the judge said: "I am disposed to think that defendant's counsel endeavoured to form upon Jaffe's case a larger claim of privilege for companies than the decision in that case will support. They claim for limited companies as a result of that case an unobstructed right to use the word, 'dentist,' or its synonyms in any and every shape and in any and every context. Jaffe's case decided that the word 'person,' in Section 3 of the Dentists Act, 1878, does not include individual persons, and that the Section hits individuals but does not hit limited companies. But a company, although it may be exempted from the penalties imposed by that Section, is not, in my opinion, thereby privileged to make false representations which are calculated to mislead the public as to the qualifications of the individuals whom it composes or employs. There will be an injunction to restrain the defendant company and the directors and members thereof from employing the defendant Alfred Myddleton under the title of surgeon dentist or dentist, to carry on business under the memorandum of association of the said company, and from holding forth or representing in the register of directors and managers, or the reports or returns pursuant to the Companies Act to the registrar of joint stock companies, or in their advertisements to the public, or otherwise, or elsewhere that the defendant Alfred Myddleton is a dentist, or that the defendant company comprises or employs persons of the name of Myddleton who are dentists. The plaintiff had practically succeeded, and if he had limited his claim he would be entitled to the whole costs of the action. The order as to costs will be that the plaintiff shall have the costs of the action save in so far as they may have been increased by the relief claimed in other parts of the statement of claim."

Society for the Relief of Widows and Orphans of Medical Men.

At the quarterly Court of Directors of this Society, held on July 10th, Dr. Blandford, President, in the chair, twenty-one directors were present. The deaths of Sir William Broadbent and Dr. Robert Barnes were reported; both had held the office of director. The Secretary was directed to send letters of condolence to Lady Broadbent and Mrs. Barnes. Two new members were elected. Since the last quarterly Court one of the widows, an annuitant of the charity, had died. Her husband paid a life subscription fee of £26 5s., and the widow had received in grants the sum of £490. Six letters had been received from widows of medical men, asking for relief, but in each instance this had to be refused as their husbands had not been members of the Society. The sum of £1,300 10s. was voted for the half yearly grants to the 49 widows and 20 orphans, at present on the books of the Society. Membership is open to any registered medical practitioner, who at the time of his election is residing within a twenty-mile radius of Charing Cross. Full particulars may be obtained from the Secretary at 11 Chandos Street, Cavendish Square, London.

Ulster Medical Society.

At the annual meeting of the Ulster Medical Society, the President, Dr. Gaussen (Dunmurry), in the chair, Dr. Howard Stevenson, the honorary secretary, read the annual report of council. Dr. Fielden, honorary treasurer, presented the statement of accounts, showing a balance in favour of the society of £30 10s. 8d., and Dr. Storey, honorary librarian, presented the library report. The following were elected office-bearers for the ensuing session, 1907-8: President, Dr. John McCaw, Senior Physician to the Belfast Hospital for Sick Children; Vice-Presidents, Dr. A. Fullerton and Dr. Wallace; Treasurer, Dr. Fielden; Librarian, Dr. Storey; Secretary, Dr. Howard Stevenson; Editing Secretary, Dr. Rankin; Council, Drs. R. J. Johnstone, T. Houston, S. A. Craig, A. G. Robb, W. St. C. Symmers, W. B. McQuitty.

North-East London Post-Graduate College.

A vacation course will be held at the Prince of Wales' General Hospital, Tottenham, during the coming September, commencing on the 9th of the month, the arrangements for which have been adapted to the requirements of those engaged in active practice. They include daily cliniques in the wards, demonstrations in the out-patient and special departments, classes on clinical methods. Other practical clinical demonstrations and clinical lectures with lantern demonstrations. The fee for the course, which will last a fortnight, is one guinea. Further particulars of the course may be obtained from the Dean of the Hospital.

Royal College of Surgeons in Ireland: Fellowship Examinations.

Notice is hereby given that on and after January 1st, 1910, all examinations for the Fellowship of this College will be conducted under the scheme of examination now known as Grade I. No candidate after the above date will in any circumstance be admitted to examination for the Fellowship of this College under the scheme now known as Grade 2, which will then cease to be used.

The United Services Medical Society.

At the first meeting of the Council of this newly-formed Society, it was decided that meetings be held at the Royal Army Medical College at 8.30 p.m. on the second Thursday in each month, commencing on October 10th, 1907; that the annual subscription be 5s., payable in advance; and that a notification of the formation of the society accompanied by an invitation to join be sent to all medical officers on the active lists and to those on the retired lists whose addresses can be discovered. Should any medical officer on the active or retired list of the Navy, the British and Indian Armies, or the Auxiliary and Colonial Forces not receive an invitation, the Council hope that, if desirous of joining the society, he will communicate with one of the honorary secretaries, Fleet-Surgeon W. W. Pryn, R.N., "Tredown," 25 Idmiston Road, West Norwood, S.E., or Lieut.-Colonel C. H. Melville, R.A.M.C., Royal United Service Institution, Whitehall, S.W.

PASS LISTS.

University of Glasgow.

The following candidates have passed the fourth (final) professional examination for M.B., Ch.B. The names are arranged alphabetically.

W. W. Adamson, G. V. Anderson, A. H. Arnott, David Arthur, B.Sc., Herbert Bertram., R. L. Binning, William Brown, M.A., B.Sc., James Cairncross, T. H. Campbell, R. P. Cartwright, T. G. Copestake, A. J. Couper, A. D. Cowan, J. R. Craig, C. A. Crichlow, Neilson Davie, H. W. Dempster, J. A. Doctor, Donald Duncan, W. H. Duncan, Allan Dunsmuir, L. J. Dunstone, A. W. Eadie, W. M. Elliott, A. Fairley, T. H. Forrest, Thomas Forsyth, Berkeley Gale, George Garry, James Gemmell, David Gibson, H. M. Granger, J. V. Grant, T. P. Grant, W. C. Gunn, Lawrence Hislop, Archibald Hogg, A. J. Hutton, C. L. Kerr, A. T. I. Macdonald, Neil MacInnes, M.A., Robert McInroy, J. B. Mackay, T. C. Mackenzie, A. D. M'Lachan, D. C. Maclachan, A. N. R. M'Neill, C. J. C. Macquarie Carswell Marshall, J. H. Martin, Horatio Matthews, W. S. Melville, J. C. Middleton, M.A., B.Sc., J. W. Miller, Thomas Miller, M.A., J. R. Mitchell, Hugh Morton, James Muir, R. C. Muir, Patrich O'Brien, D. M. Reid, Donald Renton, M. M. Rodger, T. D. C. Ross, Alexander Scott, J. M. Smith, John Steedman, C. K. Stevenson, M. J. Stewart, Lawrence Storey, J. A. Struthers, J. M. Taylor, R. S. Taylor, D. A. Thompson, M.A., H. J. Thomson, J. A. Thomson, Robert Todd, John Turnbull, Martin Turnbull, W. B. Watson, John Weir, F. R. Wilson, Samuel Wilson, M.A., W. M. T. Wilson, Thomas Winning, M.A., G. Yeghia Yardumian Matthew Young.

Women.—Jeannie Montgomery Andrews, Martha Maclean Buchan, Margaret Gardner Forrest, Ella Smith Hill, M.A., Annie M'Crorie, Janet Annie Macea, Jessie Deans Rankin, M.A., B.Sc.; Jane Isabel Robertson, M.A.

The following passed with distinction in the subjects indicated:—

In (*a*) Surgery and Clinical Surgery (*b*) Practice of Medicine and Clinical Medicine—David Arthur, B.Sc., Hugh Morton, Matthew John Stewart.

In (*a*) Surgery and Clinical Surgery (*b*) Midwifery—William Cooper Gunn.

In Surgery and Clinical Surgery.—Jeannie Montgomery Andrews, William Brown, M.A., B.Sc., Martha Maclean Buchan, Thomas Hay Campbell, James Robert Craig, Charles Adolphus Crichlow, Donald Duncan, William Marley Elliott, Archibald Fairley, Margaret Gardner Forrest, Samuel Nicol Galbraith, Berkeley Gale, James Wilfred Georgeson, Henry Maxwell Granger, Thomas Purdie Grant, James Dow Gray, Ella Smith Hill, M.A., Archibald Hogg, Andrew James Hutton, Thomas Miller, M.A., Daniel M'Kinlay Reid, George Waugh Scott, John Steedman, Campbell Kay Stevenson, Lawrence Storey, David Alexander Thomson, M.A., Hugh Johnstone Thomson, Samuel Wilson, M.A., Matthew Young.

In Practice of Medicine and Clinical Medicine—John M'Vittie, Horatio Matthews.

In Midwifery—Allison David M'Lachlan, Alexander Scott.

Royal College of Surgeons of Edinburgh.

The following gentlemen, having passed the requisite examinations were, at a meeting of the College held on the 16th inst., admitted Fellows:—Edward Archer-Brown, M.B., M.R.C.S. Eng., L.R.C.P. Lond., Johannesburg; William Bruce Bell, M.B., C.M., Manchester; Alexander Glover Coullie, M.B., Ch.B., Pencaitland; David Elliot Dickson, M.B., C.M., Lochgelly; William Arnott Dickson, M.B., Ch.B., Lochgelly; Henry Tristram Holland, M.B., Ch.B., Baluchistan; William Leonard Maccormac, M.B., Ch.B., London, S.W.; Archibald McKendrick, L.D.S., L.R.C.S.E., Kirkcaldy; Charles Edmund Russel Rendle, M.R.C.S. Eng., L.R.C.P. Lond., Plymouth; Herbert Wilkinson Riggs, M.D., C.M., Vancouver; Geoffrey Allen Upcott-Gill, M.R.C.S. Eng., L.R.C.P. Lond., London, N.W.; and William Young, M.B., C.M., Major, Indian Medical Service.

Society of Apothecaries of London.

The following candidates, having passed the necessary examinations, have been granted the L.S.A. Diploma of the Society, entitling them to practise Medicine, Surgery, and Midwifery:—E. R. Bastard, M. L. Ford, A. J. Hopper, R. J. W. McKane, G. B. Messenger, E. E. C. Vollet, and J. S. Ward.

NOTICES TO CORRESPONDENTS, &c.

☞ **CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.**

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

A LAYMAN.—We cannot publish letters from laymen when they are evidently not inspired by public spirit, but rather prompted by private feelings of malice or spite.

QUOD.—Medical men's ordinary earnings from practice and appointments will, of course, be chargeable on the ninepenny basis, but it is the individual's own responsibility to see that he gets the abatement. Unless the claim is made the surveyor, with the usual red-tape methods of administration, will not be bound to call the taxpayer's attention to his rights. A special form (which we are advised is not yet available) is being printed, and will be distributed at the surveyor's pleasure, but if it is not sent in by September no allowance will be made. Your best plan then will be to write to your surveyor and make his life a burden till you get a form out of him.

THE TREATMENT OF HAIRY MOLES.

QUERY writes:—"I should be glad if any of your readers could tell me briefly what is the best treatment for hairy moles in a girl aged 11, the moles being situated on the face, and the parents not sufficiently well off to send her to a specialist or even to town for hospital treatment. Have X-rays been of any value in this condition?"

MR. EDWARD B.—The marked communication reached us as we were "at press," too late for reference in present issue.

COUNTRY PRACTITIONER.—Possibly enemata, or suppositories of glycerine would be found beneficial.

R. P.—There are several agencies that deal in the placing of resident patients with medical men. Some of them are very shady affairs and some quite straightforward. The Association of Medical Men receiving Resident Patients is clearly the one that appeals most directly to medical men, as it is entirely worked by medical men, and aims merely at being self-supporting. The address of the hon. secretary is 56, Outer Temple, Strand, W.C.

PLAGUE IN INDIA.

DR. RUTHERFORD last week asked the Secretary of State for India what was the number of deaths from plague during June in the Punjaub and in the whole of India; and what was the total for the six months in the Punjaub and in India.

Mr. Morley's reply was that the figures for June were:—Punjaub, 58,821 deaths; whole of India, 69,064. For six months ended June:—Punjaub, 632,953; whole of India, 1,060,067.

ERRATA.—In the paper published in our last issue entitled "Some Further Reflections on Cancer and Its Treatment," by J. A. Shaw-Mackenzie, M.D.Lond., at page 62, column 2, par. 3, line 10, " . . . animal tissues and organs. I have . . ." should read " . . . animal tissues and organs, I have . . . ." Page 63, column 1, par. 5, line 4 from bottom, " . . . fœtal secret*ion* . . . " should read " . . . fœtal secretin . . ."

SUBSCRIBER (London, S.E.)—We are glad to be able to ease your mind by saying emphatically that the institution you are interested in was not referred to.

MEDICUS.—Thank you for your letter and cutting. The matter is an important one and we hope to deal with it next week.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JULY 24TH.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—2.30 p.m.: Skin (Dr. Meachen), Eye (Mr. Brooks), Medical Out-patient (Dr. Whipham).

THURSDAY, JULY 25TH.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND (11 Chandos Street, Cavendish Square, W.).—9.30 a.m.: Council Meeting. 11 a.m.: Annual Meeting. Election of Officers and Council. 2 p.m.: Address:—The President (Dr. P. W. MacDonald). Paper:—Dr. C. C. Easterbrook: The Sanatorium Treatment of Active Insanity by Rest in Bed in the Open Air. 7.15 for 7.30 p.m.: Annual Dinner at the Whitehall Rooms, Hotel Metropole.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques:—Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson). 3 p.m.: Medical In-patient (Dr. Chappel).

FRIDAY, JULY 26TH.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND (11 Chandos Street, Cavendish Square, W.).—11 a.m.: Discussion on Psychiatry as a Part of Public Medicine (introduced by Dr. T. S. Clouston). Clinical Demonstration and Paper:—Dr. A. Wilson: The Psychology of Crime. Paper:—Dr. H. Devine: A Case of Katatonia in a Congenital Deaf Mute (illustrated with lantern slides). 2 p.m.: Communication.—Dr. W. F. Robertson and Dr. G. D. McRae: Observations on the Treatment of General Paralysis and Tabes Dorsalis by Vaccines and Anti-sera. Paper:—Dr. L. C. Bruce: Clinical Observations on Certain Cases of Mental Depression.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—9.30 a.m.: Clinique:—Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. Leslie).

Vacancies.

York Dispensary.—Resident Medical Officer. Salary, £190 a year, with board, lodging, and attendance. Applications to W. Draper, Esq., De Grey House, York.

The Cambridgeshire, etc., Asylum.—Second Assistant Medical Officer. Salary, £120 per annum, with board, lodging, and attendance in the Asylum. Applications to T. Musgrave Francis, Clerk to the Visitors, 18 Emmanuel Street, Cambridge.

Bradford Children's Hospital.—House Surgeon. Salary, £100. Applications to C. V. Woodcock, Secretary, Bradford.

Carmarthenshire Infirmary.—Resident Medical Officer. Salary, £100 per annum, with furnished apartments, board, attendance, fire, gas, and washing. Applications to Howell Howell, Secretary.

Salford Union.—Male Resident Medical Officer. Salary, £130 per annum, with furnished apartments and attendance. Applications to F. Townson, Clerk to the Guardians, Union Offices, Eccles New Road, Salford.

The Guardians of the Leeds Union.—Assistant Medical Officer. Salary, £120 per annum, with board, washing, apartments, and attendance. Applications to Jas. H. Ford, Clerk to the Guardians, Poor Law Offices, South Parade, Leeds.

Tunbridge Wells General Hospital.—House Surgeon. Salary, £100 per annum, together with board, furnished apartments in the Hospital, gas, firing and attendance. Applications to the Secretary.

Hospital for Sick Children, Great Ormond Street, London, W.C.—House Physician, House Surgeon, Assistant Casualty Officer. Stewart Johnson, Secretary. (See advt.)

Royal Southern Hospital, Liverpool.—Resident Pathologist and Registrar. Salary, £100, with board and residence. Applications to the Superintendent.

Appointments.

DIMOCK, HORACE, M.B., B.C.Cantab., M.R.C.S., L.R.C.P.Lond., Assistant House Surgeon at Addenbrooke's Hospital, Cambridge.

DOWLING, E. A. G., L.R.C.P., M.R.C.S., L.D.S., Lecturer in Dental Anatomy, Physiology and Dental Histology at University College, Bristol.

ELGOOD, OLIVE, M.S.Lond., Honorary Anæsthetist to the Birmingham and Midland Dental Hospital.

EVANS, WILLIAM OWEN, L.R.C.P., L.R.C.S., L.M.Edin., L.F.P.S. Glasg., District Medical Officer and Medical Officer to the Workhouse by the Pontardawe (Glamorganshire) Board of Guardians.

EYRE, J. W. H., M.D., M.S.Durh., Bacteriologist to Guy's Hospital.

FRIEND, JULIUS, L.S.A., Medical Officer to the No. 2 District by the Leeds Board of Guardians.

HITCHCOCK, NORMAN, M.B., B.S.Lond., M.R.C.S., L.R.C.P.Lond., Resident Medical Officer to the Brixton Dispensary.

JONES, JOHN ARNOLD, M.B., Ch.B.Vict., F.R.C.S.Edin., Honorary Assistant Aural Surgeon to the Manchester Eye and Ear Hospital.

LOCHRANE, FRANK J., M.D., B.S.Glasg., Honorary Gynæcologist to the Derbyshire Royal Infirmary.

McEWAN, PETER, M.B., Ch.B., F.R.C.S.Edin., Resident Surgical Officer at the Bradford Royal Infirmary.

PEDLEY, F. NEWLAND, F.R.C.S.Eng., L.D.S., Consulting Dental Surgeon to Guy's Hospital.

PERRY, FREDERICK W., L.D.S., Demonstrator in Dental Anatomy, Physiology and Dental Histology at University College, Bristol.

PILLIN, H. L., L.D.S., R.C.S.Eng., Dental Surgeon to Guy's Hospital.

PRICE, HENRY J., F.R.C.S.Eng., Medical Referee under the Workmen's Compensation Act, 1906, for County Court Circuit No. 38, and to be attached more particularly to Braintree, Chelmsford, Colchester, Dunmow, Halstead, Harwich, and Maldon County Courts.

Births.

HUDSON.—On July 19th, at Sarratt Hall, Sarratt, Herts, to Dr. and Mrs. Hudson, a daughter.

NEWBOLT.—On July 16th, at 42, Catharine Street, Liverpool, the wife of George Palmerston Newbolt, F.R.C.S., of a daughter.

PERIGAL.—On July 15th, at Blenholme, new Barnet, Herts, the wife of Arthur F. Perigal, M.D., of a daughter.

Marriages.

AYERS—SHACKLETON.—On July 18th, at St. Bartholomew's, Sydenham, the Rev. Frank Ayers, M.A., Vicar-Designate of St. Michael's and All Angels', Sydenham, to Ethel Rose, third daughter of Henry Shackleton, M.D., West Hill, Sydenham.

COCKE—ATKINSON.—On July 17th, at St. Paul's Church, Crewe, Thomas Dudley, eldest son of the late Thomas Henry Cocke and Mrs. Cocke, of 84, Harley Street, to Mirion, third daughter of Dr. and Mrs. Atkinson, J.P., of Mirion House, Crewe.

Death.

JEAFFRESON.—On July 21st, at the Hostel of St. Barnabas, 31, Harman Street, Hoxton, London, Jemima, second daughter of the late John Furrance Jeaffreson, F.R.C.S., of Canonbury Lane, London.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXV. WEDNESDAY, JULY 31, 1907. No. 5

NOTES AND COMMENTS.

The Work Cure.

THAT fashion in treatment varies nearly as much as fashion in ladies' hats is an undeniable fact, but it may be hoped that whereas the latter leads nowhere, the former is showing a rational and upward tendency. The Weir-Mitchell cure is certainly not as popular, at all events with patients, as it was a few years ago, and, in searching for a successor, it may be that an excursion in precisely the opposite direction will be healthful and healing. Already in sanatoriums for consumptives, notably at Frimley, the value of work is beginning to be demonstrated, and there is no doubt that in asylums a great many improvable patients are a great deal better occupied in practising mechanical handicrafts than in lounging about watching cricket-matches. Some very interesting experiments are reported from Vienna of the value of work at the State Institution for Mental Diseases at Mauer Oehling. Dr. Starlinger, the superintendent, has more than half his patients at work of some kind—agricultural, dairy, farm, or mechanical. Moreover, for those of a literary turn he gives facilities for the production of a newspaper, and a periodical largely written and composed by the patients is published in the asylum. We have not had the advantage of seeing a copy, but we can imagine it would be sufficiently entertaining to rank, let us say, with *Punch*. The important point is that all this work is of great benefit to the inmates, and the work-cure may eventually invade our shores as successfully as the rest-cure did ten years ago.

Sir Thomas Fraser Redivivus.

SIR THOMAS FRASER, like Lord Brougham and Mark Twain, has had the curious experience of seeing himself killed before his own eyes, though he has not, we believe, shared with Sir Harry Parkes and a few other eminent people the exquisite enjoyment of assisting at his newspaper post-mortem. The mistake arose in the Lord Chamberlain's office, it seems, in the same way that most mistakes and injustices arise in government departments, namely, by junior clerks doing the work for which their seniors are supposed to be responsible. We should have thought that even junior clerks would have had at their command sources of information with regard to eminent men which would have enabled them to verify such important facts as to whether they were alive or dead; indeed, it is inconceivable that two minutes' conversation on the telephone with the Scottish Office would not have brought authentic news. For our own part, we were led by the Lord Chamberlain's information to announce that Sir Thomas Fraser had been succeeded by Sir Thomas McCall Anderson in the office of physician to the King in Scotland, whereas, of course, he had only been joined in that office by Sir Thomas, who succeeded the late Sir William Gairdner. As there had been other changes in the King's medical attendants, we hoped that the announcement was preliminary to even higher honours. At any rate, we trust that he will be spared for many years to enjoy the marks of confidence he has deservedly earned from the Sovereign.

County Courts and Debt Collecting.

A LETTER opening up a question of much importance to medical men appears in our correspondence columns this week. It seems that Judge Mulligan, K.C., who has recently been raised to the bench, has started by reversing the practice of his predecessor, and we believe of most if not all County Court judges of the present day, with regard to the collection of small debts. Now, there are few medical men with a large *clientèle*, especially in scattered and unsettled districts, who are not compelled to make use of the County Court more or less frequently to get in their small debts. The total these small amounts reach in the course of a few years is sometimes astonishing, and in self-defence most medical men have to take steps with regard to them, if only to get rid finally of undesirable patients who call them up at all sorts of hours and never pay their bills. Now the collection of trivial debts by the full legal process is an expensive and inefficient method, and though no one grudges paying a solicitor for advice and work, it is ridiculous that his costs for proceeding in the case of a small debt should amount to more than the debt itself, and that the money should frequently never be recovered after all. It is like using a steam-hammer to crush a fly. Of late years, a class of debt-collectors have sprung up who work entirely on commission, and who, by means of calling on debtors, are frequently able to make some arrangement with them whereby instalments may be paid with reasonable regard to the amount and frequency of their wages. The remuneration of the debt-collector is very small, but he is able, by making a speciality of his business to get a living out of it. The debt-collector is an honourable man, as a rule, and is a good friend to doctor and poor alike.

Judge Mulligan and Paid Agents.

When a debtor has been found impervious to argument and it is decided to proceed by means of the County Court, it is a great convenience for a medical man to leave everything in the collector's hands and not to have personally to appear in undisputed cases. Indeed, a common practice is for a collector to arrange with a debtor as to when and how the debt shall be paid, and, having got his formal acknowledgement, to appear in Court and obtain an order to that effect. Now Judge Mulligan has decided to sweep away all this practice, and he is refusing to hear collectors who appear before him. He speaks of the previous custom as a "nefarious practice," which he will not permit. Now, if his Honour had given some reason for his action it might have been possible to understand why he should regard it, the custom of his predecessor and his senior colleagues, as nefarious, but all we can gather from a lengthy report of some proceedings in his Court is that he regards it as very wrong for a paid agent, not a solicitor, to appear for anyone else. As reasonable beings we cannot think why it should be "nefarious" to pay an agent not a solicitor to appear in Court, and not equally nefarious to pay a solicitor. As a matter of fact it seems to be simply and solely a question of solicitor's privilege. A lawyer does not like irregular practitioners to appear in Court any more than a doctor likes an irregular practitioner to practise medicine, and we should certainly wish to support the lawyer in such a claim if it were not for certain points of public policy.

Lawyers and Collectors.

As law-courts and lawyers are made for the public, it stands to reason that if they are not able to do the public work, the public must make other arrangements. This is what has happened with regard to petty debt-collecting. It is in spite of the lawyers, who did not find it worth their while to organise the work on a large scale, that creditors have been able to get in petty debts, and no doubt it is hardly solicitor's work to spend days and weeks getting in half-crowns and five-shilling bills, many cases involving several visits and letters. In fact, if Judge Mulligan has his way, small debtors will enjoy their previous immunity again. In these circumstances we cannot see why it should be proposed to forbid collectors of good character to appear in court in purely formal and uncontested cases to prove debts. Only a fortnight ago, in the Clerkenwell County Court, a company sent one of its employees to conduct a disputed case on its behalf, and Judge Edge held that he ought to allow him to give his evidence of the debt—which is all the debt collector wants—though he would not allow him to examine and cross-examine. If Judge Mulligan, who has yet to earn his experience on the bench, proposes to be a law unto himself, there will have to be found means for testing the value of his decision.

Notification of Consumption.

Dr. J. F. J. Sykes, medical officer of health, in a recent report issued :—"The experience of St. Pancras during the time that voluntary notification of consumption has been in force appears to coincide with that of nearly all other local authorities which have adopted the same course. This experience is that voluntary notification is ideal in theory, but of little value in practice, because the number of cases notified is very small, and the notifications often take place when the patients are moribund."

LEADING ARTICLES.

THE CAMPAIGN AGAINST QUACK MEDICINE.

The evil wrought by the yearly increasing sale of quack medicines has assumed the dimensions of a national scandal. Vast sums of money are expended annually in advertising nostrums claiming to cure the incurable and to work miracles that are clearly outside the range of human achievement. In other words the claims of the vendors are false, therefore their business is a fraud, and the newspapers that accept their advertisements are participating in the proceeds of a fraudulent transaction. That is the plain English of the matter. Worst of all, this traffic is sanctioned by the State, which draws a paltry yearly revenue from patent medicine stamps. This, be it remembered, is the great, omniscient State that jealously insists upon the thrice-tested knowledge of its qualified medical practitioners, but none the less allows its subjects to be fleeced on all hands by quacks and nostrum-vendors. This, too, is the paternal State that wrings its hands in despair at the physical degeneracy of our race, at the high infantile mortality, and the unnecessarily high death rates of many of our great towns. It would be interesting to speculate on how much of that physical degeneracy, and how many of those wasted lives are due to quacks and quackery. Some day the State will doubtless wake up and expel the enemy that is within our gates. Then we shall probably have the Royal Commission of Inquiry into quacks and quackery that has been for some time past demanded in season and out of season by The Medical Press and Circular. Happily signs are not wanting that the conscience of the nation is being slowly awakened to this great evil. The matter is now and then dealt with forcibly by Coroners who are brought face to face with many of the disasters directly caused by this nefarious traffic. The judges of the land occasionally utter a scathing denunciation when a case of quackery comes within their jurisdiction. The matter, again, is discussed freely in medical journals and in medical societies in all parts of the world. But perhaps the most significant movement is the revolt of the dispensing chemists against proprietary and secret remedies. Last week the Federation of Local Pharmaceutical Associations met in Manchester and listened to a capital paper by Mr. J. Cofman, of London. For downright plain speaking this gentleman's essay would be hard to beat. He divides "proprietary" into three classes, of which one includes what may be called the more respectable articles, the composition of which is no secret, but which represent genuine drugs prepared by special methods, and not sold under false colours. A second group deals with "frauds that have somehow escaped the courts of law, all of secret composition and claiming to cure every imaginable disease." "To stock and to sell these quack medicines," says Mr. Cofman, "is a disgrace for a respectable person." The third class is that of old or well-known drugs or compounds claiming special virtues under the ægis of some particular name. These "proprietaries" are spoken of as "in the highest degree injurious to the present interest, and to the future interest of pharmacy." The author of this vigorous onslaught invokes the co-operation of the Pharmaceutical Society and of the General Medical Council in the attempt to secure legislation for the proper control of the traffic in secret remedies. There can be little doubt that if the chemists decide to fight this great evil the proprietors of the baser sort of proprietory remedies will find their trade seriously threatened, if not, in many instances, altogether destroyed. As far as the policy of this journal is concerned we can only say that we shall welcome the powerful aid of the pharmaceutical societies in fighting what we regard as a national scandal. There is admittedly a material interest concerned in the case of the chemists, but there is no reason to assume that their motives are on that account less straightforward and honourable than those, let us say, of the medical profession. If the pharmaceutical chemists resolve to rid their profession of this unclean thing, they would earn the esteem of all right thinking men. Should they form a strong policy and a strong organisation they will find abundant opportunity of distinguishing themselves in a resolute campaign that must sooner or later be undertaken.

CURRENT TOPICS.

The British Medical Association and the General Medical Council.

For many years the British Medical Association has been debating the question of taking on the functions of a defence society on behalf of its members, but various obstacles, legal and otherwise, have stood in the way. Although there is some doubt as to whether the Association has so far officially authorised actions appertaining to a defence society, one of its many committees has assumed authority in the matter, and proposes to appear as prosecutor in penal cases before the General Medical Council. The Council of the Association has declined to express any opinion as to the powers of the committee so acting, and the position at present is one of much confusion. The only tangible result is that Professor Saundby and some other members of the General Medical Council who were also members of the Association, have cut their connection with the latter. Whether it be wise or not for the Association to take on such duties in defence of its members is a matter for themselves, but obviously if it is to be done it should be done regularly and formally, and members should know where they stand. It is not for an irresponsible sub-committee to decide a great question of policy for an association of several thousand members. Moreover, in the present state of the by-laws of the Association, it is very doubtful if money can be legally spent in the prosecution of cases before the General Medical Council. It is to be hoped that the Representative Meeting this week will come to some authoritative decision.

Fourth of July Fatalities.

Though the full records of the Fourth of July fatalities in the States are not yet available, it is to be feared that the tale of victims will be nearly as great as in previous years. Year after year the medical and some lay journals have preached against the insane antics to which the patriotic youth of the country gives itself up on the national anniversary, but, except in one particular, their preaching has had little effect. Toy-pistols, fire-crackers, noise-producers of all sorts, are as much in vogue as ever. And year after year the national anniversary claims its hecatomb of human victims. One of the Chicago papers, appearing on the morning of the 6th, was able to report 59 fatal accidents and 3,807 injuries which had occurred during the previous two days. In Pittsburg alone, 15 violent deaths occurred during the celebration of the national festival. The one particular in which for the past few years there has been progressive improvement is the incidence of tetanus. Only five or six years ago tetanus was a common sequel of comparatively trivial wounds received from toy explosives. The medical journals, by teaching that all wounds of the sort should be treated by the open method, have succeeded in reducing the mortality from this disease to a very low figure.

The Effects of "Belated Ovaries."

The complete reversal in the treatment of certain uterine diseases, which has led operators to discard principles which lead to the removal of the ovaries and the retention of the uterus, in favour of principles which lead to the removal of the uterus and the retention of the ovaries has been amply justified by its results. In consequence, there are now but few gynæcologists, and their number is rapidly diminishing, who do not recognise the extreme importance of retaining in every possible case even of a portion of an ovary. We publish in to-day's issue a clinical lecture from the pen of Mr. J. Bland-Sutton on this important subject. His views are in entire accordance with the most recent gynæcological opinions, and his practical experience is very welcome as a means of convincing the few who still remain satisfied with the older teaching.

An Open-Air Schoolroom.

A novel and interesting experiment is being conducted by the London County Council in the shape of an open-air school, opened last week at Plumstead. The scheme is carried out in connection with the Woolwich group of special schools. The children have been selected from certain schools in Woolwich, Greenwich, and Deptford, and admission is granted only to those who are suffering from anæmia or from tuberculous affections. There were no less than 300 applications from parents for the 120 vacancies. In fine weather the children recline in deck chairs in the open, while a well-built shelter is provided for use in rainy weather. This new departure is in touch with the teachings of modern medicine, and its wider application to healthy children, were that possible, would be a desirable thing. Clearly it is far better to cure children in an open-air school rather than to have to attempt the same thing in a sanatorium under the less promising conditions of later life.

The Hygiene of the Swimming Bath.

Now that public swimming-baths are being adopted throughout the country, it is well to raise a note of warning as to their hygienic aspects. There is no need to insist that water should be renewed at frequent intervals, and that the bath should be emptied periodically and cleansed throughout, for we understand that such measures are already carried out. Clearly, however, the frequency of renewal of the water should be regulated by the number of bathers. Some public baths are immensely popular on cheap nights in the hot weather, and are patronised by hundreds of persons. Under such circumstances it would be obviously desirable to provide a rapid and continuous stream of water in and out of the bath. Another point is that bathers should be obliged to wash their feet, and obviously uncleanly persons should be thoroughly douched before going into the bath. Spitting should be punishable by expulsion, and a fine. In some parts of the Continent, such as Frankfort, regulations of the kind are enforced without any friction. The careful consideration of municipal authorities may be devoted with advantage to the hygiene of the bath. Nor is it less necessary in many instances on the part of those who are in charge of the cleansing operations of our poor-law institutions, barracks, prisons, and reformatories.

Fees for Certificates under Workmen's Compensation and Education Acts.

Under the new Workmen's Compensation Act, there must inevitably arise a great many cases in which medical certificates are necessary either in the prosecution or the defence of claims. Medical men, therefore, will do well to insist that an adequate fee is paid for their signature to every document of the kind, and it seems not unlikely that the scale of future remuneration will be to a great extent determined by their first stand in the matter. The Council of the Irish Medical Association has issued broadcast a resolution advising all medical men to refuse any certificate in connection with the Workmen's Compensation Acts until payment has been guaranteed. The same body also advises refusal of certificates under the Education Act, until reasonable remuneration be granted. As regards the latter Act, it is certain that local authorities get a good deal of gratuitous service out of the medical profession on various pretexts. They demand, for instance, certificates for hospital patients suffering from ringworm, whooping-cough, and other infectious diseases. Quite recently a healthy child was brought to an out-patient department with a request for a certificate that he was in a state of good health. Unless medical men are warned in time they will quite possibly drift into a similar position as gratuitous (although, be it noted, indispensable) advisers under the Compensation Act.

Medical Referees and Workman's Compensation.

It will be of much interest to medical men to see how the new medical arrangements under the Workman's Compensation Act, 1906, work in practice, and whether the medical referee is going to be the arbiter as to a workman's destiny that our reading of the Act and rules make him. No doubt judges will not like to give up any of the authority they already possess, and some of them certainly will not do so without a struggle. A few days ago a case under the old Act came before Judge Shand sitting in the St. Helens County Court, in which the medical referee's report was not acted upon through the most extraordinary legal quibbles it is possible to conceive. The case was one of a collier who met with an accident to his knee in the course of employment last December, and who was receiving ten shillings a week as compensation from his employers, and six shillings and sevenpence a week from the Miners' Permanent Relief Society. In March, the man went to several doctors, who told him that his leg was well and that he was fit to return to work, but he was not satisfied, and was finally sent to the medical referee for the district, who certified him fit to return to work. However, later there was some further trouble, necessitating an operation on the leg, and the man sued the company for compensation. It was argued at this case that the medical referee's certificate was of no avail because he had not disclosed to the workman a statement at the time of examination that he was acting as referee, and also because the plaintiff went to him on the advice of a miner's agent. After much argument the judge decided that the referee's certificate was not conclusive evidence of the man's condition at the time of the accident, on the latter ground, and entered judgment for the workman. To the lay mind it seems the height of fatuity that a medical man's certificate is not evidence of a patient's health because one man and not another advised the patient to consult him, and still more that such a certificate should be capable of being over-ridden by a Court.

Leadless Glaze.

The desirability of the introduction of leadless glaze in the interests of the workpeople engaged in the pottery manufacture is obvious. From the humane point of view it is imperative, and hardly less so from the point of view of the social and political economist. As an industrial measure to prevent lead poisoning by eliminating the lead is simply an ideal step, embodying, as it does, the golden maxim that prevention is better than cure. On the other hand, it is only fair to hear what the manufacturers have to say upon the subject.

Recently one of them, writing to a London newspaper, stated that the leadless glaze involved a loss of 25 per cent. of the total output as against 5 per cent loss when lead was used. In reply, it may be urged that whereas the State has nothing to do with the cost to manufacturers and consumers, its plain duty is to protect the lives of the workpeople. The writer quoted went on to say that lead might be used safely if only employers, foremen, and workmen would work together and carry out rules. Experience shows that that kind of combination invariably fails in practice. The writer winds up by remarking that "there is a greater remedy." After stating that most male "dippers" have a female attendant working with them, and that marriage follows in many cases, he remarks: "The offspring are pre-eminently unfitted to follow their parents' occupation, and should not be permitted to do so." The candid employer has surely given his case away in the last sentence. To what other cause than lead could the degenerate offspring be ascribed?

Motoring and the Opsonic Index.

The open-air treatment of consumption stands out as one of the great therapeutic facts of the last century; but it may be doubted whether we have yet learned how to avail ourselves of its benefit to the fullest extent. At present it might be imagined that motoring would act as a sort of extension of that method available, at any rate, in the less advanced stages of pulmonary phthisis. Possibly the advantages thereby gained would be more than counterbalanced by the dust that is inseparable from that mode of transit. Medical science has now turned its searchlight upon the question of the effect of motoring upon tuberculosis, and has at once secured a striking and important observation. Specimens of blood were taken from Mr. S. F. Edge, both before and after his recent famous drive of twenty-four hours on a Napier motor. The first specimen was found to have a tuberculo-opsonic index of 0.85, while the second, taken directly after the race, gave 1.17. The fact that the active resistance of the body towards the tubercle bacillus was raised after so great a feat of endurance is not a little striking. The motorists may be pardoned if they plume themselves somewhat upon this scientific aspect of their fascinating pursuit. The remedy of a motor ride is more attractive than that of cod liver oil, even when presented in the form of a palatable emulsion.

PERSONAL.

Queen Alexandra, on the 24th instant, opened the new buildings of the Hostel of St. Luke, which have been built in Fitzroy Square, London, at a cost of £24,000 (including the site).

On the 23rd inst. H.R.H. the Prince of Wales accompanied by the Princess of Wales, opened the new out-patients' department at St. Bartholomew's Hospital, of which his Royal Highness is the president.

We are informed that Sir James Reid, Bart., M.D., G.C.V.O., K.C.B., has been appointed a director of the Clerical, Medical and General Life Assurance Society in the place of Sir John Williams, Bart., M.D., resigned.

Dr. Graham Steell, M.D. Edin., Fellow of the Royal College of Physicians, London, has been appointed Professor of Medicine by the Council of the University of Manchester.

The Nettleship Medal, founded in 1902, to commemorate the work of Edward Nettleship, and to encourage research in ophthalmology, was presented at the Annual General Meeting of the Ophthalmological Society to Mr. J. Herbert Parsons, for his monograph on the "Pathology of the Eye."

Professor Friedrich Muller has been awarded the Order of the Bavarian Crown in recognition of his professional eminence.

Dr. Thomas H. Bryce, has been awarded the Keith Prize of the Royal Society of Edinburgh for two papers on the Histology of the Blood of the Larvæ Lepidosiren Paradoxa.

M. Gilbert Ballet has been recommended for the Professorship of the History of Medicine and Surgery in the Faculty of Medicine of the University of Paris.

Deputy-Inspector-General Andrew Maclean, who is ninety-five years old is father of Kaid Sir Harry Maclean who is now in the hands of Raisuli, the brigand.

Mr. L. A. Dunn, M.S., F.R.C.S., Surgeon to Guy's Hospital, has been elected a member of the Court of Examiners of the Royal College of Surgeons of England.

Mr. A. Pearce Gould, M.S., F.R.C.S., Surgeon to the Middlesex Hospital, and Mr. W. B. Paterson, F.R.C.S., Dental Surgeon to St. Bartholomew's Hospital, have been re-elected to the Board of Examiners in Dental Surgery in the same institution.

The estate of the late Sir W. H. Broadbent, Bart., Physician-in-Ordinary to the King, who died on July 10th last, aged seventy years, has been valued at £86,209.

Dr. D. S. Lazarus Barlow has been appointed Croonian Lecturer for 1909.

Major C. E. P. Fowler, Assistant Professor of Hygiene at the Royal Army Medical College, has been appointed for special duty at Gibraltar.

Dr. Julius Dreschfield, M.D., of 3 St. Peter's Square, Manchester, whose death took place on June 13th, bequeathed everything he might die possessed of in trust for his children. The value of the property is sworn at £71,016 15s. 10d. gross, and £68,914 12s. 11d. net.

Dr. P. H. Pye-Smith will deliver the FitzPatrick lecture of the Royal College of Physicians of London this year.

Dr. Frederick Taylor has been appointed Harveian Orator by the same college.

The following gentlemen have been appointed to the other official lectureships as follows:—

To deliver the Milroy Lectures—Dr. J. W. H. Eyre.
To deliver the Croonian Lectures—Dr. A. E. Garrod.
To deliver the Goulstonian Lectures—Dr. H. S. French.
To deliver the Lumleian Lectures—Sir James Sawyer.
To deliver the Horace Dobell Lectures—Dr. L. S. Dudgeon.
To deliver the Oliver-Sharpey Lecture—Professor Schafer, F.R.S.

A CLINICAL LECTURE

ON

THE VALUE AND FATE OF BELATED OVARIES. (a)

By J. BLAND-SUTTON, F.R.C.S.,

Surgeon to the Middlesex Hospital, and Senior Surgeon to the Chelsea Hospital for Women.

The ovary is essentially an egg-producing organ, and from this aspect alone it may be described as a temporary and ductless gland, its period of activity being coincident with menstrual life, with an average period of thirty years. The structural changes in the ovary according to its age support the view that it should be classed with temporary secreting glands, for, after the age of forty it diminishes in size and after the forty-fifth year the ova and follicles begin to disappear; at fifty, when the menopause is usually established, the ovary may weigh about one-sixth of its weight at puberty, and consist merely of fibrous tissue traversed by a few blood vessels with thickened (sclerosed) walls. Careful observations have shown that complete removal of both ovaries is followed by sterility, arrest of menstruation (amenorrhœa), and in young women, by an alteration in the general metabolism of the body which is manifested mainly by the curious vaso-motor phenomenon known to women as "flushings." Observations on the effects of removing the thyroid have shown that this gland though ductless, supplies a secretion which finds its way into the circulating blood and exercises a great influence on general metabolism, especially in young and growing individuals; this has led many to believe in the production of an internal secretion by the ovary but no one has succeeded in isolating such a secretion, and its existence is hypothetical. One observer (Heape) has suggested the name "gonadin" for this secretion, but it is rather like fixing the name for a baby before it is born. There is, however, ample evidence to support the view that the ovary performs other functions in addition to ovulation, and that these, like some possessed by the thyroid and adrenal, are exercised to their fullest extent in early life, especially during the growth and development of the sexual organs. In regard to this matter it will not be out of place to mention the interesting observations published by Bullock, Sequeira, Adams, and others, concerning children who have exhibited precocious development of the sexual organs in association with the growth of tumours in the adrenals (suprarenal capsules). In some of these boys and girls, the secondary sexual characters, such as the growth of coarse hair on lips and chin, in the axilla, and about the pubes, have occurred at the age of ten and twelve years. In some of them the changes have taken place so quickly that in the course of a few months a boy or a girl has become transformed into a sturdy little man or woman, as the case may be.

It has long been known that in adults with tumours in the adrenals, pigmentation of the skin, different from that seen in Addison's disease, has been accompanied by an abnormal growth of hair on the skin generally; in at least one case the abnormal hairiness disappeared after the removal of the adrenal tumour. This association of precocious development of the sexual organs with some disorders of the adrenal is of interest in connection with the investigations which Heape made on the cause of rut in mammals, including monkeys, and which led him to express the opinion that the ovary is not the seat of the governing power of the breeding function. This view has not met with any support, and lately the observations of certain German workers, notably Fränkel, tend to invest the ovary with more extensive functions than physiologists have hitherto assigned to it, for the peculiar yellow body (corpus luteum) left in the ovary after the rupture of a ripe follicle, and which becomes such a conspicuous object on the cut surface of the ripe ovary when pregnancy occurs, is now considered to play an important part by means of an internal secretion it is supposed to furnish which assists the embedding of the oösperm (fertilised ovum) in the tubal or uterine mucous membrane. This secretion, Fränkel believes, is elaborated by the lutein cells which are derived from the follicular epithelium.

The result of modern research tends to exalt the importance of the ovary and indicates that its ovigenous function is by no means the only duty it performs. Precisely what these accessory functions are, and what the essence is in virtue of which they are exercised, nothing is known, but I am able to assert that a very small portion of an ovary is sufficient for their maintenance. The most obvious function associated with the ovaries is menstruation, and although the cause of this unpleasant phenomenon is obscure we know that the complete removal of both ovaries completely arrests it, and the congenital absence of both ovaries is always accompanied by amenorrhœa. An ovary in a well-developed healthy woman may weigh upwards of 100 grains; nevertheless, the presence of 15 grains of ovarian tissue containing follicles is sufficient to maintain menstruation and prevent the occurrence of flushings so characteristic of the natural, as well as the artificial menopause.

I will give briefly the details of two observations which illustrate this matter:—Some years ago, a single woman, æt. about 30, suffered severely from painful menstruation, and at her earnest entreaty her medical attendant performed what he believed to be a complete bilateral oöphorectomy. His chagrin was great, but the patient's disappointment was greater when she found during convalescence that her menstruation continued as regular and the pain as bad as before the operation. Many months later the patient sought my opinion, and I explained to her the difficulty of complete ablation of the ovaries and that there could be little doubt that a portion of at least one ovary had been left behind. For a long time I refused to interfere with the case, but at length, at the request of some of her friends, I re-opened the abdomen two years after the primary operation and found a portion of the ovary and the corresponding stump of the Fallopian tube with the ligature attached to the uterine cornu. That this piece of ovary was capable of fulfilling its function was proved by finding in it a recent corpus luteum a ripe follicle, and, on microscopic examination, ova in its tissues. The remnants of the ovary and tubes were carefully ex-sected from the uterus, menstruation ceased permanently, and in the course of convalescence flushings began to annoy the patient.

(a) A Clinical Lecture delivered at the Middlesex Hospital.

This is by no means an isolated case. On another occasion in which bilateral oöphorectomy had been performed by a gynæcologist for the relief of dysmenorrhœa, the operation produced no abatement of menstruation and apparently aggravated the pain. A year later I operated upon the patient and found active pieces of ovarian tissue on each stump, and to ensure complete removal of the ovarian tissue I removed the uterus.

For many years I have insisted that the complete ablation of ovarian tissue, except when the pedicles of the ovaries are elongated by the dragging of a tumour, is by no means an easy matter. On the other hand, when the uterus is occupied by a fibroid, the ovarian ligament is sometimes so short that the one or other ovary appears to be almost sessile on the uterus; in such conditions the complete removal of the ovary is an impossibility. I am able to demonstrate this by an actual specimen:—

A single woman, when æt. 28, had both ovaries removed at the Samaritan Hospital, London, for the relief of profuse menstruation due to a uterine fibroid. The operation did not arrest menstruation, but made it irregular and it remained profuse. Seven years later it completely ceased and remained in abeyance two years; then the flow reappeared and the patient noticed a swelling in the hypogastrium which increased in size, was painful, and interfered with micturition. In April, 1906, I performed hysterectomy, and found the uterus occupied by an interstitial fibroid which had undergone red degeneration (aseptic necrobiosis). On the right corner of the uterus there was a piece of ovary the size of a large ripe white currant. I have always maintained that it was an excellent effort of reasoning which led Lawson Tait in 1872 to the deduction that as uterine fibroids usually cease to grow after the natural cessation of menstruation, it would be useful to induce an artificial menopause in women with troublesome fibroids by removing their ovaries. He not only conceived the idea, but possessed the ability necessary to carry out the operation and convince the whole surgical world of the soundness and utility of the proceeding. In the quarter of a century succeeding Tait's brilliant observation, the surgery of the female pelvic organs had been brought to a high state of perfection, and hysterectomy can now be performed with less risk than bilateral oöphorectomy. This induced me to reverse Tait's operation by removing the uterus and leaving the patient at least one ovary. The reasons were practical enough, because as I have already mentioned, it is difficult to remove completely all the ovarian tissue and leave the uterus; the relief is neither prompt nor certain; convalescence is slow and often tedious, and with all these inconveniences and uncertainty there was a great disadvantage to the patient if the ovarian tissue was completely excised, for she would have the annoying signs of an artificial menopause.

These opinions were advocated at a meeting of the London Obstetrical Society in 1897, and led to much opposition, but they quickly gained support, and the speaker in the discussion who treated the idea of the conservation of the ovaries with derision, within a year became one of its most ardent advocates. To-day I am justified in stating that every surgeon who performs hysterectomy for the treatment of uterine fibroids always seriously considers the conservation of at least one ovary in women æt. under 40 a matter of prime importance, and some believe in the value of preserving an ovary even at any age.

It is now admitted by surgeons who have had much experience of hysterectomy for fibroids that the immediate results of preserving at least one ovary in this operation are admirable; but I have already pointed out elsewhere that the expected benefits have been over-estimated, and the preservation of ovarian tissue is of value within certain limits. In 1901, Dr. Crewdson Thomas obtained the after-history of 100 patients who had been submitted to hysterectomy for fibroids, and he came to the conclusion that subtotal hysterectomy does not interfere with the sexual passion and that the retention of an ovary is of striking value "in warding off the severity of an artificial menopause," more especially when the patient is æt. below 40; above that age the ovaries decrease in value every year. This enquiry interested me very greatly because many of the patients included in this investigation had been under my own care, and I was so satisfied with the deductions that it became with me a working rule to take unusual pains to preserve at least one ovary in women æt. under 40, but in patients above that age I do not hesitate to remove both ovaries and Fallopian tubes if the removal facilitates the operation, or if these structures do not appear satisfactory and seem in any way likely to give subsequent trouble, because it must be borne in mind that the retention of one or both ovaries is not free from risk. My practice in this matter rests on the following basis: When both ovaries are diseased, I remove them, taking care to distinguish between an œdematous and a diseased ovary. The annoyance caused by flushings is slight compared with the dangers caused by suppuration in a Fallopian tube or in an ovary. I have had an example of each in my own practice, and the facts of each case may be briefly given.

In March, 1898, I performed subtotal hysterectomy on a spinster, æt. 50, on account of a very large interstitial fibroid which caused her to lead a semi-invalid life. Both ovaries and tubes were left and for some weeks after the operation the stump which suppurated gave some trouble and the right Fallopian tube became a pyosalpynx. This I removed in November, 1900. The ovary was large and œdematous, and on microscopic examination seemed to be made up of inflammatory tissue. I found no traces of either ova or follicles. The patient is in excellent health at this date, July, 1906.

The second case is very instructive. In 1906, I removed the uterus from a married lady on account of fibroids which had caused the uterus to become impacted; great pains were taken to preserve both ovaries and tubes. At the time of the operation they were normal in size and shape. The patient did not recover from the operation in the usual satisfactory manner. There was pelvic pain, particularly on the right side, accompanied by a slowly progressive rise of temperature. After six weeks spent in vain temporising, it became necessary to reopen the abdomen, when to my great surprise I extracted an ovary the size of a tennis ball, which had become converted into a sac filled with blue pus, which proved to be sterile in the laboratory. The Fallopian tube had undergone no change. The patient made a tedious but satisfactory recovery.

It must be borne in mind that belated ovaries may become the source of tumours, as in the case of ovaries which have remained in union with a normal uterus; of this condition I have only had one example. I performed vaginal hysterectomy on a single lady, æt. 36, for carcinoma of the body of the uterus; both ovaries and Fallopian tubes were left. She remained in excellent health five years, then a tumour the size of a fist formed in the left half of the pelvis. Cœliotomy was performed and the left ovary was converted into a tumour displaying the microscopic characters of the growth for which hysterectomy had been performed. It was easily removed. The right ovary had atrophied and was represented by a small body the size of a holly berry; the corresponding Fallopian tube appeared as a thin cord attached to it. The patient reported herself in good health three years later. I am unaware of any observations relating to cysts or tumours arising in ovaries which have been left after hysterectomy for fibroids.

Although I have left one or both ovaries in the performance of hysterectomy for fibroids in more than 300 patients, since I advocated the practice in 1897 (see *Trans. Obstet. Society, London*, for 1897), in only two instances have I found anything detrimental in the practice. The last case, however, has led me to consider carefully whether it may not be more judicious to leave only one ovary, and since the beginning of 1906, I have systematically removed one ovary, and find that the immediate good consequences of the operation are in no sense impaired; and in some of the patients I have for greater safety removed the corresponding Fallopian tube.

Those surgeons who have critically studied the conditions of women after hysterectomy are unanimous in the opinion that it is a great advantage to the patient, to say nothing of comfort, to preserve at least one ovary; and I think there is also substantial agreement that whatever good effects follow the practice of leaving ovaries divorced from the uterus in the pelvis they are only temporary, for in the course of a few years the ovarian tissue disappears, and the patients experience the usual symptoms of the menopause like their healthy sisters. I think it possible that the rate of atrophy of the secreting tissue of a belated ovary largely depends on the age at which the patient is submitted to hysterectomy.

My opportunities of learning the fate of such ovaries have happened when patients who have been submitted to hysterectomy have required a second operation for such troubles as appendicitis, or gall-stones, then on the performance of these operations I have taken especial pains to examine the ovaries. On three occasions on which I examined the condition of ovaries conserved in the course of hysterectomy, two three, and five years after the operation, they had shrunk to small nodules about the size of cherry stones, but all these patients had passed their fortieth year at the time the uterus was removed. In April 1899, I removed the uterus and left ovary from a single woman, æt. 29, on account of a growing fibroid. In February, 1905, she again came under my care, and was operated upon for appendicitis. The belated right ovary occupied its normal position at the brim of the pelvis, appearing normal in size and function, for it contained a ripe corpus luteum.

Some writers, particularly Doran, refer to the occurrence of menstruation after subtotal hysterectomy with conservation of one or both ovaries, and in the performance of the operation he has carried out a method (Abel-Zweifel) by which a small segment of the menstrual area of the uterus is left which permits menstruation to be continued in a subdued form. Doran's paper, in the *Trans. Obstet. Society*, 1905, Vol. XLVII., p. 363, is worth perusal, but I cannot express any opinion as to its value as I have never had the courage to try it. My aim in performing hysterectomy for fibroids is to abolish as completely as possible the menstrual area of the uterus, and up to the present my efforts have been successful, and I have no complaint from any patient that this disagreeable phenomenon has manifested itself, although I have been at great pains by my own exertions as well as by the kind efforts of those who have been associated with me in my hospital work to keep in touch with women who have been so unlucky as to require such a serious operation as the removal of the uterus.

The experience which I have gathered as the result of studying the after-effects of hysterectomy in the treatment of uterine fibroids teaches me that in the performance of the operation there are three very important points requiring consideration in women æt. under 40, apart from the main inconveniences which render the operation a necessity, such as hæmorrhage, impaction, sepsis, interference with pregnancy, obstruction to delivery, &c. These three points relate to (*a*) the patient's comfort in securing freedom from flushings; (*b*) if she be married her marital relations; and (*c*) if single, her nubility. These three conditions depend mainly on the conservation of a healthy ovary.

In regard to marital relations, nothing trustworthy is forthcoming, but I believe the retention of an ovary is an additional factor in promoting domestic bliss, and many husbands in giving consent to hysterectomy are particular to insist that some amount of ovarian tissue shall be conserved if possible. The question of nubility is an interesting one. I am able to state that single women who have had subtotal hysterectomy performed with conservation of an ovary have married and lived happily with their husbands, and I am of opinion that the preservation of the vaginal segment of the neck of the uterus is an important factor, as it leaves the vagina intact, and though such women are sterile they are certainly nubile.

I have endeavoured without overstating the case to show that a belated ovary is of high value to a woman æt. under 40, whether she be married or single. In regard to the fate of such ovaries, I think in the present state of knowledge it may be expressed in this way:—In women æt. under 40, a belated ovary remains active and discharges ova.

An ovary belated after the fortieth year rapidly atrophies and menopause symptoms may ensue in the course of a few months after the operation. The retention of the ovary minimises the menopause disturbances, and they are never so acute and prominent under these conditions as they are when an acute menopause is induced artificially.

Up to this point the observations which I have ventured to relate are based mainly on clinical experience, and it is a matter of interest for me to find that they have received experimental confirmation of a remarkable kind. Mr. Bond has published a series of experiments on rabbits performed for the purpose of clearing up some doubtful points in uterine and ovarian physiology (*British Medical Journal*, 1906, 1, p. 121). Among these experiments some bear directly on the subject of this lecture, especially those performed with the object of investigating the effect of removal of the whole uterus on ovarian growth and function. The experimental removal of the whole uterus has no deterrent effect on ovulation, and it does not prevent the occurrence of œstrus and ovulation at periodical recurring intervals.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by R. H. Woods, M.D., F.R.C.S.I., Throat Surgeon to Sir Patrick Dun's Hospital. Subject: "The Treatment of Suppurative Otitis."*

ORIGINAL PAPERS.

ABSTRACT OF THE PRESIDENT'S ADDRESS

Delivered July 30th, at Exeter,

AT THE

ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

By HENRY DAVY, M.D., F.R.C.P.

Physician Royal Devon and Exeter Hospital.

SCIENCE IN ITS APPLICATION TO NATIONAL HEALTH.

THE most important function of the medical profession is the practical application of the science of their day to the health and life of the individual, and through him to the community, and our success and usefulness depends on the truth and the value of the knowledge which the science of the day has reached. In earlier times there was very little in the knowledge of the day of which medical men could avail themselves usefully to explain or to combat disease, and the place of true scientific knowledge was occupied by more or less inaccurate theories as to the causes and best way of treatment of various diseases; such theories, for instance, as those of Brown and Rasori, which held that all disease was due to too much or too little stimulation and which lead to bleeding and the abuse of stimulants, in the treatment of disease, that may be observed right down to the time of our last meeting in Exeter. Theories which, as the late Dr. Moxon once said, "were then thought to be the pride of medicine, but which we now consider as at any rate the curse of the patients who were hurried into the next world with the lancet or the brandy bottle on rational principles."

In considering the changes which have taken place in medical knowledge and treatment during these sixty-five years, we have to remember that the knowledge which we use in the profession of medicine is of two kinds—empirical and scientific, using these terms in their highest sense. Each of these systems is of great importance. Much of the best information about disease and many of the most useful plans for its treatment have been handed down to us from remote ages as the product of experience and observation, and are thus truly "empirical," and a large part of the empirical observation of the early Forties is as good to-day as it was then. The knowledge which we call scientific—that gained by systematic experiment and reasoning—is of even more importance; in fact, when founded upon proved truth, it is all-important, and it is the possession of such accurate and true knowledge that distinguishes the medicine of to-day from the medicine of the early Forties.

Much of this accuracy is due to the perfection of the microscope and to the development of organic chemistry, which have enabled us to gain a more or less complete knowledge of the organs of the body and to understand the chemical changes which are constantly taking place in them, both in health and in disease; while it has in some cases also revealed to us the actual germs to which many diseases are due, and the actual toxins which these germs form in the body. These discoveries have entirely reconstructed our knowledge of the various organs of the human body and of their functions, and in the same way they have revolutionised our theories of diseases, of their causes and modes of onset, so that, for the first time in the history of medicine, we are possessed of scientific facts on which to base both theories and practice. And what a gain is this for the profession of medicine in its relation to the public!

We have reached a position with splendid opportunities for usefulness, and a position which will have to be much more definitely recognised by the nation at large if all its advantages are to be fully utilised. It is a position which also carries with it great responsibilities, and we must be careful how we use it. Let us be careful that we teach only what we know to be the truth, avoiding the "premature generalisation" and "rational theories" of the ancients, using both our empirical and our scientific knowledge when necessary, but not attempting to force the acceptance of anything unless it can be demonstrably proved to be true.

The ancient Greeks showed a true appreciation of health when they gave divine honours to Aesculapius, the first physician of the Argonauts, and to his daughter, Hygeia, the Goddess of Health. It would be well if in these days people could be made to understand thoroughly that the cultivation of health is the first necessity of useful lives, and, if they strove to attain it, as the first object of their solicitude; if they recollected that the chief and best asset of a nation is the number of healthy individuals it contains; and if they would also recognise the great principle that no educational system is good which does not aim at producing well-developed, healthy bodies as well as well-trained minds.

Now, in considering all questions of health we have to consider not only the individual patient, but also his environment; meaning by this the sum total of influences which modify and determine the development of his life and character. This question of "environment" has of late years come very much to the front with regard to the question of physical deterioration of the nation as illustrated by the number of would-be recruits for the army who are found to be so physically undeveloped that they do not come up to the requisite standard. It has been carefully and ably dealt with in the report of the Inter-departmental Committee of Physical Degeneration of 1904, a report which ought to be studied by every one who has the health and welfare of the nation at heart.

Time will not allow me to deal very fully with the subject, but I would ask your attention to one or two points, marking them carefully, because they so fully illustrate the scientific teaching which we have gained during the last sixty-five years.

History repeats itself; the first physicians appointed by the authorities of the ancient Greek towns were trained gymnasts from more or less celebrated gymnasia, who treated their patients with regulated diet and regular exercise; and if the English in the twentieth century are to keep themselves free from physical deterioration, our profession must put themselves in the van of a similar movement and show how necessary physical culture and muscular activity are to a nation of "muscular degenerates."

Physical culture is, in my opinion, one of the most pressing questions of the day, for it is by it alone that we have a proper remedy for the state of muscular degeneration which is so prevalent. It ought to be considered by every educational authority, for by its use dwellers in city and country alike can have their muscular systems built up and developed to a healthy standard. There is no need that any collection of children who are not diseased should become a class of muscular degenerates.

For the children of to-day are the men and women who compose the nation of to-morrow, and if they are diseased and physically deteriorated, the nation in the near future will be equally effected. Is it sufficiently recognised how greatly the future of the nation is decided during the school life of its children? It is while the children are at school that you must give them the foundations on which the whole of their future, physical, intellectual, and moral, is to be reared, and if they are not shown how to develop their bodies and keep them in health, the only chance of their learning it has been missed. It is also essential to see that during their school life they are not exposed to contamination from disease, and this can only be done by placing them under the supervision of a trained and qualified medical man, as is done in Japan and in nearly every other country in Europe except England. As the Committee of Physical Deterioration emphatically recommends, every school in the country without exception should be under the supervision of a properly trained medical officer. It should be his duty, with his assistants, to examine every pupil to see who are healthy and who are diseased, who are fit for a course of physical culture and who are not, and generally to look after the health and development of the children. How necessary such medical supervision must be is proved by the fact that Dr. Alfred Greenwood, Medical Officer of Health for Blackburn, in an examination of 388 school children of that town, found that no less than 54 children were affected with some form of tuberculosis, and of this number 34 had tuberculosis of one or both lungs.

I would recommend to the notice of all educational authorities the example of Rugby School and of the scheme originated there by Dr. Dukes, one of the best-recognised authorities on the health of public schools. There every new boy undergoes a carefully-recorded and rather full physical examination, and the games and exercises that he "may play" and "ought to be made to play" are also recorded. But we must go further than this system of games. I quite agree that every boy in every school ought to have a course of physical exercises prescribed for him, adapted to his particular need, and that he should not be allowed to play any game unless he has attained a certain level of muscular development; then we should have a very different condition of affairs from that just revealed. In a public school it would be a point of honour to reach the necessary degree of muscular development to play games, and in the elementary schools the physical exercise would itself develop the muscular tone which is wanted. I would urge on the educational authorities that they are responsible for the development of the pupils' bodies as well as their minds, and that it is of little use to the nation to bring up men with their minds stored with facts but their bodies left ill-developed and generally degenerate.

Next to this question of physical culture, and of equal importance, is the question of the feeding of the people, and it is one of the problems on which we, as teachers of the science of our day, ought to have much to say. "Food," says Dr. Eichholz in his evidence before the Committee, "is the point about which turns the whole problem of degeneracy;" and no one who reads the Report of the Committee on Physical Degeneracy can doubt that the ignorance of people in relation to this matter is truly lamentable. Now, during the last sixty-five years we have gained an immense amount of accurate knowledge with regard to food. We have accurately determined the elements of food and the kind of work which each performs in the system; we know the actual processes by which they are digested, and the part which the various organs take in each process; we have determined the metabolisms they undergo and the excretory products which they form, and how, and by what channels, these products are eliminated. We can estimate the amount of each element required to keep a person in health, and understand the diseased states which are produced by the consumption of too much or too little of the various elements. But, although we have learnt so much about food, I do not think that we have ever yet succeeded in teaching this knowledge in a practical and useful way to the world at large.

We want then, as a profession, to set out clearly, plainly, and shortly the scientific knowledge we have gained, as regards food, in a really practical way that can be understood by the multitude and can be applied to their everyday life; and until this is done I do not see how we can deal with the popular ignorance which prevails on the subject.

It is a sad reflection that we are obliged to appoint a committee to inquire into the physical deterioration of our people when we possess enough knowledge to maintain a very high standard of health if only this knowledge was utilised; and I am glad that this Association is pressing this point on the attention of the Government, and that the views of the deputation which it recently sent seem to have been more or less accepted by the educational authorities.

We shall never be able to deal satisfactorily with physical degeneracy and the prevention of disease so long as the majority of the men and women in the nation remain in absolute ignorance of the very rudiments of science and hygiene. It is not creditable to our educational systems that a so-called "well-educated" gentleman, who may one day be called on to legislate for his country in Parliament, should be able to go through one of our best public schools, and take a degree at one of our oldest universities, without the least knowledge of the composition of the atmosphere, and without the most elementary ideas as to food and hygiene; but so it is, and I despair of improving the health of this country, and of preventing a mass of preventable disease, so long as this anomalous condition of education exists. For in the prevention of disease we as a profession can do little or nothing unless we have the support of public opinion behind us to assist in carrying out the precautions which science shows to be necessary. It is, I think, greatly to our credit that we have accomplished as much as we have in diminishing disease under the present condition of affairs; that we can do little or no more until public opinion is aroused in the matter I will illustrate by asking you to consider the history of pyæmia, typhoid, and tuberculosis. These three diseases have been proved to be caused by the development of certain microparasites which have all been discovered within the last thirty years. Pyæmia and typhoid are, as you know, in the category of diseases which come under the supervision of the Act which deals with infectious diseases, while tuberculosis is not; so that in the latter case we have no means of enforcing the precautions which we know to be necessary.

Now, in the case of pyæmia, the magnificent work done by Lord Lister has shown the world not only the cause of this disease, but the actual precautions by which it may be prevented, the use of these precautions depending on the surgeon and his assistants and on no one else. And so well are these precautions carried out that pyæmia has become almost extinct within these past ten years throughout the civilised world, with a saving of life and misery which cannot be calculated.

Typhoid is also becoming more and more infrequent, and this is generally credited entirely to the improved sanitation and better water supply of the country. But I think these are by no means the chief factors in the case, for there are plenty of insanitary houses still remaining in England and the water supply is too open to the gravest suspicion.

The decline of typhoid fever is largely due to the fact that medical men have done much to destroy it. Its bacilli nowadays are never allowed a chance, at any rate in this country. In every case of the slightest doubt, days before there is any possibility of making a certain diagnosis of typhoid, it is the invariable practice to thoroughly disinfect the patient's stools; and it is to this constant and systematic destruction of its bacteria by disinfectants that, I believe, the diminution of typhoid is chiefly due; and that if these measures of disinfection are continually carried out, this disease will in a few years be as rare as its kindred disease, pyæmia.

Far different is the history when we come to examine tuberculosis, the exact nature of which as an infectious parasitic disease was discovered by Koch twenty-five years ago.

Consumption is an infectious disease in precisely the same manner as is typhoid. In the one you have the bacilli of infection in the sputum, and in the other in the motions, and unless you disinfect them both the infection becomes generally distributed.

Now compare the history of tuberculosis with those of typhoid and pyæmia. I am quite aware that it has decreased under the influence of improved sanitation during the past few years, but yet its prevalence is even now appalling. Approximately, its death-roll in Great Britain is 60,000 persons a year; and Dr. R. W. Philip, of Edinburgh, has shown "that the ascertained mortality from consumption may be safely multiplied by ten in order to represent approximately the number of persons living and already seriously affected at the time, so that Great Britain at the present moment contains 600,000 poor patients with a preventable infectious disease, the large majority of whom are bound slowly to die of an illness which will linger on for from two to five years.

I think it is time that we spoke out the truth about this disease with no uncertain voice; for surely it is time that something was done officially in this matter, and that the attempt to stay the ravages of this terrible disease be no longer left to voluntary associations who must of necessity be unable satisfactorily to deal with a task of such magnitude. Are we to admit that tuberculosis alone amongst the infectious diseases is to have no precautions insisted on with regard to disinfection? Are we for ever to allow consumptives to disseminate their infectious sputum in the streets of our towns; or are we to allow them alone of infectious patients to stay in any hotel or lodging in England without taking any precautions? Nearly every nation in Europe, except England, has awakened to the need of dealing with this disease on scientific lines, and it is time that we followed their example.

I am quite aware of the difficulties which surround the whole question, and I do not wish to put forward my own views as to the measures which are practicable in dealing with the disease. All one-sided statements only tend to obscure the issues and increase the difficulties of the situation. Satisfactory legislation can only be obtained by its careful consideration from many points of view; but is it not time for the the Government to make a careful inquiry into the subject, and that, having obtained the best expert and other opinion available, and having considered the precautions which other countries are taking, they should bring forward legislation to deal with this disease, which yearly destroys nearly 60,000 of our people and brings misfortune and sorrow into some 600,000 homes in our country.

In one of his most striking passages Rudyard Kipling says: "We are a great people and very strong, but we build our empire in a very wasteful way—on the bones of the dead who have died from disease!" It is for our profession, gentlemen, as the advisers of the nation on all matters of health, to show how much of this terrible waste can be prevented; and just in proportion as we succeed in doing this, in that proportion we shall be carrying out the highest purpose of our profession in maintaining the health of the individual and in preventing the degeneration of the nation.

HEADACHES AND THEIR CAUSES.

By Prof. FREDRICH PINELES, M.D.,

Vienna.

[Specially reported for this Journal.]

This is a vague subject, but a common complaint of every-day occurrence, and so complicated in its origin that a lecture devoted to the subject cannot fail to be useful and instructive. A pain in the abdomen, chest, or limbs may be located and relieved at once, but in the head it is more complex and uncertain, though the history may assist us in many cases to make a correct diagnosis. Our first suspicion will be directed toward a pathological change in the brain substance, its coverings, or communicating tracts, the latter having their distribution throughout the body and conveying impulses to the sensitive mass in the encephelon. The brain being the great centre of motion, for the whole body, will affect the whole organism when any morbid change takes place in that organ, and *vice versa*, any pathological change in a distant organ will be reflected on this sensitive centre and may exhibit changes from the long exposure to abnormal excessive stimuli. Headache from this varied origin must be carefully investigated, and every organ of the body minutely examined. The pain in the head may only be a symptom of the disease going on elsewhere, and immediately relieved when the disease is ameliorated or removed.

Among the principal causes of headaches are hyperæmia or anæmia of the brain substance; irritation of the dura mater; and toxines, which adversely influence the vaso-motor centres. Here are a few of the causes whose action we know little of, though vague theories are frequently proffered for acceptance and subsequently disproved by facts.

Let us begin with that form of headache associated with pathological changes in the cranium, including skin, muscle tendon, and periosteum, included under the more common terms of rheumatic, cicatricial, luetic, and nervous parasthesia.

The rheumatic arises in the muscles of the head, and is specially designated as myalgia capitis, and is further specialised as temporalis, frontalis, occipitalis, or galea aponeurotica, according to site. These are usually aggravated by chewing, moving the jaws or any of the facial muscles, as well as by pressure on any of the muscular groups. The pain may be unilateral or bilateral, but it rarely produces trismus which resembles tetanus in its appearance.

There is another form of cephalalgia indistinctly understood by us in Vienna, probably owing to its rarity, but well defined according to Edinger, of Frankfort, and Henschen. It commences with severe pain in the back of the head and down the neck extending to the shoulders, the incidence falling heaviest on females about middle-age and upwards. It is usually preceded by cold and shivering extending over a considerable period. The great peculiarity of this form of cephalalgia is the tubercles, or small nodules, that form in the cellular tissues on the posterior part of the head and down the neck ranging in size from peas to large beans. The nodules form lines across the posterior part of the head, down the neck, and around the mastoid, which have led to the name cicatricial, or band-like headache.

Another peculiar characteristic is the readiness with which this form of headache yields to massage. To show how rare this disease is in Vienna, not a single case has been seen in or out of the hospital during the last twelve months. At the present time it seems to be confined to the north of Germany, where it may be indigenous.

In the maculose, papulose, or later stage of syphilis periostitis is a frequent cause of headache, and as these inflammatory centers usually select the forehead and temporal region, they may be mistaken for other diseases than syphilis. This form of headache forms 28 per cent. of the total met with in Vienna, and should not be lost sight of in all our diagnoses with this as the prominent symptom. It is usually recognised by the patient's description of a tearing or boring pain, increased by pressure over the site, and is intermitting in character, with nocturnal exacerbations, commencing about midnight and lasting two hours very severe, gradually becoming less in the morning. This increase of pain is probably due to some change in the circulation. Immediately the periosteal deposit becomes absorbed, the pain subsides, and the patient is relieved.

The nervous parasthesia is a troublesome form of cephalalgia, affecting every hair follicle of the head, giving pain to the touch; it is usually ushered in by an itching sensation in the scalp, as if some noxious insect were present, while stroking the hair gives pain, though severe pressure gives relief. Closer investigation of these cases reveals some other nervous trouble, of which the headache is but a symptom, of the neurotic, neurasthenic, and the hysteric type; but we may also have the graver affection of hæmicrania and other organic affections of the brain substance. In the neurasthenic, the pain is complained of as a great pressure in the head, although it may be localised to the brow, the temples, or back of the eyes. There are such a variety of symptoms given that careful judgment is required to discern the real seat of lesion. Some will describe the pain as a plank in the forehead, others that a load of lead is bearing the head backwards; but most of them will call it a splitting or wrenching pain. A continuous localised pain usually gives the greatest concern as it reduces the strength and incapacitates the patient for any useful work.

The hysteric headache may last for weeks or months at a time, depriving the patient of sleep or rest, varying in intensity, and locating itself to the brow, parietal, temporal, and occipital regions, resembling in every particular the neurasthenic headache, but the latter is more frequent in the forehead, while the hysteric is usually confined to the parietal region. In the hysterical, the headache has its exacerbations in the parietal region, which is usually described as the clavus hystericus, limited to a narrow area and represented by the patient as a nail driven into the sagittal line of the head, though others may call it a boring or stabbing pain, but all localising it to the sagittal region. Touch or pressure over this area gives great pain, and the skin is usually very hyperæsthetic. This clavus is sometimes associated with general malaise, vomiting and dimness of vision, which may be mistaken for migraine. Another mistake that may arise is where the hysteric headache assumes the form of occipital neuralgia, which begins at the posterior part of the head and extends forward; but the hyperæsthesia or sense of touch may differentiate the two diseases. Again, the occipital headache may be associated with malaise, vomiting, stiffness in the neck and feebleness of the legs, which we recognise as hysteric pseudo-meningitis.

Migraine usually commences in the middle of a disease. It is more frequently unilateral and circumscribed, selecting the eyebrows, the back of the eyeballs, radiating to the upper jaw or settling down in the posterior part of the head and neck. The character of the pain is varied, having the feeling of being situated in the bone or located to the interior part of the brain, and radiating to the cranium, while others describe it as if tearing the head open. It usually lasts from twelve to twenty-four hours, but it sometimes extends over many days. One of its pathognomonic symptoms is the alternate rise and fall of the attack, the succeeding attack always appearing before the preceding one has disappeared, which produces the status hæmicranicus. It is usually hereditary, and attacks the young and may be assumed to depend upon some morbid condition of the central system. The diagnosis and prognosis of this disease is a difficult but important factor in the treatment, as tumours or other growths may be the remote cause of the pain. When a cerebral tumour is present, vomiting without relief and at very short intervals is usually present. The patient is apathetic though the sensorium may be normal and where tabes is present the progressive paralysis soon declares itself. Another differential diagnostic sign would be the hereditary family weakness commencing in young persons as idiopathic migraine, but subsequently diffusing itself as a general headache and yielding to syphilitic treatment. When individual symptoms of epilepsy and hæmicrania are present, it will be difficult to decide the origin. It is usual in these cases to observe the presence of cramp for deciding on epilepsy, which may be present in the tongue or some of the facial muscles.

The most important change in the central system, when there is a neoplasm is a constant headache. The great characteristic is the severe pain, which is intense and constant, causing the patient to despair of relief. The character of the pain in tumours of the brain is for the most part diffuse and not localised, although it is dangerous to lay this down as a rule as many of the tumours give rise to localised pain which moves from place to place and cannot properly be localised. When the pain is confined to the posterior part of the head and neck, it is possible to locate the growth to the cerebellum; where it radiates down the dorsal region to the arms, we may be able to diagnose the neoplasm to be located in the tentorium.

If the pain be located in the anterior part of the head the neoplasm may be suspected near that site, but this is always a very dangerous conclusion, as many of these tumours radiate widely and are far removed from the site of pain. For instance, any irritation in the dura mater may act on some of the branches of the trigeminus, which might be considered the vehicle of pain, and thus lead to a false diagnosis of the case.

Another common headache is associated with meningitis in all its different forms and degrees. In lepto-meningitis it is an early symptom, and appears with unerring constancy.

Syphilitic headache is the early stage of basilar meningitis. It commences with great severity with nocturnal exacerbations about the same hour every night, and passes off on the following morning at the same time as on the previous day. It is diffuse in character, but locates itself within the cranium. This form of headache commences early in the disease and may continue for months or years.

In contrast to syphilitic basilar meningitis comes the convex meningitis or the meningitis of the upper vault of the cerebrum. Here the pain is not so constant as in the basilar form, although it is more circumscribed both by pressure and percussion. The primary syphilitic arteritis is the probable cause of the pain, which is not so severe or protracted as the basilar form.

Cerebral abscesses cause the pain to be constant and well localised in one hemisphere or the other. If the abscess be due to otitis media, the pain will be located in the temporal or occipital region.

Besides these more important causes, there yet remain a few minor sources of headache, all more or less affecting the brain indirectly, and producing severe pain. Diseases of the nose and its proximate cavities, such as chronic rhinitis, adenoid vegetations, hypertrophy of the turbinate bones, septum deviation, polypi, fibroma, &c. The pains associated with these are varied and of different intensities, and are described as boring, stabbing, tearing, and crushing, appearing over any part of the cranium. The chronic form of any of these diseases may set up empyæma, with acute exacerbations, by checking secretions, producing congestion or preventing the easy flow of secretions along natural channels. Empyæma may be induced by over-exerting the corporal and psychical functions as well as the intemperate use of alcohol and tobacco, which must be carefully differentiated from the above for treatment.

Frontal sinus changes may produce intractable supra-orbital neuralgia, recurring daily at particular periods, but the character of the headache in these cases is so different that no clear description can be given. All are more or less diffuse and ill-defined about

the forehead, and may arise from the maxillary sinus, ethmoid or sphenoid cells as well as the frontal sinus. Morbid changes in these centres not infrequently cause pain in the occipital, parietal, and temporal regions, as well as in the forehead, and have no fixed character. Teeth, again, particularly carious teeth, cause pain in the temporal region, which disappears rapidly on extraction.

The anæmic headache is well known to every practitioner. The chlorotic girl, the parturient exhausted mother, the female suffering from some chronic genital trouble, or the over-worked student, accountant, and teacher, are well known examples of sufferers from this malady.

The toxic headaches form another extensive class. These are often divided into exogenic and endogenic, which is not a very scientific arrangement, as all exogens taken soon become endogens. The former comprehend alcohol, nicotine, mercury, &c., while the latter are well represented by the toxines of fevers, infections from abscesses, the abscess of lungs in tuberculosis, constipation, arterio-sclerosis, &c. These have no particular symptom or site that can distinguish them from any of the other causes; the general condition of the body must be the guide. There is one of these toxines, uræmia, that deserves special note in the diagnosis; it can be defined as a piercing, pressing pain in the forehead though sometimes met with in the occiput. It may be continuous for days or recur hourly for some time.

A pathognomonic symptom in uræmia is that the headache may continue days and weeks accompanied with sickness, and vomiting unconnected with error of diet, and defying every drug in the pharmacopœia

Headache from disturbance in the alimentary canal is often complex and difficult of solution from its close connection with errors in diet, nervous dyspepsia, or neurasthenia with atony of the digestive tract. We have already referred to people who suffer from severe headache, of which constipation alone is the cause, and when this is relieved the headache disappears. This is a plausible explanation, as the accumulation of fæces presses on the surrounding vessels and diaphragm, disturbing the vascular system and deranging the reflex action and this finally affects the cerebral circulation, and in consequence headache supervenes. There is another source of headache in the ptomains that are liberated in sulphurous media.

The arterio-sclerotic suffer from severe headache owing to the disturbance in the circulation as well as that toxic products are liberated and thrown into the circulation.

It may seem strange that the genital organs should produce headache, but gynæcologists record cases where a displaced uterus has kept up headache for months without relief till the displacement was corrected, when the headache was instantly cured.

The eyesight is a well-known cause of headache; even in children this complaint is not unknown, arising from some refractive anomaly, insufficiency of the internal muscles, or enfeebled accommodation. A holiday for such children promptly cures the headache, which is characteristic in this form.

Cephalæa adolescentium is common to both sexes about the sixteenth or eighteenth year, it is relieved at night, but recurs on waking, and locates itself to the forehead. The youth is dull, weak, and unable for duty without great effort. This is an obscure form, and attributed by many authors to the development of the generative organs; others, to masturbation or abuse. The lecturer related other cases coming under his personal notice where the father had been a "Potator," while the mother suffered from hæmicrania, which suggested to his mind a constitutional origin for the cephalalgia.

Vasomotor disturbance is another fruitful source of headache and generally due to a congested state of the vessels which may arise from a variety of functional disorders.

A general rule for the diagnosis of headache is to first examine the nose, ears, eyes, and urine, and, on nothing being found to explain the cause, the duration is the next point to investigate.

If the headache be of recent origin, it may confirm the suspicion of neurosis, affections of the nose, otitis media, meningitis, teeth, or uræmia. On the other hand, if the duration be long, covering four or eight weeks, constipation, lues cerebri, uræmia, arterio-sclerosis, periostitis, or tumour may be the cause.

The therapy of this diverse disease cannot be confined to any particular line, but must be directed towards removing the cause. In the neurotic the patient should be supplied on waking with a little milk, chocolate, or fruit; never leaving the bed in a fasting condition. Many of these patients require a little food every two or three hours, and when engaged in outdoor work should carry small biscuits or such-like for the occasion. Against the localised pain in the head, a 10 per cent. menthol ointment may relieve it if applied twice a day. Vibratory massage sometimes acts favourably, but cold douches increase the pain. When the pain in the head is diffuse, high elevations, rest from work, or the "Winter Kur" will be found most beneficial, especially in hysterical cases.

In severe migraine cases, the diet should be strictly vegetarian, and free from every form of alcohol. The bromides must be given freely, from 2 to 3 grammes, or 30 to 50 grs. a day for six or twelve months, with 5 or 10 mimims of an arsenical solution. In addition to this, many cases require a gramme of sodium salicylate or aspirin recently introduced. Some obtain good results from antipyrin (0.5 to 1.0 grm), phenacetin (0.5 grm), migrainin (1.1 grm), pyramidon (0.5 to 0.75 grm), caffein (0.2 to 0.4 grm), &c.; but the necessity of the case may require a variety in the protracted course. The adjuncts are quiet, thermaphor, warm foot-baths, and, only in very severe cases is morphia admissible. In the hemicrania permanens, residence at great altitudes gives most relief.

Headache in children improves with hygienic attention, never allowing them to go fasting to school. In many cases a good breakfast will dispel all headache, but hot schools or badly ventilated class-rooms, with imperfect, or too strong light, may be the sole cause of the trouble. The medicine should be bromide of potassium, arsenic, and bathing the body with water at summer heat.

It only remains to consider the cicatricial or glandular headache of which we have little experience in Vienna. Our nothern colleagues prescribe sudorifics, sodium salicylate, or aspirin, thermaphor and massage. For the adolescent form, arsenic, iron, country air, with a generous diet of milk or fruit. Those in whom syphilis is suspected mercury, iodides, &c. In uræmic cases, laxatives, sudorifics, and caffein subcutaneously are useful.

SUGGESTED IMPROVEMENTS IN THE NOTIFICATION OF DISEASES. (a)

By J. C. McWALTER, M.A., M.D., D.P.H., F.F.P. & S. (GLAS.)

Of the King's Inns, Barrister-at-Law.

MUNICIPALITIES are concerned with the interests of mankind in the mass, and not as individuals—with the series or class and not with the mere units. Obviously the good of citizens at large is of greater moment than the ease or the privacy of individuals, and no private person is entitled to any right or privilege which materially interferes with the interests of society.

Therefore the interests of society demand that public notice be taken of the diseases from which individuals suffer—not from mere caprice or curiosity, but in order that they may be stamped out—the private individual cannot be heard to say that his privacy is invaded, or his rights trampled on. No people were so conservative of their rights as the ancient Romans, and none were so little disposed to pander to the prejudices of others; but the maxim of their law still prevails that we may use our advantages only when they do not injure others.

(a) Paper read at the Congress of the Royal Institute of Public Health held at Douglas, July, 1907.

The law requires the medical practitioner, under pain of penalty, to apprise the Public Health Authorities when cases of certain contagious diseases come under his notice. This is an apparent invasion of the rights and privacies of his patient, and an apparent breach of the confidence placed in the physician. But public opinion has long since sanctioned it, and the most lordly person recognises that his convenience must make obeisance to the public good.

The question which now arises for consideration is whether the principle of notification of diseases should not be extended far beyond the few infectious diseases in respect of which notification prevails. Is it worth while having the vast machinery of notification only that we may hear of a few cases of typhoid or scarlatina or diphtheria? A tendency now prevails among medical officers of health to look on zymotic diseases as the only ones which they can be expected to check, and if they can point to a diminution in the death-rate from zymotic diseases, to claim that they have fulfilled their functions.

This is one of those fallacies which are the opprobrium of medicine; one of those half-truths which have led scientific men into absurdities which persons of ordinary common sense should except. There appears to be a painful absence of the logical mind amongst the faculty which leads them to advocate measures of which the consequences have not been calculated or the effects foreseen. Thus we have gone to expense and brought on odium by our efforts to have every case of scarlatina notified. We were then forced to hold that our duty was to prevent the spread of the contagion, and hence we removed the patient to a hospital built at great expense. One consequence of this is that patients who think their children have scarlatina carefully avoid calling in the doctor, and another consequence is that when the patients are brought together in hospital the gravest case infects the lightest and the mortality and sequelæ are far beyond those of cases treated at home; whilst the length of stay and the resultant expense have been so great on municipalities compared with the trifling benefits, that doctors have fallen into great disrepute. Further, the fact remains that scarlatina has become of so mild a type that the mortality of untreated cases is but slight. Quite different has been our action with regard to measles and whooping-cough. Many municipalities paid at one time for the notification of these diseases, but the expense became so great, and the impossibility of making hospital provision so obvious that few authorities made any attempt to treat them.

We have then, an elaborate system of notification of disease carried out on the theory that contagious diseases being preventible should be prevented and that the adequate means of prevention are isolation and disinfection. We have also the anomalous position that out of the small number of infectious diseases prevalent in Britain, those which are amongst the most contagious and the most fatal—whooping-cough and measles—are, in most cities, not notifiable, and even when notified no adequate attempt is made to segregate them. Of the remaining diseases notifiable as infectious, scarlatina, diphtheria, and enteric are so liable to be confounded with other diseases that many practitioners hesitate to diagnose a disease as scarlatina, typhoid, or diphtheria until it has become so unmistakable that much danger from contagion has already occurred. The recent outcry in the press about the figures so unwisely published by the London Metropolitan Asylums Board—where it was shown that some 20 per cent. of cases were inaccurately diagnosed—has made the public much more critical about practitioners generally, and much more prone to proceed to law if the practitioner does not exhibit more than human sagacity in foreseeing the development of a disease. It is also to be feared that a recent decision in the High Court of Ireland—where it was laid down that the skill and care which the practitioner should exhibit must extend to the foreseeing of and the foreguarding against the unexpected results of his treatment—might induce a judge to hold with a litigant who contended that the fact of a doctor having made a mistaken diagnosis of a disease was *prima facie* evidence of negligence which the practitioner must suffer for unless he can completely misprove.

It becomes, then, under modern conditions, a very grave matter for the physician to diagnose a case as one of notifiable infectious disease. The patient and his household have a relation to society which is immediately altered in a very unpleasant fashion by the diagnosis. If it be a child at school, it must be kept away for several weeks, the other children in the house must be kept away, and the school authorities are indignant at the implied slight on the school. If it be a man or woman in a factory or large business place they, with those in the house, will scarcely be permitted to attend work. A species of interdict is placed over the place, and everyone's hand is against the unfortunate doctor who gave the notice. Afterwards the sanitary authority comes to disinfect—often with little tact—and if it be a public shop or other place of resort, it may be ruined by the suspicion of sickness. We have all had experience of this, and all this disturbance of society is due to the expression of opinion of a medical man who himself knows that the evidence on which he bases his view is far from being conclusive

Thus a practitioner is put in peril of a lawsuit every time that he reports a case, and every time that he neglects to do so he is liable to a fine. The benefit of the system to the public health is altogether illusory, because although the spread of an epidemic may be checked in a few instances, in many more people who suspect an infectious disease are careful not to call in a doctor, lest he should report them, and it is practically impossible to bring those people under the law, first, because they are not found out, and, secondly, because if they were they would probably escape on the plea that they did not know what the disease was. I have known dairy keepers to have children with scarlatina, and, suspecting the disorder, to bring the child out to a doctor; when he stated the nature of the disease they simply refused to give their address, and nursed the child probably at the back of the shop. To such an extent has this feeling grown that all such people have now simply a horror of bringing a doctor to their place, and will do anything to avoid it.

The sanitary authority, I submit, cannot do much to check the ravages of disease until it is accurately informed of what diseases exist in its midst. It has now no means of knowing except in the case of a few infectious diseases, unless from the Registrar-General's returns. But these returns necessarily come too late, and they deal only with the immediate cause of death. Each of us may suffer a hundred ailments, possibly preventible and certainly discomforting, but we shall augment only one item in the Registrar-General's mortality list, and that surely will give an inadequate account of our clinical history.

I submit that a far more satisfactory mode of notification of disease would be if the sanitary authorities got from each practitioner in the district an account each week of the diseases which he had treated. Something like this is done in the Poor-law system, each person's ailment is noted and the presence of any particular disease can be seen at once; but I do not know that any special statistical use is made of those lists of affections. If the practitioners were furnished with lists containing the usual heading of diseases—as of fevers, influenza, whooping-cough, dysentery, syphilis, gonorrhœa, septicæmia, pneumonia, phagedæna, tuberculous and parasitic diseases, rickets, anæmia, alcoholism, &c., he could fill up the particulars in a few minutes; and if a small fee were forthcoming for punctual attention, the medical officer of health would have a clinical picture of the state of health in his district every week, and could at once cope with the more prevalent diseases.

The suggestion, then, is that the notification system should be extended to diseases of every class, but that the individual names be not disclosed except where already required. Thus much valuable information about venereal diseases, abortions, alcoholism, and several other important social factors can be obtained which practically make no show on the Registrar-General's returns.

This system prevails already, I understand, in many important cities. Thus even so far away as Buenos Ayres a weekly return can be had, in English or Spanish, of every case of disease treated in the city, and at a glance one can see that type of ailment which needs attention most, and is wreaking most havoc.

It is an established axiom in preventive medicine that the petty meddling of the private practitioner, however individually able, can do nothing to lower a death-rate. This is the task of a sanitary authority having extensive powers and an able staff. But those powers and the efforts of the staff are often rendered futile because they have no adequate means of becoming aware of the state of public health at any given moment, their only means of information being a few notifications of some of the infectious diseases and the mortality returns. Obviously, either of these, or even both of them, is inadequate to give such a picture of the amount of sickness in a locality at any moment that effective steps can be taken to check it. The mortality statistics of the Registrar-General are prepared at enormous expense, and the notification of infectious diseases also causes great expenditure, but we consider the money well spent if it enables us to grapple the better with disease. A necessary complement of these returns is that we should have a means of knowing, week by week, what diseases were prevalent, whether infectious, or fatal or not. These would be, on a general scale like the hospital statistics which have proved of such service; but hospital statistics are vitiated by the fallacy of being true only of a picked class and under special circumstances.

It must be insisted on that the disclosure of the class and kind of disease which a physician is treating involves no breach of confidence; there is no need to give the names of the parties suffering; it suffices to have something like an accurate account of the number of cases of a disease in order to show its prevalence. It will also probably have a healthful effect on certain practitioners that they would be forced to make a definite diagnosis; we are all prone to a non-committal attitude as to diagnosis, which induces slovenliness of treatment, and, therefore, needs correction.

In brief, the improvement in the notification of diseases which I have to suggest is, that *all* diseases be notified to the sanitary authorities at regular intervals, and that a small fee be paid to the practitioner for his trouble. Thus the sanitary authorities become at once cognizant of all the forms of disease which exist in their locality, and can take steps to check their progress.

ANTI-PUTRESCENT MEDICATION BY SPECIALLY-SELECTED LACTIC ORGANISMS,

WITH REMARKS ON

MUCO-MEMBRANOUS ENTERO-COLITIS.

By M. DUTOUR, M.D.,
Of the Faculty of Medicine of Paris.

[SPECIALLY TRANSLATED FOR THIS JOURNAL.]

THE biological researches of Professor Metchnikoff and his followers have not only served the purpose of calling attention to the dangers of intestinal putrefaction, but they have indicated the lines on which they may be fought.

The remedy is not to be found in mineral chemical agents but in the domain of bacteriology. We must destroy the putrefactive agents by other varieties of micro-organism, carefully chosen so as to obtain them in a state of absolute purity, taking care also to prefer varieties which produce large quantities of lactic acid so that the latter, being produced in a nascent condition within the organism, may bring about antisepsis and effect a salutary change in the humours.

According to Metchnikoff and his school we must combat the deleterious microbes of putrefaction by the aid of judiciously-selected lactic microbes. The latter, however, must fulfil certain conditions so that in practice we may not be exposed to the drawbacks inherent to kephyr and yaourt as these not infrequently comprise organisms injurious to the human economy which determine abnormal alcoholic fermentations.

Researches carried out on these lines at the Paris *Institut Pasteur*, in which the Bulgarian bacillus which is a powerful producer of lactic acid, was associated with certain selected paralactic microbes, resulted in a combination that exerts a most remarkable anti-putrescent action, and which is perfectly harmless, viz., lacto-bacilline, now commonly employed in contemporary therapeutices.

This remedy must therefore be taken to represent the outcome of a long series of investigations undertaken by Professor Metchnikoff's pupils, and we must emphasize the fact that it represents especially "the superior action of the Bulgarian bacillus without the least trace of abnormal fermentations" (see Etudes sur La Nature Humaine. Paris, 1906; Essais Optimistes, Paris, 1907).

It is necessary on the present occasion to recall the physiological investigations on lacto-bacilline. Bertrand and Weisweiller demonstrated the fact that, alone among the lactic ferments, the Bulgarian bacillus elaborated from 25 to 30 grammes of lactic acid, transforming into this substance the whole of the milk sugar. M. Belonowsky, quoted by Metchnikoff, showed that mice which were subjected to the action of this bacillus thrived better and were more prolific than the others and that at the same time all fœtor disappeared from their dejections.

We will not insist on the protective influence which the authors of this treatment attribute to it as predisposing to longevity. Following Metchnikoff, who dwelt particularly on the absolutely hygienic part played by lactic ferments, Maurice de Fleury in his turn drew attention to the prophylactic, *i.e.*, curative, action of these organisms (*see* Annales of the Institut Pasteur, No. 12, 1906; Essais Optimistes, pp. 221, 222; Quelques Conseils pour Devenir Vieux. Paris, 1907).

On the present occasion we are more particularly interested in the clinical effects that may reasonably be anticipated from this substance, and our object is to bring to the notice of practitioners the results that we have obtained in the treatment of seven cases of muco-membranous entero-colitis.

To begin with we must be careful to enjoin the consumption of a sufficient quantity of sugar whenever we propose to employ the ferment treatment. Sugar, in fact, constitutes the indispensable food of these protective microbes, and it is from sugar that they elaborate the lactic acid. A suitable dietary must also be imposed, indeed, the patient must become vegetarian or semi-vegetarian for, in spite of Cohendy's statement that the anti-putrescent action of lacto-bacilline is manifested independently of all dietetic restrictions, if we wish to obtain immediate results we must avoid introducing into the intestine alimentary substances which are peculiarly prone to decomposition (Comptes Rendus de la Société de Biologie, No. 13, 1906).

Of the four therapeutical forms in which lacto-bacilline is presented—curdled milk, peptonised bouillon, a powder, and tablets; the last two were principally employed by us in the following doses: half a tube of powder in the twenty-four hours, in two parts, given at the end of the two principal meals; three or four 30cg. tablets daily, as above, associated in both instances with the ingestion of some sugar-containing food.

The results of this treatment were produced in very short time. Beginning with diminution of the diarrhœa and the pain, the fœtor of the stools was diminished in a marked degree. In some instances, however, there is an initial phase of constipation, but this never lasts long and need not be taken into account.

As a rule, in the course of a fortnight, the glairiness disappeared, and although the elimination of false membranes persisted somewhat longer they were rarely present after a month's treatment, whereupon all the symptoms of entero-colitis subsided.

In two instances there were acute exacerbations accompanied by a good deal of pain. On palpation the colon could be felt to be spasmodically contracted and the diarrhœa was obstinate and extremely fœtid. In these cases we had recourse to the peptonised bouillon, two wineglassfuls daily, the patient being placed on a rigid diet wilh daily irrigation of the bowel. In both cases the acute attack subsided within a week.

It is obvious that the peptonised lacto-bacilline bouillon exerts very rapid effects, and is better adapted for the treatment of acute cases than the tablets, but in chronic affections the tablets are preferable and, moreover, they are easier to make use of.

In our opinion the complete cure of old-standing cases of entero-colitis, which took place in about six weeks on an average, can only be explained by a salutary modification of the microbial contents of the intestine. It is, however, possible that some share in the effects must be credited to the hyper-secretory influence on the liver which most authors ascribe to lacto-bacilline. However this may be, many observers have noted this curative action, among others, Combe, of Lausanne, Brochet, Jeanselme, Rodenthal, Nigoul, Gottschalk, etc., who have all published cases in which favourable effects were noted.

All the other manifestations of intestinal decomposition appeared to be improved by this lactic ferment. We have given it in the treatment of infantile diarrhœa, constipation and ordinary colitis, as well as in the tuberculous form when the patients were anæmic. Such patients do better on curdled milk, which possesses remarkable nutritive properties, in virtue of the solubility of its caseine and phosphates.

To sum up, in combating intestinal putrefaction and especially in the treatment of chronic enteritis nothing has appeared to us to give as good results as lacto-bacilline. In any event our personal experience enables us to state that in the last-named affection lacto-bacilline appeared to act more energetically than any treatment previously employed. As to the influence of the Bulgarian bacillus with paralactic bacilli in the prophylaxis of senility and arterio-sclerosis we are not at present in a position to make any statement, but we do affirm without hesitation its clearly curative action in enteric troubles and its absolute innocuousness.

CLINICAL RECORDS.

MALIGNANT DISEASE OF OVARIES AND VERMIFORM APPENDIX OCCURRING IN A PATIENT, AGED 69. (a)

By J. H. Swanton, M.D., M.Ch.

Physician for Diseases of Women, Kensington General Hospital, etc.

The patient, A. J., from whom these tumours were removed, was a married woman, æt. 69, who was engaged in domestic work. She came to hospital in January, 1907, complaining of dysuria and a slight red vaginal discharge. The only previous illness was influenza, of which she had several attacks.

Her menstrual history presented no unusual deviation, and the menopause occurred more than fifteen years ago without any complication. Although she had been pregnant nine times, only three children were living; there had been two premature births, one stillbirth, and several miscarriages before the birth of the last child. The youngest living was æt. 30, and the eldest 35.

Her present illness began in July, 1906, with a scanty blood-stained vaginal discharge. In November, 1906, there was incontinence of urine and a consciousness of failing strength, but there was no pain.

The patient was well-nourished for her time of life. The mammæ were atrophied. The abdominal wall was distended and resonant, but the veins in the lower portion were distended. On deep palpation a tumour was felt low down in the true pelvis, situated centrally and fixed.

The vulvar outlet was relaxed and the vagina atrophic. The uterus was enlarged and directed forwards, but moved with the mass situated posteriorly.

The utero-rectal pouch was occupied by an irregular mass firmly fixed in the pelvis, and extending towards the lateral walls. On rectal examination the tumour was found to extend laterally, but the upper limit could not be reached.

The diagnosis was that of a uterine fibroid undergoing malignant degeneration.

The radial arteries were thickened, the pulse infrequent and intermittent. A basic systolic bruit was heard over the præcordial region. Early in March, 1907, she had an attack of bronchitis. When seen again, the growth was found to have increased towards the left side and was obvious on inspection of her abdomen. Her stools were frequent, liquid, and defæcation was painful. There was œdema of her left foot. At the end of March, 1907, she was admitted into hospital, when the greatest abdominal circumference was 82 ins., the distance from the right anterior spine of the ilium to umbilicus was 6 ins., and the corresponding measurement on the left side was 6½ ins.; from upper margin of symphysis pubis to umbilicus, 6 ins. The upper limit of the growth was 4 ins. above the symphysis.

The upper part of the growth was irregular and some limited fluctuation was felt on the left side. There was some free fluid in the abdomen and palpation caused pain. On vaginal examination the growth was found almost on the pelvic floor; the external os was behind the symphysis and a blood-clot was found extruding. Early in April, 1907, I performed abdominal cœliotomy by a median vertical incision, when about one pint of ascitic fluid came away; the great omentum was adherent to the tumour occupying the pelvis.

After separating the adherent omentum, two tumours partly cystic and partly solid, were found filling the pelvis, firmly adherent to the surrounding structures, but more so on the left than the right side. The uterus was 4 ins. in length, hyperæmic, and slightly attached to the tumour on the left side by a whitish band, which was easily broken down. The adnexa could not be identified on either side.

The tumours were in contact in the cavity of the pelvis, and each consisted of a solid and cystic portion. After separating all adhesions, the tumours were lifted out, the pedicles ligatured and removed. On making an examination of the vermiform appendix, the meso-appendix was puckered in one part and the consistence of the adjacent wall increased so as to necessitate removal.

There was little hæmorrhage throughout the operation. The abdominal wall was closed by a continuous cat-gut suture for the peritoneum, and interrupted silkworm gut sutures for the muscles, fasciæ, and skin. The temperature rose on one occasion to 104°, but fell to 99° within twenty-four hours. After the fifth day, the stools became frequent and loose for three days, and then were passed once daily afterwards.

The tumour on the left side was 6½ ins. in length and 2½ ins. in width. The surface was irregular, of dusky hue, and covered with tags of tissue. On section, numerous cysts were found in the periphery containing a limpid reddish fluid. The central portion was mottled, white and red, with processes radiating out towards the cystic portion. The tumour on the right was 4½ ins. by 4¾ ins., and presented a more irregular surface, while the cysts were larger and situated inferiorly. The internal structure was similar to that on the left side. The vermiform appendix was situated mesially to the cæcum, directed obliquely upwards to the left, and 3 ins. in length.

(a) Read before the British Gynæcological Society, July 11th, 1907.

On microscopical section, after staining with hæmatoxylin and eosin, the growth was seen to consist of oval spaces lined with several layers of columnar cells passing through the basement membrane in some places, and encroaching upon the lumen. These cells were in different stages of degeneration. In some of the spaces a colloid material was found occupying the central portion, and in these the layers of lining cells were not so numerous. The interstitial tissue consisted of connective tissue undergoing hyaline degeneration, with many polymorphonuclear cells scattered throughout it.

A transverse section of the appendix showed the same variety of growth invading the muscular layer and passing in towards the submucous. This growth in the appendix probably arose by implantation rather than by metastasis from the original. The genesis of this growth would appear to have been from a previous cystic condition of the ovaries, which became the seat of malignant degeneration after the menopause. The patient was discharged on the twenty-fourth day after admission, and the last report was that she had resumed her domestic duties and had developed a ravenous appetite. There is, however, little prospect of ultimate recovery, as this type of growth is particularly malignant.

THE OUT-PATIENTS' ROOM.

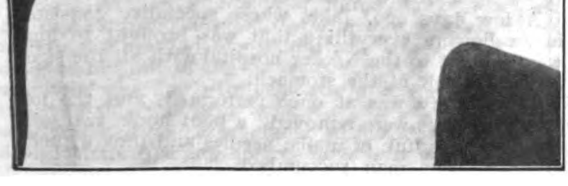
GREAT NORTHERN CENTRAL HOSPITAL.

Congenital Elevation of the Scapula (Sprengel's Deformity).

By Arthur Edmunds, B.Sc.Lond., M.S., F.R.C.S.

Among the out-patients was a woman, æt. about 50' who came complaining that she had swallowed a threepenny-bit. There were no obstructive symptoms, and there was no evidence of any impaction of a coin in the œsophagus. The patient was obviously extremely hysterical—indeed, almost melancholic; but in the course of the examination it was discovered that she was suffering from the deformity of the scapula first described by Sprengel, and named by him Congenital Elevation of the Shoulder.

The condition had never inconvenienced the patient in the slightest degree, but on examination it was seen that the right shoulder was considerably higher than the left. The upper border of the scapula could be felt from the front apparently as a projection forward of this part of the bone. Extending from the upper part of the scapula to the occipital region was a thick mass of muscle composed mainly of the upper fibres of the trapezius. This mass of muscular tissue was not only thicker but denser than normal, as if a considerable portion of the muscular fibre had been converted into fibrous tissue. Below the scapula the muscles of the back were not very markedly affected, and the inferior angle of the scapula did not project much beyond the one on the opposite side. Movements at the shoulder-joint were quite normal, but the movements of the scapula upon the trunk were distinctly limited, the patient being unable to raise the arm above the right angle, and it was easy to make out that further progress was prevented by the superior angle of the scapula impinging upon the cervical spine. This point was confirmed by a skiagram. Mr. Edmunds remarked that this condition was comparatively rare and that although many cases had been described in children, very few had been described in adults, and the present case was valuable and interesting as showing the ultimate condition of this deformity. The causation of the deformity has not been definitely settled, but it is extremely significant that a large number of the cases have been born with a posterior displacement of the arm. As many of these intrauterine displacements are present comparatively early and are maintained by a deficiency in the liquor amnii, it is very probable that they play an important part in the production of deformities. Another explanation is that the muscles connected with the lower portions of the scapula, namely, the rhomboids and the inferior fibres of the trapezius, are atrophied, allowing the upper muscular fibres to pull the scapula upwards. The fact, however, that some of these cases show a scapula which resembles in shape the type of bone found in the ungulata (sheep and oxen) in which the long axis of the bone is parallel to the spinous process, the supra-and infra-spinous fossæ being almost equal in size, suggests that some developmental error is also present.



These animals also possess a large supra-scapula and in some cases of Sprengel's deformity a well-developed bone is found extending from the superior angle of the scapula to the spine, possibly representing a suprascapula. In the present case there was no bone of this description present, and the scapula was normal as regards shape and size. The hooked condition of the upper border of the scapula which could be felt above the first rib was due merely to the position of the scapula, which, as it is drawn upwards, rides forwards over the curve of the upper end of the thorax.

Treatment in these cases is not very satisfactory; any attempt to divide the muscles and bring the scapula into line with the opposite side should not be attempted, the muscles being usually so contracted and sclerosed that an extensive operation would be necessary. Even if this could be satisfactorily accomplished the weakness of the opposing muscles would lead to a recurrence of the deformity. If a suprascapular bone be present it should be removed and some cases have been benefited by removal of the upper angles of the scapula, allowing the arm to be raised above the right angle.

OPERATING THEATRES.

WESTMINSTER HOSPITAL.

Nerve Transplantation for Paralytic Talipes Calcaneus.—Mr. A. H. Tubby operated on a case of talipes calcaneus due to infantile paralysis. The patient was a child, æt. 5 years, who had attacks of infantile paralysis in infancy affecting the right leg. A large measure of recovery had taken place but there was considerable loss of power in the gastrocnemius and soleus. On examining the movement of the foot it was found that the child was unable to plantar-flex or point the foot fully. The ankle could not be extended beyond a right angle. By electrical test it was noted that the muscles reacted to faradism, but reaction to galvanism was feeble, thus showing the degeneration of a considerable portion of the fibres of the large calf muscles. The child had been in the hospital for seven weeks, during which time massage and electrical treatment had been assiduously carried out, but no improvement had taken place. Photographs were shown indicating the range of movements at the ankle. Mr. Tubby pointed out that the nervous supply to the gastrocnemius and the soleus is by two branches of the internal popliteal, one nerve passes to the outer head of the gastrocnemius and the other nerve to the inner head of the same muscle and supplies also the soleus. These branches have a fairly long course and can be separated for some distance up the main trunk without interfering with the remainder of the nerve fibres in it. The child having been duly prepared and every precaution taken, inasmuch as one of the main features of success in these operations is to obtain primary union, a vertical incision three inches long was made in the middle of the popliteal space, and the internal and external popliteal nerve trunks were defined. By a little careful dissection the nerves passing to the gastrocnemius and soleus were found and isolated; sterilisable electrodes were then used for stimulating these nerves and their identity confirmed. Finding that contraction of the affected muscles followed stimulation the next steps of the operation were proceeded with. The length of nerves required to bridge the distance between the internal and external popliteal nerves was estimated, and just below the points of intended division a strand of the finest sterilised gut was passed through the nerves These were then divided from their origin at the internal popliteal. The next step was to prepare the external popliteal for the reception of the nerves to be transferred. In doing these operations Mr. Tubby said the best instruments were fine tenotomy knives and forceps, such as are used in ophthalmic surgery. Care must be taken not to nip the nerve trunks with forceps under any circumstances. A small vertical incision was made with a tenotomy knife through the epineurium of the external popliteal nerve in two places until white matter began to exude. The nerves to be transplanted were then brought across to these incisions and their proximal ends inserted and secured by the strand of gut previously passed through the nerves. The greatest care was taken to see that the tips of the transferred nerves were actually imbedded in the external popliteal trunk. The external wound was then closed and the limb put on a splint. Mr. Tubby remarked that previous experience of two similar cases operated on by him, and shown at the Clinical Society last session, had proved that this operation was a satisfactory one and was justifiably undertaken when ordinary measures, such as massage and electricity, had failed. In one of the cases a partial recovery of power in the gastrocnemius and soleus had taken place, and in the other case the recovery was nearly complete. In the first instance no signs of restored power were seen till seven months had elapsed, but in the other case return of power was noticed earlier, in fact, four months after the operation.

At Edinburgh University last week, the honorary degree of LL.D. was given, in his absence, to Dr. William Bayard. Sir Ludovic Grant said Dr. Bayard graduated at Edinburgh in 1837, and next month he would attain the age of 90. Dr. Bayard was in St. John's, New Brunswick, in vigorous health, actively prosecuting the duties of his profession He was the patriarch of the whole tribe of Edinburgh graduates throughout the world.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, July 28th, 1907.

Sued for Malpraxis.

An interesting case between doctor and patient has just been decided in favour of our confrere in the Paris Courts. A young lady was treated for appendicitis in the usual way; the icebag over the seat of the inflammation and opium by the mouth. Her attending physician omitted to place a layer of flannel between the ice and the skin and the consequence was congelation of the skin (the ice was kept on for twenty-five days!) with subsequent sloughing. She recovered from the appendicitis, but remained three months under treatment for the large superficial sore.

Two thousand pounds damages were claimed, but the Court gave judgment for the defendant. From the testimony voluntarily given by some of the highest medical authorities in favour of their confrere, the judges concluded that the doctor was not guilty of negligence, that the malady the patient suffered from was extremely dangerous and required heroic treatment.

All the same, were it not for the good backing he received, our friend would not have got off so well, In any case it is elementary prudence to place the ice-bag over one or two folds of flannel, and this he will not fail to do another time.

Moved with pity at the thought of suffering humanity constantly falling into the hands of those ogres, otherwise denominated medical men, a rich man in Paris wrote letters to the Charity Commissioners offering the sum of one million francs with a view of organising a system for controlling the acts and gests of the hospital staffs, imposing the condition that no medical man should be on the committee of this extraordinary organisation, which otherwise was to be composed of competent men of science!

The strange proposition on the part of a seeker of notoriety was treated with the merit it deserved, and the Charity Commissioners seized the opportunity for pronouncing their sympathy with the physicians and surgeons of the Paris hospitals and expressing their esteem and confidence in the staff whose devotion and scientific knowledge were never found at fault.

Early Diagnosis of Typhoid Fever.

Prof. Chantemesse, who discovered the serum of typhoid fever, made an interesting communication this week before the Académie de Médecine on a method for the early diagnosis of typhoid fever. He succeeded in producing a toxin which, when an infinitesimal dose is dropped into the eye, produces an inflammatory reaction of more or less intensity. Where the fever is not of a typhoid nature the reaction is very slight, lasting only two or three hours. The conjunctiva becomes red and the eye smarts a little. If the case is really one of typhoid fever the inflammation is almost intense, accompanied with more or less pain and epiphora. After two or three days, however, the eye returns to its normal condition without leaving any trace of the disturbance.

An Ostrich Stomach.

A few days ago, Jake, whose speciality consisted in swallowing everything that was brought to him, was brought to the Necker hospital with all the signs of perforation of the stomach.

Laparotomy was at once performed, and the following articles were removed: a boot hook, two steel chains, a handful of nails, needles and pins without number. The man succumbed.

Such cases are not rare among a certain class who exhibit themselves in low class music halls or on the fair green.

Some time ago a young girl who exercised the profession of swallower of pins, was presented to the Medical Society. For three years she went from café to café and before the public who likes this kind of spectacle, swallowed pins, broken glass and, above all, nails. Her health did not seem to suffer much and beyond a few colics attributable to a pin or nail badly placed, she enjoyed good health; the incongruous objects were expelled naturally.

In many cases these foreign bodies have remained weeks and months in the stomach without causing inconvenience.

It will be remembered that in 1866 a Japanese surgeon removed a tooth-brush from the stomach of a man which he had swallowed fourteen years previously.

Procreation of Sexes at Will.

M. Hurry, of Geneva, pretends that if conception takes place four or five days before the appearance of the menses, the child will be a girl. If it takes place five or six days after the menses, the child will be a boy.

An agriculturist presented his cows to the male two or three days after the rut to have a male and the first day of the rut to have a female. His intentions were realised twenty-nine times out of twenty-nine experiments.

Dr. Guiard reports thirty-five cases in which the law of Hurry was verified thirty-one times.

GERMANY.

Berlin, July 28th, 1907.

At the Medizinische Gesellschaft, Hr. Ewald showed a patient who had suffered from

Recurrent Hæmorrhages

from ulcer of the stomach, in which all the remedies tried, including escarine, had failed. In consequence of this, gastro-enterostomy was performed, with the result that no more bleedings took place.

Hr. Placzek communicated a note on

Circumscribed Adhesive Cerebral Arachnitis.

In the case of a young lady, æt. 25, the speaker had diagnosed a tumour in the right posterior cerebral fossa. The symptoms on which the diagnosis was based were the following: Vomiting, headache, giddiness, altered gait, inclination to fall to the right, almost complete paralysis of all the external ocular muscles of both sides, with implication of the frontal branches, and complete paralysis of the right side of the face. An operation performed by Krause showed a meningeal cyst of the under surface of the right cerebellar hemisphere, out of which an enormous quantity of liquor escaped. All the paralytic symptoms at once subsided, and the general condition became good. Then, on the tenth day after the operation, the temperature went up with sharp rises to 40° C. and more, then a rapid fall, followed by several days with a normal temperature. This condition lasted for several months and was occasionally accompanied by rigors and vomiting. In sharp contrast to this the general condition was excellent. As healing took place normally, and as every imaginable cause for the hyper-pyrexia could be excluded, there only remained the assumption that pressure on the medulla at the operation was the cause. The importance of the case lay in the clear determination of the fact that circumscribed collections of fluid in the soft cerebral membranes might set up symptoms similar to those of the tumour group.

Hr. F. Krause, who had performed the operation in the case, showed a series of projection pictures illustrating the method of procedure he now followed in cases of tumour of the posterior cerebral fossa. The skin and bone flap were naturally different, according to which side was being exposed. In that case there was supposed to be a tumour in the right posterior fossa. After opening up the dura it was seen that it did not project, and that it pulsated; it was thickened. It was opened, and, after being reflected back, the cerebellum was palpated. Nothing was found, and it was only near the medulla oblongata that a cyst was found, which contained about 150 cm. of clear fluid. After this had been emptied, cerebro-spinal fluid escaped, which up to then had not done so in any quantity. The cyst lay in the meshes of the arachnoid. That an adhesive process was present in the parts was shown by the fact that adhesions were present on the surface of the cerebellum that had to be dissected off.

The meshes of the arachnoid contained a good deal of fluid in the normal state, but under ordinary conditions it was diffuse; if adhesions were present anywhere, however, collections of fluid cysts formed The acute form of this condition had long been known to the aural surgeon. The existence of the condition in the chronic form could no longer be doubted. These cysts presented all the symptoms of cerebral tumours and had to be treated by operation.

Hr. Loewenthal related a case of amblyopia from poisoning by methyl-alcohol. A workman, æt. 29, three days after drinking a small quantity of methyl-alcohol, besides the general symptoms of poisoning, showed atrophy of the optic nerve in its early stage. Although the general symptoms had disappeared the sight had not returned, and the man was quite blind. The speaker concluded that methyl-acohol was a poison with strong elective affinities, which was very fatal, and the very few that survived remained blind. Its poisonous property was developed not only when taken internally, but also when applied externally, and when the vapour of it was inhaled. Individuality played the same part here as in other poisons. A dose of 8 cc. might be a very serious one for individuals with a predisposition to be affected by it.

AUSTRIA.

Vienna, July 28th, 1907.

Gall-Stone Colic.

Haberer presented a female, æt. 47, from Eiselberg's wards, who had suffered for fourteen years from gall-stone colic, which resulted in absolute closure of the ductus choledochus near its entrance into the duodenum, where the ulceration and finally the cicatrisation had so contracted the duct that absolute closure was the result.

Haberer had performed choledocho duodenostomy with an excellent result by maintaining temporary drainage of the lever for the bile during the period of healing. This was considered a crowning feat over the ravages of cholelithiasis.

Histological Changes in Stomach.

Bondi next gave the members a long description of the various changes that took place in the walls of the stomach in cases of diabetes when appearing as a morbid change and when induced by the administration of phloridzin. From microscopic preparations of the mucous membrane of the stomach in a case of pancreatic diabetes, as well as that from the stomach of a healthy dog, which had been treated with phloridzin, the glands contained drops of fat while the covering epithelium was quite free. Similar changes were present in the crypts of the small intestine as well as troma of the shaggy epithelial.

It was shown at a previous meeting that these changes took place in the liver in pancreatic and phloridzin diabetes, but not in the stomach and bowels, this is incorrect. In support of this condition Lombroso some time ago found by analysis that more fat came from the bowel of the pancreatic dog than from the healthy animal, this he could not account for at the time, but can now understand from the histological proofs. This fat is not obtained from the food taken into the alimentary canal, as dogs when hungered give the same result.

Erosions from Caustic Soda.

Preleitner has collected all the cases from the eight hospitals in Vienna that have been admitted within the last seven years, numbering 362 cases, mostly in children Of these 18.6 per cent. died in consequence of the erosion, 93.3 per cent. of the remainder suffered from cicatricial narrowing of the œsophagus, 10 per cent. having to be operated on in the form of gastrostomy to admit of alimentation and distension of the canal with bougies. Such a large number of children should be protected by some legal enactment modifying the sale of strong caustics and, if they must be sold compelling them to be delivered in a different form of bottle that might arouse caution.

Teleky quite agreed with Preleitner as he had drawn attention to this great sacrifice of life six years ago, but failed to arouse the government to action. It is scarcely possible to prohibit the sale of these powerful caustics, but they can be sold with more safety to the public than they are at the present time, by suitable bottles and attaching proper directons. It is scarcely possible to go as far as Preleitner would have us, as probably other more powerful substitutes might take their place in the domestic cleansing armamentaries.

Aggressin and Toxin.

Bail, of Prague, has been investigating the various fluids in disease, and assures us that there is always present the aggressive and toxic fluid as seen in diphtheria, where the antitoxic and anti-aggressive both exist. He affirms that all the semi-parasitic bacteria such as typhoid and dysentery have these two fluids in common which can be individually separated, though this is sometimes difficult. In the toxin itself there is a component part which is not poisonous of itself but is powerful in laming or weakening the cellular function which opens the path for the operation of the toxin. In the semi-parasitic group this aggressive immunity is equal to an antitoxin.

Lipomatosis.

Kirsch in a long article on this subject enumerates the various causes of super-nutrition, engorgement of vessels occurring in the anæmic as well as the healthy. He now adds the climacteric changes, juvenile degeneration, morbid changes in the genitals and metabolism. The most important of all are chronic alcoholism, syphilis, and the pastose or lymphatic form of scrofula. Balneo-therapeutics with chalybeate waters should be prescribed.

HUNGARY.

Budapest, July 28th, 1907.

At the recent meeting of the Budapest Interhospital Association, Dr. Boros read a paper on

Swelling of the Testis and Epididymis.

He classifies the enlargements of the testis and epididymis under the following heads:—(1) Acute (*a*) Gonorrhœa almost invariably involves the epididymis, seldom the body of the testis, or orchis proper. (*b*) Trauma almost always involves the body of the testis proper and but seldom the epididymis (*c*) Epidemic parotitis, or mumps, as a rule, affects only the orchis, or body of the testis proper. (*d*) Cystitis of non-gonorrhœal origin is a frequent secondary complication, as is also inflammatory enlargement of the epididymis. (2) Chronic: (*a*) Tuberculosis is the most frequent cause of chronic enlargement and, as a rule, first involves the epididymis, especially the tail of this portion of the organ, and later involves the body of the testis proper. It gives rise to a peculiar, nodular, very firm condition of the epididymis, feeling like a series of beads, and often extending in a similar manner up the vas deferens. (*b*) Syphilis in the majority of cases involves the body of the testis proper, and but rarely the epididymis. There are, however, exceptions to this, in which tertiary syphilis involves the epididymis, as well as the body of the testis. (*c*) Tumours or neoplasms of the testis may be either benign or malignant; the benign belong to the class of adenomas or chondromas, the malignant most frequently to the class of sarcomas.

Clean Milk Movement in Budapest.

The city health officer recently inaugurated a crusade for pure milk. The members of the city board, through personal visitation of dairies within and outside the city limits, acquired a first-hand knowledge of the situation that enabled them to effectively squelch the offending dairymen and their political backers in an attempt put forward to have the requirements and penalties laid down by the board set aside. From a number of analyses by the city bacteriologist, the board has decided that a dairy selling milk containing more than 500,000 colonies of bacteria to the cubic centimeter shall be the subject of investigation—surely, by the widest stretching of official amiability, no unreasonable standard. The situation is reviewed by a Budapest medical journal. There can be little doubt but that a large proportion of the vast number of digestive diseases among infants, with the many fatalities therefrom, can be traced to an impure milk supply. This being the case, it certainly becomes the duty of the municipality to safeguard the lives of the children of the citizens. The Board of Health and the health department officials deserve the hearty co-operation of all citizens in this much-needed work. Medical men, knowing the potent influence of an impure milk supply in inducing disease among infants, are especially obligated to lend the health authorities of Budapest their cordial co-operation and aid.

Dr. Roth read a paper on

Cancer of Intestinal Tract.

He said that cancer of the alimentary tract represents over 50 per cent. of all cancer. It used to be considered as most likely to develop in the middle life, and seldom under forty years. Now it is known to occur much earlier at times, and Dr. Roth saw a cancer of the rectum not long since in a new-born child. Often in these cases there is a little temperature and some tension of the rectus muscle, and while the surgeon is waiting for complete quiescence to do an interval operation, the cancer progresses too far for successful removal. Of the cancer of lower intestinal tract the most important sign is unsatisfied movements of the bowels. There is a sensation of unfinished business. Sometimes this symptom alone is sufficient to lead to investigation which discloses the cancer. Chronic constipation should not be treated for a considerable time, especially if it proves obstinate, without suspicion of cancer, and careful investigation along that line. In cancer of the intestines, where the new growth cannot be removed, the fatal current may be switched round the obstructions without the necessity for the inconvenience of an artificial anus. In inoperable cancer of the rectum, curettage followed by the cautery gives comfort and prolongs the patient's life.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

GLASGOW UNIVERSITY GRADUATION CEREMONIAL.

The annual summer graduation ceremony was held in the Bute Hall on July 23rd. The only honorary degree conferred was that of D.D. on the Rev. Ralph Wardlaw Thomson, Foreign Secretary of the London Missionary Society. After the ordinary degrees in medicine had been granted, the graduates were addressed by Professor Noel Paton, who dwelt on the effect of the study of medicine in stimulating a passion for the acquisition of knowledge for its own sake. The equipment gained during the five years of the curriculum was all too little to convert the raw recruit into a trained soldier, and he counselled the young graduates to delay their entry into practice until they had received further guidance and training. This might be got as resident in a hospital or by work in a laboratory, and he was glad to say that the two groups of workers, clinicians and laboratory researchers, were, year by year, coming more closely together. He spoke of the facilities for research now arising near home, making it unnecessary for students wishing to do research work to go abroad for that purpose, and in conclusion urged his hearers to be on their guard against following the easy path of quackery and humbug, and to follow the arduous path of straight dealing with themselves and their patients—the only path for honest men.

EDINBURGH UNIVERSITY GRADUATION CEREMONIAL.

This function took place in the MacEwan Hall on July 26th. The honorary degree of LL.D. was conferred on Wm. Bayard, M.D., St. John, New Brunswick, a graduate of the University of Edinburgh of sixty years' standing, who next month will attain the great age of 90, yet is still in vigorous health himself, and even engaged in ministering to the health of others. Dr. Bayard is the patriarch of Edinburgh Graduates, but not this, but the high esteem in which he is held by his Fellows, and the ennobling influence which he has exercised on the medical profession in New Brunswick, entitle him to the distinction his Alma Mater has conferred upon him. The graduates in medicine, law, and science having been capped and the various prizes and medals distributed, the address was delivered by Professor Sir Halliday Croom. He first spoke of the obligations which membership of the University brought with it, and of the inspiration which the traditions of their Alma Mater ought to give to the graduates. Not only this, but by enrolling themselves among the votaries of medicine they assumed responsibilities which only grew heavier as the years rolled on. Remembering that most of his hearers would become general practitioners, Sir Halliday Croom ventured on this parting advice: "First of all," he said, "however inconsistent this statement may seem to you, you must never have a practice. You must never think to have under any circumstances any vested right in your patients. Your patients constitute a practice just so long as you attend them, and no longer. They have a perfect right to demand the best of your skill and energy, and they have equally good right to demand the same from someone else the next time they require attendance. When you bid your patient 'Good-bye,' after attending him, it ought to be 'Good-bye,' and not necessarily 'Au revoir.' You must be independent of your patient, and your patient must be independent of you. The old-fashioned relationship of the family doctor, like that of the regimental surgeon, who regarded his clientele as his strict preserve, has in our day been much modified, and in this age of strenuous competition it is well that it is so." Speaking next of medical ethics, he asked: "What, in fact, are medical ethics? What are the ethics that regulate the conduct of one gentleman to another? Nothing, absolutely nothing, but the words to which we have been accustomed since childhood: "And, as ye would that men should do unto you, do ye also to them likewise." No rules or regulations, no code of ethics, no manual of etiquette, would ever be a better guide than abiding by the old formula. Sir Halliday Croom then urged that the art as well as the science of medicine should be cultivated. The problems yet unsolved were many. In anatomy there was still much to be done, especially in regard to the nervous system. In obstetrics, putting aside all other questions, the great subject of eclampsia, in its pathology and treatment, still remains unsolved, while gynæcology offers ample opportunity for original work. It remained also for some of them to complete in surgery the work of Lister and Pasteur.

After the ceremony, a House Luncheon was held in the Union. Last year, it may be remembered, Sir Donald Currie and Mr. Carnegie each promised £6,000 conditionally on the Union raising a similar sum. The total £18,000 being the sum required to pay off the debt on the extension. The Union succeeded in doing its part, but the estimates for the extensions were exceeded by £1,200, leaving the institution still indebted to that amount. About half the requisite amount of this second sum has also been raised, and at the luncheon Sir Donald Currie intimated his willingness to clear off the balance. The University union has indeed been fortunate in its benefactors; we doubt whether anywhere a more luxurious and well-managed club exists with so low a subscription.

ABERDEEN UNIVERSITY GRADUATION CEREMONIAL.

The Summer Graduation in Arts, Science, and Medicine was held in the Mitchell Hall on July 25th. After the degrees had been conferred, Principal Laing reviewed the present position of the university. In the quinquennium that had now nearly terminated, they had received from the Carnegie Trustees for equipment, teaching, and research, the sum of £45,000. With balance remaining, and the assurance that equally liberal treatment might be expected in future, there is reasonable prospect of further additions to the professional staff, and further contributions to the efficiency and sufficiency of university instruction.

LETTERS TO THE EDITOR.

THE GENERAL PRACTITIONER.

To the Editor of The Medical Press and Circular.

Sir, I have read with pleasure the articles that have appeared in the Medical Press entitled The General Practitioner. I quite agree with Dr. Tayler that it is very difficult for a medical man in a busy and exacting practice to find time for reading, and many of us have to do most of it in our broughams whilst visiting our patients, and undoubtedly there has been in the past a deficiency of books written specially for the general practitioner.

The young practitioner just entering into practice finds difficulties which have not been encountered by him during his hospital curriculum.

1st.—He is puzzled and does himself no credit when patients come to him complaining of minor ailments. He cannot do better than read carefully Dr. Leonard Williams's readable book on "Minor Maladies."

2nd.—During his hospital career he has seen the major operations of surgery performed by brilliant operators, nearly all of which he will never be called upon to perform in practice, but the management of these cases after the operation in the patient's house or in a private home he will be expected to look after. He will find Lockhart Mummery's "The After-Treatment of Operations" of great help to him.

3rd.—The general practitioner finds it difficult to decide what operations it would be safe and advisable for him to undertake. The recently published work, "Operations in General Practice," by Corner and Pinches, he will find a God-send. As these authors say: "At the beginning of his career the practitioner is prepared to do much surgery, but experience teaches him what he may safely undertake, and from what he should abstain, he has learnt that it is not so much the question of operation as the question of policy which must determine his professional action, a practitioner may refuse to do a so-called minor operation and the next day perform a major one."

If I had read this book twenty years ago I should have attempted to do many operations that I have not done, and left undone many operations that I have attempted to do. Having in a town practice the best operating surgeons within easy call, the trouble and anxiety of many of these operations is not in proportion to the comparative small fee that a general practitioner can charge.

In conclusion I wish to protest against the laboratory refinements that a student is expected to learn in these days. When in practice it will pay him better to subscribe annually to a pathological laboratory and have the sputum and diphtheritic membrane examined, the "Widal reaction" test, the "Diazo reaction" of urine, etc. done for him by pathological experts, and devote his time to more remunerative work.

I am, Sir, yours truly,
James Edwards,
Surgeon to the Liverpool Police Force, etc.

To the Editor of The Medical Press and Circular.

Sir,—The majority of the profession being general practitioners, your readers are no doubt mainly composed of the same class, and these all must feel under an obligation to Mr. J. Lionel Tayler for the series of suggestive papers he has contributed to your valuable journal. Successful general practitioners, the minority who are doing large practices among the wealthier classes, have no time to think of the difficulties of the mass of their brethren, whilst specialists and consultants have even less knowledge of and probably less sympathy with their case. If the general practitioner is to be helped into a better moral and material position it must be done by his own hand. Until an organised combination can be formed progress in any direction will remain impossible. An association of twenty thousand men speaking with one voice might easily make itself heard and felt. Of course the British Medical Association is already in existence, but I would ask what has it ever done to advance in any way the interests of the mass of the profession? It is almost entirely a co-operative society for the publication of a medical journal—a journal which rarely discusses or advocates reforms upon which the vital interests of the general practitioner depend. If these men will not set to work with determination to help themselves they may as well bear their grievances in silence—no help from outside will ever come to them.

I am, Sir, yours truly,
London, W. G. P.
July 25th, 1907.

DEBTORS AND CREDITORS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Can you comment on Judge Mulligan as reported in the *Cambridgeshire Times?* He has only recently been appointed in place of Judge Willis, K.C., and the latter judge and his predecessor, Judge Price, K.C., for a period extending over the last twenty years allowed debt collectors to appear and prove debts thus saving a lot of time and trouble to creditors and a lot of expense to poor debtors. Judge Mulligan, like the proverbial new broom, not only sweeps all this practice away but pretty plainly singles out four medical men insinuating that their conduct has been "nefarious." The practice for twenty years having been for the debt collector to get in his debt by small payments as convenient to the debtor as possible; when the debtor ceases to pay, the collector then gets written acknowledgement of his debt and the court always gave judgment for the acknowledged debt, the collector getting in his debt by instalments and charging 2s. in the £ to the creditor for his trouble—the debtor being put to no other expense than the court fees.

The way proposed by Judge Mulligan is the same as was in vogue some twenty-five or thirty years ago, before debt collectors were known, which was to give your list of debts to a solicitor who applied to such debtor by letter for which a fee was charged, then another fee for appearance in court, both fees being added against the debtor, and after judgment was obtained in court the debt was never followed up and, in fact, the county court for collection of small debts was a mockery, a delusion and a snare. Judge Mulligan by his inconsiderate action is making his court useless to small creditors, expensive to small debtors and an exception to every other court in the kingdom.

I am, Sir, yours truly,
MEDICUS.

SPECIAL ARTICLE.

ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

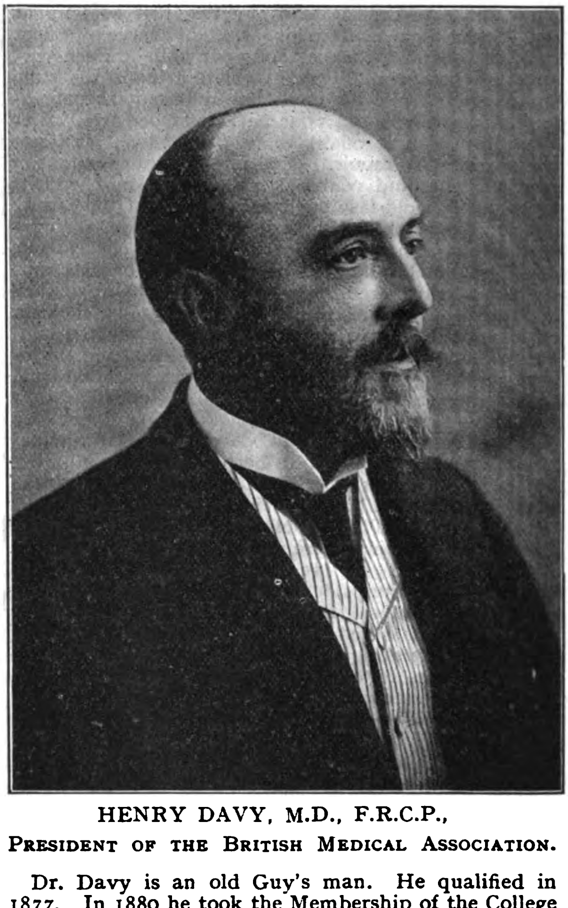
Exeter, July 27th to August 3rd, 1907.

[*From our Special Correspondent.*]

EXETER, the capital of England's West Country, is a peculiarly fit, proper and delightful meeting place for the annual picnic and yearly conference of so representative a body as the British Medical Association. This year's gathering already promises to be one of the most interesting and attractive of recent years. The meeting has opened under auspicious circumstances. Evidences of open-handed hospitality are apparent everywhere. Elaborate preparations have been made for the coming of the visitors. A promising programme has been arranged for those intent on the acquirement and dissemination of knowledge. The pleasure-seeking medicos from crowded cities and restless towns will find in this ancient cathedral centre a soothing and restful atmosphere; and in its surrounding country a veritable paradise of varied charms, which will provide restorative powers for the body as well as endless delights for the mind.

THE NEW PRESIDENT.

All will be wishful to tender hearty congratulations to the incoming President. Dr. Henry Davy has long been a prominent and honoured leader of Medicine in the West. His courtesy and consideration, knowledge and tact have won him wide popularity among both practitioners and patients. He has always maintained a high ethical standard and sought to further the interests of his profession and secure the benefits of science for the welfare of his fellow countrymen. His modesty and dislike for anything savouring of advertisement is well known by all his friends, but they will thank us for having secured, and here presenting, a photograph of the head of the B.M.A.



HENRY DAVY, M.D., F.R.C.P.,
PRESIDENT OF THE BRITISH MEDICAL ASSOCIATION.

Dr. Davy is an old Guy's man. He qualified in 1877. In 1880 he took the Membership of the College of Physicians of London, and was elected a Fellow in 1894. At his M.B. of London, in 1878, he took honours in Medicine, Obstetrics and Forensic Medicine, and, in 1882, proceeded to the M.D.

Dr. Davy has enjoyed much hospital experience, having served as House Physician and Resident Obstetric Assistant at his own school of Guy's Hospital, as House Surgeon at the Evelina Hospital for Children, and as Resident Clinical Assistant to St. Luke's Hospital for the Insane.

Settling in practice in Exeter he quickly made for himself a name and a place, and as Physician to the

Devon and Exeter Hospital and the Exeter Dispensary he exercised a wide influence on the local medical life of his city and its neighbourhood.

As evidence of his popularity in the profession it will be sufficient to note that when, in 1897, he was elected President of the South-Western Branch, every medical practitioner in Exeter contributed to present him with a peculiarly fitting token of esteem: his badge as a Sheriff of the City.

Dr. Davy has not only proved himself a popular and successful physician but has shown himself a valued contributor to Medical Science, having written on the pathological features of pernicious anæmia, movable kidney, pyrexial states in children and Addison's disease. His presidential address, an abstract of which we print elsewhere, in this number, affords abundant evidence that he views matters medical through a wide-angled lens and fully realises the important place that the physician and surgeon must take in the public life of the nation and the urgent need for an extension of scientific methods to all pertaining to the development of the best life of our country.

An Artistic Handbook.

Through the courtesy of the President we have been favoured with a copy of "A Book of the South-West," a handsome and charmingly illustrated work specially prepared for the delight and edification of medical visitors to our Western land. It will prove a revelation to many of the glories of the Delectable Duchy and the beauties of the Shire of the Sea Kings, and will long be treasured and, if we mistake not, be frequently used as an authoritative volume of reference. Mr. A. Wallis contributes a graceful and informing sketch of Devon and Cornwall, and Mr. A. T. Quiller Couch reveals something of "The Secrets of Cornwall." There is much valuable information on the physical and climatic features of the two counties and reliable directions regarding points of local interest and matters which may guide in the choice of a suitable health station for particular classes of patients. But the most striking and fascinating features of this most artistic volume are the many varied and admirably executed photographic reproductions. Everyone concerned in the production of this attractive and permanently useful momento of the Exeter meeting deserve warm congratulations and sincerest thanks. This volume will, for many a long day to come, serve to keep in remembrance the winning beauties of the West and very pleasant recollections of a thoroughly enjoyable annual meeting.

A Week's Programme.

Business, science and pleasure are amply provided for. The official representatives of the Association gathered on Saturday, the 27th, and continued their meetings on Monday and Tuesday, the 29th and 30th. On Monday the Mayor of Exeter held a reception in the Guildhall. Yesterday (Tuesday, July 30th) a service was held in the Cathedral at noon; in the afternoon a garden party was given by the Mayor; and at night the President delivered his official address. The Pathological Museum offers many objects of much interest. The Annual Exhibition of Foods, Drugs and Appliances promises to be well patronised. The work of the thirteen sections will doubtless prove to be of service, although there is no likelihood of the presentation of any startling novelties. Several discussions are likely to arouse heated argument. In so delightful a centre excursions, tours, and entertainments not unnaturally occupy a foremost place in the arrangements of the majority of the visitors. The list provided is most attractive. Only a real, old-fashioned Devonshire summer weather is wanted to crown the seventy-fifth annual meeting of the B.M.A. with complete success.

Dr. Vacher, the medical officer of Cheshire, in his annual report for 1906 says Stalybridge has the highest infant mortality rate in the county—206 per thousand.

OBITUARY.

SURGEON-COLONEL EDMUND G. McDOWELL, C.B., L.R.C.S.

We regret to announce that Surgeon-Colonel Edmund Greswold McDowell, C.B., died at Portland on July 26th last, at the residence of his son-in-law, Major E. W. Briscoe. The deceased officer was born on November 30th, 1831, and, after qualifying L.R.C.S.I. in 1855, entered the Army Medical Service as an assistant surgeon in the 44th Regiment. He was promoted surgeon on September 3rd, 1870, surgeon-major on March 1st, 1873, brigade surgeon in the Army Medical Department on August 4th, 1881, and deputy surgeon-general on March 4, 1886, retiring as a surgeon-colonel of the Medical Staff on November 30th, 1891. He served with the 44th Regiment in the campaign of 1860 in North China, including the action of Sin-ho and the storm and capture of the Taku forts (medal and clasp), and in the Egyptian war of 1882 (medal, 3rd Class of the Medjidieh, and Khedive's star). He also served in the Sudan expedition under Sir Gerald Graham in 1884 as principal medical officer, and was present in the engagements of El Teb and Tamai (twice mentioned in despatches, C.B., and two clasps). Besides one daughter he leaves two sons, Major F. McDowell, R.A.M.C., and Dr. D. K. McDowell, C.M.G., Principal Civil Medical Officer, Straits Settlement.

SURGEON-GENERAL ALEXANDER FRANCIS PRESTON, B.A., M.B.Dub.

We regret to announce that Surgeon-General Alexander Francis Preston, M.B., honorary physician to the King, late of the Army Medical Service, died last week at his residence in South Kensington, at the age of sixty-five Graduating at Trinity College, Dublin, in 1863, he joined the medical service of the Army the same year, and served in medical charge of the 66th Regiment in the Afghan War of 1880, when he was present at the affair at Ghirisk, the battle of Maiwand, where he was severely wounded, and throughout the siege of Kandahar, obtaining mention in despatches. He was promoted surgeon-major, with the relative rank of lieut.-colonel, and awarded the medal. In 1896 he reached the rank of surgeon-general, was temporary director-general of the Army Medical Department in 1901, and the following year was placed on the retired list. Surgeon-General Preston had been a honorary physician to the King since 1901.

REVIEWS OF BOOKS.

RECENT WORKS ON TUMOURS (*a*).

Mr. Sampson Handley's work on the dissemination of cancer is already well known to surgeons and pathologists by his Hunterian lectures, his Astley Cooper Prize Essay, and his contributions to the "Archives of the Middlesex Hospital." In the present volume (*a*) he has systematised his observations and conclusions in so far as they bear on the subject of Cancer of the Breast. The result is the most important work in surgery or pathology which has appeared in England for many years.

Mr. Handley starts with a criticism of the fashionable theory of the dissemination of cancer—the embolus theory. He shows, by citation of cases, how unsatisfactory the theory is. "Blood embolism must by its very nature, be an indiscriminate process; the cancerous emboli must be distributed impartially to all the organs. Why then in certain cases do the cancerous emboli gain a footing only in the abdominal organs, and in other cases only in the thoracic organs? The hypothesis of tissue predisposition does not meet the difficulty." . . . "Quite clearly it (the embolic theory) is not, standing alone, an adequate and complete explanation of all the remote metastases of cancer." . . . "Blood embolism, far from being a dominant and universal factor in the dissemination

---

(*a*) "Cancer of the Breast and its Operative Treatment." By W. Sampson Handley. London: John Murray. 1906. Pp. xii and 237. Price 12s. 6d. net.

of breast cancer, appears to be an event of exceptional occurrence, and one which, even when it occurs, is usually rendered ineffective by the destruction of those cancer cells which gain access to the blood stream." (Pp. 14, 15).

Having scotched the dominant theory, Mr. Handley proceeds to develop his own. He first describes the topographical distribution of the secondary growths in cases of cancer of the breast, and he next shows the paths by which the disease spreads. The main point of his teaching can be put in a short sentence—Cancer spreads by direct growth along the lymphatic channels. Moreover, this "permeation takes place almost as readily against the lymph-stream as with it." This growth Mr. Handley is able to demonstrate with the microscope. At some distance from the primary tumour "the principal lymphatic pexus of the part, the pexus which lies upon the deep fascia, is found permeated throughout, that is to say, its vessels are obstructed by the growth of lines of cancer cells along them" (p. 93). Somewhat nearer the primary tumour these permeated lymphatics are not found, a fact which seems to present some difficulty. It is shown, however, that the permeated lymphatics have been destroyed by a process of perilymphatic fibrosis. These various statements, though made boldly, are by no means unsupported. Mr. Handley marshals his evidence clearly and firmly, and it is all but impossible to impugn any of his views, however revolutionary they may appear.

Having acquired a knowledge of the mode of spread of cancer, Mr. Handley proceeds to study the particular case of the relation of visceral dissemination to cancer of the breast. He shows by purely anatomical considerations how readily the epigastric angle and, subsequently, the liver become affected.

Finally, he comes to the practical question of the application of his views to operations on the breast. As the disease spreads not at the level of the skin, but at the level of the lymphatic plexus on the deep fascia, it is obvious that in the removal of the part the deep fascia must receive special attention. The glands, however, are to be seen to as carefully as heretofore, since, when the permeation process reaches a gland, emboli may be formed which carry on the disease to more distant glands. In Mr. Handley's words, therefore, "the object of the operation should be the removal of the permeated area of the lymph-vascular system which surrounds the primary growth, and of the lymphatic glands which may have been embolically invaded along the trunk lymphatics of the area concerned" (p. 178). He details not merely the principles governing the operation, but gives all the steps clearly enough to guide the surgeon.

In an appendix, the author discusses lymphatic permeation in the spread of melanotic sarcoma.

Mr. Handley's work comes from the Middlesex Hospital Cancer Research Laboratories, and would be, even if it stood alone, sufficient justification for their existence. No one, however crusted he may be in tradition, can read the volume without seeing that, whether accepted in every detail or not, Mr. Handley's researches and conclusions cannot be overlooked. Most readers will come away convinced that a great step forward has been made in our knowledge of an important branch of pathology. What Mr. Handley has done for cancer of the breast must be done by himself or by others for cancer of other regions, and we are glad to learn that he is at present investigating the problem as it concerns the stomach.

In the presence of so much important material, it is hardly worth mentioning that the style of the author is excellent, and that his argument is both clear and concise. The general form of the book, as is usual with Mr. Murray's house, is all that can be wished.

Mr. Charles Cathcart's book (*b*) comes as a useful protest against the current fashion of treating of the "cancer problem" as a thing apart from the general problem of tumour formation. Such isolation of part of a question can only lead to confusion and wasted labour, and although the distinction between "innocent" and "malignant" is of great importance both clinically and pathologically, yet it is never absolute, and there is a wide debatable land between the two territories. Mr. Cathcart arranges his arguments in three battalions which reinforce each other in attack. First, he shows by description of several series of tumours, the easy gradation from the obviously innocent to the obviously malignant. Next, he details instances of the transformation of innocent into malignant growths. Finally, he gives examples of tumours presenting various combinations of innocency and malignancy. Mr. Cathcart's series are illustrated by excellent photographs of gross specimens, but he does not supply the series of microscopic sections which would prove equally instructive. There is nothing particularly novel in the ideas presented, but the book will be of service in emphasising the essential unity of the tumour problem.

Mr. Bland-Sutton's book on Tumours is so well known to the profession that the appearance of a new edition (*c*) hardly calls for prolonged notice. The special features of Mr. Bland-Sutton's book have always been its comprehensiveness and its elucidation of the subject by the aid of comparative pathology; while it had the added interest that it vigorously expressed the views of a teacher of marked originality and wide experience. These features it possesses still, the last mentioned perhaps to an extent hardly satisfying to the demands of the logic of science. Dogmatic statements abound where tentative opinions would have been more fitting. For example, the discussion of carcinoma of the ovary (p. 515) opens with the statement, "Primary cancer of the ovary is a rare disease, and one concerning which we know little." In the bibliography at the end of the chapter only one reference is given to any work on cancer of the ovary more recent than 1902; if Mr. Bland-Sutton had consulted more recent literature he would have found that in the practice of other surgeons the disease is by no means rare. The present reviewer has had submitted to him for pathological examination no less than three cases within a fortnight. On p. 61, we meet the extraordinary statement that "Myomata, or tumours composed of unstriped muscle fibre, are very rare," although the author immediately quotes the uterus as one of the sites for them. We have been unable to detect the difference between the myeloma or myeloid sarcoma, described in chapter iv., and the sarcoma of bones, in chapter vii; both microscopically and macroscopically they appear from the description to be indistinguishable. It is an ungrateful task finding fault with an old friend such as this book, but it is just because the book is regarded as an authority that we are constrained to point out that the pathological sections have not been sufficiently revised or brought up to our modern knowledge. In regard to treatment, Mr. Bland Sutton is a more trustworthy guide.

Those who are interested in Poor-law reform will be interested to learn that a fund is being collected to present a suitable testimonial to Dr. Milson Rhodes. The movement was started at Didsbury, Dr. Rhodes' own district, and close to the Chorlton Union, with which his name is so closely associated. It will be remembered that he was one of the founders of the Association of Poor-law Union. A considerable sum of money has been already subscribed, and the Editor of the *Poor-law Officers' Journal*, Whitefriars Street, London, E.C., will be pleased to receive any further contributions to the fund.

(*b*) "The Essential Similarity of Innocent and Malignant Tumours: A Study of Tumour Growth." By Charles W. Cathcart, M.A., M.B., C.M. Edin.)., F.R.C.S. (Eng. and Edin.). Illustrated. Bristol: John Wright and Co. Pp. xii and 79. Price 9s. 6d. net.

(*c*) "Tumours, Innocent and Malignant, their Clinical Characters and Appropriate Treatment." By J. Bland-Sutton, F.R.C.S. Fourth edition. With 355 engravings. London: Cassell and Co. 1906. Pp. xii and 675. Price 21s.

Weekly Summary of Medical Literature, English and Foreign.

Specially compiled for The Medical Press and Circular.

RECENT GYNÆCOLOGICAL AND OBSTETRICAL LITERATURE.

Relation of Ovarian Cysts to Abdominal and Pelvic Pain.—Sampson (*Surg. Gynæcol. and Obstetrics*, June, 1907).—The sensibility of the walls of eight large ovarian cysts was studied and all were found to be insensitive to touch and pain. Traction on the pedicles caused pain which became greater as the traction was increased. The pain was usually at first localised in the side of the abdomen at or about the pelvic brim but as the traction was increased it became more diffuse. When diffuse it was felt over the entire side of the abdomen or in the back, and as soon as the pedicles were released the patients were immediately relieved. His observations on the sensibility of the normal tube, ovary, and uterus do not entirely accord with those of Linnander, who thinks that they are insensitive, for while finding them so in some cases when pinched with a mouse tooth forceps. Yet in a number pinching these structures caused pain. Again intraperitoneal pelvic operations have been found by the writer to be less painful in women past the menopause, and the instances of apparently sensitive ovaries, tubes, and uteri have occurred in younger women, but even here the apparent sensibility to pain has been inconstant, and when present it has always been much less than that of the parietal peritoneum, and the ovary has seemed the least sensitive of the three. In all cases the parietal peritoneum was found to be *very sensitive*, and especially to traction The omentum and intestines were found to be insensitive to pinching. He sums up as follows: The presence of abdominal or pelvic pain in patients with ovarian cysts usually indicates either secondary changes in the cyst involving some sensitive near-by structure or the presence of some other condition, independent of the cyst, which may cause pain. The principal causes of pain from ovarian cysts are traction or twisting of the pedicles or the traction of the parietal peritoneum from adhesion. F.

Ectopic Gestation with special reference to the Treatment of Tubal Rupture.—Robb (*Amer. Jour. Obst. and Gynæcol*).—The writer quotes the opinions of recognised authorities and then concludes his paper with the following account of the method adopted by him for tubal rupture during the past four years. If there are signs of improvement in the patient's condition (and this in his experience always takes place) he keeps the patient under further observation. The change for the better is brought about by carefully stimulating the patient by means of saline infusions under the breasts, and in some instances also by means of hot saline enemata. If the patient is not vomiting or not nauseated, a stimulant in small quantities is administered by the mouth. In addition morphia is given hypodermically for the pain and nervousness. External heat is applied to the body and the lower end of the bed is slightly elevated. Sulphate of strychnine is also given hypodermically in doses of 1-10 to 1-20 of a grain every half hour or so, according to the indications. While this treatment is being carried out, the operating room is prepared, so that it can be used at a moment's notice. This treatment is also carried out at the patient's homes. Then as soon as the woman had recovered from the shock of the rupture she was transported to the hospital, where an operation could be carried out at any time that the necessity might arise. Every patient in the series of twenty had gradually improved, so that after two or three days, and in some instances after twelve day's time, the operative procedures have been carried out with very little, if any, shock to the patient. The writer is not prepared to state dogmatically that women do not bleed to death from hæmorrhage following ruptured tubal pregnancies, but he is of the firm conviction that surgeons are losing many of their desperate cases from over-haste in operating upon them. F.

Valvular Disease of the Heart in Pregnancy and Labour.—Newell (*Sur. Gynæcol. and Obst.*, May, 1907). Any organic heart lesion, even if perfectly compensated under normal conditions of life, should arouse apprehension and call for constant watchfulness if pregnancy supervenes. In case pregnancy comes as a complication when the heart lesion is imperfectly compensated, the indication is for immediate relief by emptying the uterus, since a heart which is not able to care for its ordinary work has no chance of supporting the added burden of pregnancy. When a previously well compensated heart fails under the extra work thrown on it by pregnancy an attempt may be made to restore compensation by test and appropriate treatment, but unless the measures are promptly successful the heart must be relieved by the removal of the extra burden. In any case in which an organic heart lesion can be demonstrated, even though it may have caused no symptoms during pregnancy, labour should be regarded with apprehension, and every means should be taken to shorten the strain of labour and thus relieve the heart of its extra burden, although it may seem to be doing its work satisfactorily. F.

Hyperemesis gravidarum and its relation to eclampsia.—Skorbanski (*Zentralbl. fur Gyn*, Nr. 27 1907). Four hypotheses exist concerning the ætiology of Hyperemesis gravidarum: (1) The hypothesis of the simple reflex from the uterus to the stomach; (2) The auto-intoxication hypothesis which declares that the hyperemesis is the result of intoxication of the body by toxines which arise in the intestine, in the stomach, in the liver, or in other organs; (3) That it is hysterical in origin; (4) That the intoxication of the organism arises from poisons which develop in the ovum. In the author's opinion the last hypothesis best explains the different cases of hyperemesis; it also explains the relationship between hyperemesis and eclampsia. Hyperemesis in the first half of pregnancy can arise as a result of the immunisation of the organism by an antitoxin produced from products of the disappearing villi. This antitoxin is necessary for the organism at the end of pregnancy, when large masses of toxines arise. When immunisation at the beginning of pregnancy is successful, the organism easily overcomes these poisons at the end of pregnancy, but when it is unsuccessful eclampsia is observed. Thus eclampsia most frequently assails healthy women who felt perfectly well during their pregnancy. Some cases of eclampsia which came under the author's observation in Prof. Rein's klinik in St. Petersburg strengthen the author's belief in this hypothesis, the first half of pregnancy gave them no trouble. There are, however, eclamptic patients who suffered during the first half of their pregnancies from severe hyperemesis; one must conclude that in these cases in spite of the poisoning of the organism during the first half of pregnancy a sufficient amount of immunisation material was not produced. In conclusion the author describes a case of hyperemesis for which abortion had to be induced. G.

The Corpus Luteum.—Fellner (*Med. Klinik*, 1906, Nr. 42) reviews all the latest investigations and opinions concerning the corpus luteum and its internal secretion. The difference has long since disappeared, which was formerly made between the corpus luteum of menstruation and that of pregnancy. While Sobotta considers that the lutein cells arise from the granulosa cells a not inconsiderable number of authors adhere to the investigation of Stoeckel, who sought to prove their origin from the theca cells. Numerous investigations have been made concerning the cystic changes in the corpus luteum, which by the presence of blood one can generally distinguish from cysts of the Graafian follicles. Hæmorrhages into the interior of the cysts can be very dangerous, even fatal. According to Stoeckel multiple cysts depend on an abnormally fast rate of ripening of the follicles and corpus luteum formation, which passes off without opening of the follicle and thus leads to cyst formation. The investigations concerning the simultaneous appearance of ovarian changes on the one hand and hydatidiform mole and syncytioma on the other have excited especial interest. All the properties which were formerly entirely attributed to the ovary are attributed now by Fraenkel, on the ground of numerous experiments, to the corpus luteum alone. Although we do not yet know anything certain concerning the function of the corpus luteum, we must conclude that the corpus luteum is a gland with an internal secretion. G.

Prolonged Pregnancy.—Bossi (*Zentralbl. fur Gyn.*, No. 27, 1907) regards pregnancy as prolonged when it exceeds the term of 285 days, without any symptoms of labour. Such a condition exists among 2—3 per cent. of all pregnant women, and may cause severe complications during delivery. The characteristics of the ovum are as follows: (1) Unusual length of the fœtus; (2) the bones of the head are larger and more ossified; (3) a well marked disproportion between the length, ossification, and the size of the head bones and the weight, which is usually less than is expected. The author fully describes some cases out of the fifty-two observed by him in order to illustrate the difficulties which often arise. The frequency of uterine inertia is remarkable. Bossi is inclined to refer this to the fatty degeneration which the muscle fibres undergo when gestation exceeds its normal length. The treatment indicated is artificial induction of labour, and pubiotomy when the head is so ossified and hard that even with Walcher's position safe delivery is uncertain. G.

Hæmorrhages at the Beginning of Puberty.—Fischer (*Monatssch. für Geb. und Gyn.*, Bd. XXV., Hft. 4) records the case of a girl, æt. 12, who for two years had suffered from practically continuous hæmorrhage from her gums. She was extremely anæmic. She bled very severely during her first menstruation. Examination revealed a normal condition of the genitals. Ergot, adrenalin, vaginal plugging, and even plugging of the uterus with perchloride of iron wadding and tannin gauze were of no avail. Finally she was curetted, and this was successful. The endometrium removed proved to be normal, but rather poor in glands. A second case, a girl, æt. 14, had bled uninterruptedly for six weeks. She was very anæmic, the quantity of hæmoglobin in the blood being 10 per cent. On the trunk and on the extremities there were little points of hæmorrhage. Curettage stopped the bleeding, but did not give sufficient material for microscopical examination. Eight days afterwards she died from profuse nasal epistaxis. The first case was one of hæmophilia, the second of purpura hæmorrhagica. There have been several cases of hæmophilia in women recorded lately. As regards the second case, uterine hæmorrhages have been observed complicating purpura hæmorrhagica. In conclusion, the author discusses a series of eleven cases in which severe hæmorrhage was associated with the first menstruation. G.

High Forceps.—Riemann (*Monatssch. für Geb. und Gyn.*, Bd. XXV., Hft. 4) reports the results obtained with high forceps in the Breslau school for midwives. In his opinion they are not so dangerous for the mother and child that they should be rejected generally, especially in cases of contracted pelvis. The fœtal mortality was 22 per cent.; maternal injuries, 7 per cent.; fœtal injuries, 10 per cent.; and the puerperium was prolonged in 16 per cent. of the cases. All this proves that high forceps should not be employed without the strongest indications—*i.e.*, danger for either the mother or child. The best results are obtained when the head is well moulded and the child in good condition; that is when the forceps are indicated for the mother's sake. In such cases it is possible to deliver relatively large uninjured infants, when the conj. diam. measures from 8-8¾. The usefulness of the high forceps diminishes as the contraction of the pelvis increases. G.

Ovariotomy during Pregnancy, Labour, and the Puerperium.—Retzlaff (*Monatssch. für Geb. und Gyn.*, Bd. XXV., Hft. 4).—In the first case a IV.-para., æt. 35. During bimanual examination a tense and elastic tumour was found in Douglas's pouch, which laparotomy showed to be a parovarian cyst the size of an apple, with its pedicle twisted, lying behind the pregnant uterus. In a second case the uterus was enlarged to the size of three months' pregnancy and retroflexed; on top of it was a cystic tumour the size of a child's head. The laparotomy revealed a dermoid of the right ovary. Operation did not interrupt the pregnancy in either case. In a third case the uterus, slightly enlarged, was pressed against the symphysis by a tumour in Douglas. A dermoid cyst was removed by colpo-cœliotomy. The pregnancy went to full term. The author now discusses the combination of pregnancy and ovarian tumour, and says that it is difficult to declare which is the best procedure to adopt regarding operation. One must consider the period of the pregnancy, the size and nature of the tumour, its position, and the condition of the other ovary. It is more unfavourable when the tumour does not reveal itself during pregnancy, but is first discovered at the beginning of labour, when it may prolong the expulsion of the ovum or perhaps render it impossible. As examples the author describes two cases. If the ovarian tumour is diagnosed intra partum, and it is an obstruction to labour, an effort may be made to replace it either from the vagina or rectum with an anæsthetic if necessary, so that the labour may proceed as naturally as possible. If it is impossible to replace it, an ovariotomy must be performed. The puerperium can also be complicated in a most unpleasant manner by ovarian tumours. It seems as if the long-continued compression and crushing produced by difficult deliveries so very much lowers the vitality of the tumour tissues that they afford an especially favourable breeding-ground for the development of infection spreading upwards from the genital tract. G.

Appendicitis and Pregnancy.—Puech (*Provence Med.*, 1906, Nr. 52) reports two cases. In the first, appendicitis developed at the seventh month of pregnancy, and was not recognised at the beginning. Three days later the diagnosis was made, and, owing to the severity of the case, an operation decided on. It was not performed, however, as the patient began to improve. Less than 24 hours after this decision the patient died. In a second case a patient six months pregnant was suddenly seized with very severe pains, vomiting, etc. A diagnosis was first made of kidney colic. The author, when summoned, made the correct diagnosis, and as the patient's condition did not improve, he operated. A day and a half later she delivered herself spontaneously of a dead six months' fœtus. The convalescence was uneventful. As a result of these observations the author warmly recommends operation in such cases. G.

Arrangements for the amalgamation of the London Royal National and City Orthopædic Hospitals have now been completed. Dr. Hughlings Jackson has been elected Honorary Consulting Physician to the Royal National Orthopædic Hospital, and Dr. Sutherland, Mr. John Poland, and Mr. J. Jackson Clarke have been elected Honorary Physician and Honorary Surgeons respectively. The new building operations have been begun, and a hospital for 213 in-patients is being built on the site of the old hospital and the adjoining premises.

MEDICAL NEWS IN BRIEF.

Royal College of Surgeons of England.

An ordinary meeting of the council of the Royal College of Surgeons was held on Thursday last, Mr. Henry Morris, president, in the chair. Mr. Louis A. Dunn, F.R.C.S., Surgeon and Lecturer at Guy's Hospital, was elected a member of the court of examiners in the vacancy occasioned by the retirement of Mr. Golding-Bird. Mr. Pearce Gould, F.R.C.S., Surgeon to Middlesex Hospital, and Mr. William B. Paterson, F.R.C.S., Dental Surgeon to St. Bartholomew's Hospital, were re-elected members of the board of examiners in dental surgery.

Upon the recommendation of the committee of management it was decided to add Alleyn's School, Dulwich, to the list of institutions recognised by the examining board for instruction in chemistry and physics. The balance sheet and statement of receipts and expenditure for the past collegiate year, submitted to the council by the Finance Committee, was approved and adopted, and it was decided to publish the statement of receipts and expenditure as usual in the college calendar.

A letter was read from the honorary secretary of the British Dental Association communicating the following resolution adopted at the annual general meeting of the association held at Cardiff on May 18th, 1907: "That any resolution, prescribing 'not less than two years' instruction in mechanical dentistry,' instead of three years as heretofore, is seriously detrimental to the efficiency of the profession." It was decided to refer the same to the court of examiners to consider and report.

The secretary having reported the death of Professor Edward Hallaran Bennett, of Dublin, an Honorary Fellow of the College, the president informed the council that he had conveyed to Mrs. Bennett the sympathy and condolence of the council, and a letter from Mrs. Bennett was read thanking the council for their sympathy in her bereavement.

The Institute of Hygiene.

Lord Robert Cecil held a reception at the Institute on Friday evening last, which was largely attended by members of the medical profession. Both the exhibition and lecture hall were very crowded at times, but the guests found much to interest them in examining the various foods and beverages on exhibition, as well as in the demonstrations of new appliances and machines in the hospital section. Among those who accepted the invitation were:—Dr. Appleby, Dr. Anderson, C.I.E.; Mr. Arthur Barker, Sir William Bennett, K.C.V.O.; Prof. Rose Bradford, M.D.; Mr. Jackson Clarke, F.R.C.S.; Dr. Leigh Canney, Colonel Drake-Brockman, F.R.C.S.; Dr. A. H. Payan Dawnay, Mr. T. J. Faulder, F.R.S.S.; Dr. W. Ewart, Mr. H. A. T. Fairbank, F.R.C.S.; Dr. Clement Godson, Dr. Griffith, Mr. Pearce Gould, F.R.C.S.; Professor Halliburton, M.D.; Sir Constantine Holman, M.D.; Dr. Havilland Hall, Mr. Arbuthnot Lane, F.R.C.S.; Dr. McLeod, Dr. Ogilvie, Mr Openshaw, C.M.G., F.R.C.S.; Dr. Steele-Perkins, Dr. Priestley, Mr. Mayo Robson, F.R.C.S.; Sir William Ramsay, F.R.S.; Dr. Sandwith, Dr. John C. Thresh, Mr. Tubby, F.R.C.S.; Mr. Arch. S. Vasey, F.I.C.; Professor Sims Woodhead, M.D., etc.

Action for Damages by a Medical Man.

At Leeds, on July 27th, before Mr. Justice Ridley and a special jury, was tried the action of "Rhodes v. Lancashire and Yorkshire Railway Company." This was a claim by a Dr. Rhodes, of Manningham near Bradford, for damages for personal injuries sustained in a railway accident at Lowmoor between Halifax and Bradford, on January 7th, 1907. The railway company did not dispute liability, and the issue tried was that of damages only.

The plaintiff stated that in the accident his head was violently thrown against the carriage. He suffered from severe pain in the lumbar region and sciatic nerve; he was unable to walk without great discomfort for a considerable period. He went for electric treatment to a hydropathic establishment at Southport during February; but, as he received very little benefit from this, he ultimately went on a voyage to South Africa. His practice averaged £400 a year, and it had suffered in his absence. He claimed £1,500 damages. The defendants called evidence to show that the plaintiff was much less seriously injured than he represented himself to be. Their medical witnesses were of opinion that the voyage to South Africa was unnecessary, and that the plaintiff not only would have been able to resume practice earlier than he did, but that he would have benefited thereby. It transpired during the course of the case that while the plaintiff was staying at the Southport establishment an official of the company stayed there and watched his movements.

The learned Judge, in summing up, commented strongly on this conduct, and said that in a case where it was clear there had been considerable injury it was very regrettable that the railway company had thought fit to employ a detective to spy on the plaintiff.

The jury awarded the plaintiff £600 damages.

Second International Congress of School Hygiene.

At the request of the King, Lord Crewe, Lord President of the Council, has consented to open the Second International Congress of School Hygiene on the morning of Monday, August 5th. While still adhering to their resolution not to issue official invitations to foreign Governments to send delegates, the Board of Education has arranged with the Foreign Office to take such steps as are likely to remove any misunderstanding which might prevent some foreign delegates from accepting the invitations issued. It is hoped, therefore, that all hindrances to the complete success of the Congress have been removed.

PASS LISTS.

Royal College of Physicians of London.

At the *comitia* of the Royal College of Physicians of London, held on July 25th, the President, Sir R. Douglas Powell, in the chair, the following were elected officers of the college:—Censors, David Ferrier, M.D., J. Mitchell Bruce, M.D., T. Clifford Allbutt, M.D., J. F. Goodhart, M.D.; treasurer, Sir Dyce Duckworth, M.D.; Emeritus registrar, Sir Henry A. Pitman, M.D.; registrar, Edward Liveing; Harveian librarian, J. Frank Payne, M.D.; assistant registrar, Oswald A. Browne, M.D.; Library Committee, Norman Moore, M.D., William Osler, M.D., H. D. Rolleston, M.D., A. Mercier, M.D.; curators of the museum, William Cayley, M.D., W. H. Allchin, M.D., S. J. Sharkey, M.D., and Dr. W. Hunter.

The following, having passed the required examinations, were admitted members of the college:—A. W. Falconer, V. S. Hodson, M.B., B. Hudson, M.A., M.B., L.R.C.P., H. C. C. Mann, M.D.Lond., L.R.C.P.; R. H. Miller, M.D.Lond., L.R.C.P.; H. Pritchard, M.D.Lond., L.R.C.P.; E. A. Ross, M.D.; G. M. Campbell Smith, M.A., M.D.; T. E. Tylecote, M.D. Vict.; S. A. K. Wilson, M.A., M.B., Edin.

The following were elected examiners in the subjects indicated for the ensuing collegiate year:—

First Examination.—Chemistry, J. M. Thomson, F.R.S., G. Senter, Ph.D., B.Sc; physics, Dawson F. D. Turner, M.D., A. W. Porter, B.Sc; materia medica and pharmacy, C. Ogle, M.B., J. J. Perkins, M.B., R. A. Young, M.D., J. P. Stewart, M.D., O. F. F. Grunbaum, M.D.; physiology, W. D. Halliburton, M.D., E. H. Starling, M.D.; anatomy, P. Thompson, M.D.; medicine, J. A. Ormerod, M.D., S. H. C. Martin, M.D., W. Collier, M.D., W. M. Murray, M.D., N. Dalton, M.D., H. D. Rolleston, M.D., Sir E. Cooper Perry, M.D., F. J. Smith, M.D., A. P. Luff, M.D., W. E. Wynter, M.D.; midwifery, J. Phillips, M.D., H. R. Spencer, M.D., W. J. Gow, M.D., T. W. Eden, M.D., G. H. D. Robinson, M.D.; public health, W. H. Wilcox, M.D., A. G. R. Foulerton, F.R.C.S.; Murchison scholarship, S. J. Sharkey, M.D., W. Hale White, M.D.

The Baly gold medal, instituted in 1866 by Dr. F. D. Dyster, of Tenby, "In Memoriam Gulielmi Baly, M.D.," which is awarded every alternate year on the recommendation of the president and council to the person who shall be deemed to have most distinguished himself in the science of physiology, especially during the two years immediately preceding the award, was awarded to Ernest H. Starling, M.D., F.R.C.P., F.R.S., Jodrell Professor of Physiology, University College, London.

Dr. James Ramsay, of York, presented the college with an autotype copy of a portrait of James Atkinson, 1759–1839, author of "Medical Bibliography," Letters A.-B. The thanks of the college were accorded to the donor.

On the recommendation of the committee of management the following institutions, which have been visited by a member of the committee and reported as fulfilling the requirements of the board, were added to the list of institutions recognised by the examining board in England for instruction in chemistry and physics:—The Municipal Technical School, Birmingham; Aldenham School, Elstree; Alleyn's School, Dulwich.

The following gentlemen, having conformed to the by-laws and regulations, and passed the required examinations, had licences to practise physic granted to them at this meeting:—S. H. C. Air, N. G. Allin, M. D. Anklesaira, R. E. Apperly, J. Appleyard, F. W. Aris, H. P. Aubrey, F. J. F. Barrington, R. L. Barwick, J. W. B. Bean, T. H. C. Benians, H. S. Berry, F. A. B. Bett, R. G. Bingham, J. W. Bintcliffe, F. R. Bray, A. Camacho, L. B. Cane, H. B. Carlyll, R. G. Chase, R. N. Chopra, F. Clayton, M. Cohen, F. G. Collins, P. C. Conran, R. N. Coorlawala, J. E. Copland, E. M. Cowell, A. J. Crawford, L. Croft, G. W. M. Custance, H. G. Daft, D. W. Daniels, W. Deane, H. C. Devas, W. C. M. Dickey, A. W. C. Drake, J. Duncan, J. E. Ellcombe, T. Evans, E. G. Foote, C. L. Forde, S. R. Gleed, E. S. Goss, H. Granger, W. B. Griffin, J. Hadwen, A. Hanau, W. W. Hellyer, *O. H. Hensler, T. S. Higgins, J. E. Hodson, G. Holroyde, A. E. Iles, W. A. M. Jack, W. J. Jago, A. G. Jenner, W. F. Jones J. L. Joyce, C. G. Kemp, *F. E. H. Keogh, S. M. Khambata, A. S. Khan, H. J. S. Kimbell, P. J. Kolaporewalla, C. F. L. Leipoldt, J. F. Lessel, J. R. Lloyd, J. J. Louwrens, L. G. J. Mackey, P. W. N. Mathew, J. E. Middlemiss, E. P. Minett, G. N. Montgomery, *E. Morris, H. W. Nicholls, H. Nockolds, F. W. O'Connor, H. P. Orchard, E. V. Oulton, R. C. Paris, J. G. Phillips, B. J. Phillips-Jones, A. H. Pollard, M. A. Rahman, J. Ramsay, A. B. Rooke, V. K. Sadler, *B. Saul, G. H. Sedgwick, G. A. Simmons G. M. Simpson, F. O. Spensley, S. F. St. J. Steadman, R. Y. Stones, E. Sutcliffe, R. S. Townsend, H. T. Treves, J. R. H. Turton, B. Varvill, H. F. Vellacott, W. G. H. M. Verdon, P. J. Verrall, S. Vosper, *F. J. Waldmeier, G. H. Watson, J. N. Watson, R. J. Willan, I. S. Wilson, J. F. Windsor, G. E. Wood, W. H. Woodburn, L. H. Wootton, O. K. Wright. (*Under regulations dated October 1st, 1884.

Royal College of Surgeons of England.

At the meeting of Council, on July 25th, the following candidates received the Diploma of Membership:—Samuel H. C. Air, Norman G. Allin, Manekjie D. Anklesaria, Raymond E. Apperly, James Appleyard, Frederick W. Aris, Harold P. Aubrey, Frederick J. Barrington, Richard T. Barwick, John W. B. Bean, Thomas H. C. Benians, Horace S. Berry, Raymond G. Bingham, John W. Bintcliffe, Frederick D. Bray, Angel Camacho, Leonard B. Cane, Hildred B. Carlyll, Robert G. Chase, Ram N. Chopra, Frank Clayton, Meyer Cohen, Francis G. Collins, Philip C. Conran, Rustom N. Coorlawala, James E. Copland, Ernest M. Cowell, Andrew J. Crawford, Lawrence Croft, Gustavus W. M. Custance, Hedley G. Daft, Davis W. Daniels, William Deane, Horace C. Devas, William C. M. Dickey, Arthur W. C. Drake John Duncan, John E. Ellcome, Trevor Evans, Edmund G. Foote, Cecil T. Forde, Seymour D. Gleed, Edward S. Goss, Henry Granger, Walter B. Griffin, John Hadwen, Alfred Hanau, William W. Hellyer, Oscar H. Hensler, Tom S. Higgins, John E. Hodson, Gerald Holroyde, Arthur E. Iles, William A. M. Jack, William J. Jago, Arthur G. Jenner, William F. Jones, James L. Joyce, Charles G. Kemp, Frederick E. H. Keogh, Sohrab M. Khambata Abdus S. Khan, Henry J. S. Mimbell, Phirozeshaw J. Koloporewalla, Christian F. L. Teipoldt, John F. Lessel, John R. Lloyd, James J. Louwrens, Philip W. Mathew, James E. Middlemiss, Edward P. Minett, Gordon N. Montgomery, Edward Morris, Harry W. Nicholls, Humphrey Nockolds, Francis W. O'Connor, Harry P. Orchard, Ernest V. Oulton, Robert C. Paris, John G. Phillids, Benjamin J. Phillips-Jones, Arthur H. Pollard, Mohamed A. Rahman, Jeffrey Ramsay, Alfred B. Rooke, Vyvyan K. Sadler, Barnett Saul, George H. Sedgwick, George A. Simmons, George M. Simpson, Frank O. Spensley, Sidney F. St. J. Steadman, Robert Y. Stones, Edward Sutcliffe, Reginald S. Townsend, Harold T. Treves, James R. H. Turton, Bernard Vasvill, Harold F. Vellacott, Walter G. H. M. Verdon, Paul J. Verrall, Sydney Vosper, Frederick J. Waldmeier, George H. Watson, John N. Watson, Robert J. Willan, Ivan S. Wilson, James F. Windsor, George E. Wood, William H. Woodburn, Leonard H. Wootton, Oswald K. Wright.

Royal College of Physicians and Surgeons.

The Diploma in Public Health of the Royal Colleges of Physicians and Surgeons was issued to the following candidates:—Isodore M. Bourke, L.R.C.P., M.R.C.S.; Edwin Eckersley, M.B., C.M.Edin.; Robert J. Ewart, F.R.C.S., L.R.C.P., M.D.Vict.; Matthew H. Fell, L.R.C.P., M.R.C.S.; Harry A. Foy, L.M.& S.Bombay, L.R.C.P.& S.Edin., L.F.P.& S.Glas.; Frederick W. Lewis, M.B.Lond.; William G. Liston, M.D., Ch.B. Glas.; Edward D. Parsons, L.R.C.P., M.R.C.S.; Wentworth F. Tyndale, C.M.G., L.R.C.P., M.R.C.S., M.B.Lond.; Brian Watts, L.R.C.P., M.R.C.S., M.D. Bruxelles; Bernard H. Wedd, L.R.C.P., M.R.C.S.; M.D.Lond.; James E. Wilson, M.B., B.Ch., R.U.I., Charles R. Wood, L.R.C.P., M.R.C.S., M.D., B.S. Durh.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow.

The quarterly examinations of the above Board, held in Edinburgh, were concluded on the 22nd inst., with the following results:—

First Examination (four years' course).—Mr. Thomas Kennedy, Belfast, passed the examination.

First Examination (five years' course).—Of 37 candidates entered, the following 17 passed the examination: John Richard Smith, Maneck B. Motafram, Hormusji J. Dadysett, Arthur Saldanha, Robson E. I. Mason, Victor G. L. van Someren, John Ross, Michael P. Power, David A. Evans, William J. H. Davies, Ernest J. Fisher, Andrew Hegarty, James A. Hutchinson, Satis Chandra Das, Harry C. Sutton, Frank D. Johnson, and Gajanan J. Nahimtura; and 6 passed in physics, 9 in biology, and 2 in chemistry.

Second Examination (four years' course).—Of 3 candidates entered the following 2 passed the examination: Michael J. O'Shea, and Richard B. Sephton.

Second Examination (five years' course).—Of 41 candidates entered, the following 18 passed the examination: Ernest B. Keen, John W. Hitchcock (with distinction), Charles B. Robinson, Thomas N. Usher (with distinction), George F. Neill (with distinction), Alfred F. Tughan, Rankin G. Walker (with distinction), Ralph C. Fuller, Robert H. Jones, Harold H. Field-Martell, Andrew D. Turnbull, Robert Massie, MacWilliams Henry, William T. Torrance, Robert M. M. Wilson, Syed Abdul Karim, Bertram Flack, and Isaac J. McDonough; and 4 passed in anatomy and 2 in physiology.

Third Examination (five years' course). Of 30 candidates entered, the following 17 passed the examination: John Young, Baldey Singh, Surendra Kumar Sen, Albert R. H. Harrison, George F. Ford, Thomas J. George, Edith Huffton, Marguerite Alice C. Douglas, Edmund Eccles, William Watson, Claude E. Watts, Francis S. Crean, James Morham, Harold A. Higginson, Lily Holt, Hormusji Jehangir Dadysett, and Gajanan Jinabhai Mahimtura; and 4 passed in materia medica.

Final Examination.—Of 54 candidates entered, the following 17 passed the examination and were admitted

L.R.C.P.E., L.R.C.S.E., and L.F.P. & S.G.: Ernest Fielden Nivin, Dennis Cregan McCabe-Dallas, William Alexander Huston, Lakshmi Narayan Ghosh, Richard Howard La Barte Cummins, Francis Ernest Robert Bartholomeusz, Thomas Richard McKenna, Samuel Jay Aanji Kotak, John Scott Ward, Oliver Carlyle, John Edmund Cox, John Arthur Cadman Tull, William Clegg-Newton, Thomas McClure, Rajanja Robert Williams, David Williamson Anderson, and Thirukamu Sundara Reddy; and 5 passed in medicine and therapeutics, 3 in surgery and surgical anatomy, 8 in midwifery, and 10 in medical jurisprudence.

The Royal University of Ireland.

THE Senate met on Friday, July 26th, at 11.30 o'clock a.m. There were present: The Right Hon. Lord Castletown, of Upper Ossory, C.M.G., Chancellor of the University; Sir Christopher Nixon, Bart., M.D., LL.D., Vice-Chancellor, Rev. William Delany, LL.D., Edward Cuming, M.A., Rev. Thomas Hamilton, D.D., LL.D., John R. Leebody, M.A., D.Sc., Michael F. Cox, M.D., Rev. William Nicholas, D.D., Sir Henry Bellingham, Bart., M.A., Right Hon. Lord Killanin, Sir William Thomson, C.B., M.A., M.D., Bertram C. A. Windle, M.D., D.Sc., F.R.S., Right Rev. Monsignor Mannix, D.D. Sir James C. Meredith, LL.D. and Joseph McGrath, LL.D., Secretaries. Apologies were received from Sir Thomas Moffett, LL.D., D. Litt, Sir John Banks, K.C.B., M.D., LL.D., Right Hon. John Young, M.A., Most Rev. Edward Thomas O'Dwyer, D.D., Bishop of Limerick., Rev. Nathaniel McA. Brown, J. Walton Browne, B.A., M.D., Richard W. Leslie, M.D., M.Ch., Charles E. Martin. The results of the recent examinations were considered and Passes, Honours and Exhibitions were awarded in connection therewith. The following returns, which show the progress of the University, as measured by the number of candidates for the Summer Examinations since 1902, were submitted:—

SUMMER, 1907.

	Entered.	Absent.	Retired.	Deprived.	Rejected.	Passed.
Matriculation ..	1,127	17	6	4	420	680
First Arts	693	10	1	1	253	428
Second Arts	513	9	1	2	123	378
B.A. Degree	179	10	3	–	68	98
First Engineering	39	3	–	–	9	27
Second Engineering	37	–	2	–	18	17
B.E. Degree	17	2	–	–	3	12
First Law	14	4	–	–	2	8
LL.B. Degree ..	6	–	–	–	2	4
LL.D. Degree ..	3	–	–	–	–	3
First Medical ..	93	4	6	–	25	58
Diploma in Public Health	1	–	–	–	1	—
	2,722	59	19	7	924	1,713

Corresponding figures in former years:—

1906 ..	2,515	70	20	6	749	1,670
1905 ..	2,313	71	24	1	732	1,485
1904 ..	2,184	67	19	3	636	1,359
1903 ..	2,012	55	14	3	567	1,473
1902 ..	1,902	55	17	5	589	1,236

It was unanimously agreed to confer the Degree of LL.D. *Honoris Causa* upon Sir Otto Jaffé, Knight, J.P., Belfast, in recognition of his valuable public services, especially in the cause of education; and the Degree of D.Mus. *Honoris Causa* upon Mr. W. H. Grattan-Flood, in consideration of his valuable musical compositions and his contributions to Irish periodic literature.

The following resolution was moved by Sir Christopher Nixon, Bart., Vice-Chancellor of the University, seconded by Rev. Dr. Hamilton, and passed unanimously:—

"That having regard to the injurious impressions produced by the adverse comments on the working of this University as a teaching and examining body, made in the report of the Royal Commission on University Education in Ireland (1903), and in that of the Royal Commission on Trinity College, Dublin, and the University of Dublin (1907), the Senate earnestly desires to bring under the notice of the Government the serious injury to higher education in Ireland which will result from any further postponement of the settlement of a question so vitally bound up with the intellectual and material progress of the country."

And the following were named as a deputation to wait on the Chief Secretary in reference thereto:—Right Hon. Lord Castletown, of Upper Ossory, C.M.G., Sir Christopher Nixon, Bart., M.D., LL.D., Rev. William Delany, LL.D., Rev. Thomas Hamilton, D.D., John R. Leebody, M.A., D.Sc., Alexander Anderson, M.A., LL.D., Right Hon. Lord Killanin, Bertram C. A. Windle, M.D., D.Sc., F.R.S., Right Rev. Monsignor Mannix, D.D.

It was agreed to fix October 22nd, 1907, at 4.30 o'clock p.m. for the next Annual Meeting of Convocation.

A meeting of the University was subsequently held at which the following Degrees were conferred:—Degree of Doctor of Laws, Samuel James Diamond, John Francis Butler Hogan, Charles James MacGarry.

The First Examination in Medicine.—Christopher Barragry, Daniel J. Barrett, John L. Brown, Peter A. Clearkin, Maurice J. Cogan, Ernest Colgan, Patrick J. Corcoran, John F. Craig, Thomas P. Davy, Joseph C. Denvir, Bernard Doyle, B.A., Gerald Fitzgerald, Thomas F. S. Fulton, Michael J. Gallagher, Joseph Gorman, M.A., Thomas D. Graham, Gerald S. Harvey, James Hill, Joseph O. Hodnett, Norman L. Joynt, Francis J. Keane, James J. Keirans, John L. Kilbride, James Lafferty, Hugh T. S. M'Clintock, Robert J. M'Connell, Laurence J. J. M'Grath, Michael M'Guire, Aloysius D. MacMahon, Robert C. M'Millan, Daniel M'Sparron, Cornelius Martin, William Megaw, William M. Millar, Alexander G. Mitchell, John J. H. Mitchell, Henry H. Mulholland, Henry J. V. Mullane, Daniel O'Brien, John P. O'Brien, James O'Connor, Thomas F. O'Donoghue, William M. O'Farrell, Joseph A. O'Flynn, Patrick J. O'Grady, Oriel J. O. O'Hanlon, Hugh O'Neill, Joseph Patrick, Joseph Porter, Joseph H. Porter, James M. Rishworth, Walter N. Rishworth, Maurice J. Roche, John M. Rowe, Hugh A. Skillen, Thomas Smyth, Francis J. D. Twigg, William Wilson.

Honours in Botany, First Class.—James J. Keirans, Ernest J. Colgan, Joseph H. Porter.

Second Class.—Michael M'Guire, John J. H. Mitchell, Joseph O. Hodnett.

Honours in Zoology, First Class.—Ernest J. Colgan, James J. Keirans.

Second Class.—John J. H. Mitchell.

Honours in Chemistry, First Class.—None.

Second Class.—James J. Keirans.

Honours in Experimental Physics, First Class.—Joseph O. Hodnett.

Second Class.—Aloysius D. MacMahon, James J. Keirans, Ernest J. Colgan, Hugh O'Neill.

Exhibitions.—First Class, £20.—James J. Keirans.

Second Class, £10.— Joseph O. Hodnett.

Diploma in Public Health Examinations.—Part I.—Stephen B. Walsh, M.B., B.Ch., B.A.O.

London School of Tropical Medicine.

THE following candidates have passed the examinations from May to July, 1907:—

With Distinction.—Captain F. H. G. Hutchinson, I.M.S., M.B., C.M. (Edin.), 1892, D.P.H. Camb., 1907; Captain W. S. Willmore, I.M.S., M.R.C.S., L.R.C.P., 1895; Captain J. N. Walker, I.M.S., M.R.C.S., L.R.C.P., 1897; A. W. Balch, Surgeon U.S. Navy, Ph.G. (Mass.) 1894, M.D. Harvard, 1898; C. A. Godson, I.M.S., M.R.C.S., L.R.C.P., 1904; F. Grenier (Colonial Service), M.B., C.M. (Edin.), 1891.

Ordinary Pass.—T. R. Beale Browne (Colonial Service), M.R.C.S., L.R.C.P., 1901; J. C. C. Ford (Colonial Service), L.R.C.P. and S., L.F.P. and S. (Glas.), 1900; G. Wilkinson, M.B., B.C. (Camb.), T.S.A., 1892; E. Weatherhead, M.B. (Camb.), 1903, M.R.C.S., L.R.C.P., 1903 (Colonial Service),

NOTICES TO CORRESPONDENTS, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessary for publication but as evidence of identity.

Civil Surgeon.—The last tabulated figures available that give the incidence of enteric fever in the army in South Africa are those for 1905. The average strength of European troops in South Africa for the year was 18,593 warrant officers, non-commissioned officers and men. Among this number there were 231 admissions for enteric fever, 17 deaths and a "constant sickness" of 43.60. The rate of admission was 12.4, the mortality .91. and that of "constantly sick" 2.35 per 1,000. These figures showed a marked decrease from 1904, for then the figures were admissions 29.5, deaths 3.79, and average "constantly sick" 6.21. There is even a greater decrease when these figures are compared with average for the three years immediately following the war, namely, 1902-1904. This average showed a decrease of admissions 16.5, deaths 2.48, and average "constantly sick" 3.35. The enteric fever in the army in South Africa last year, as a matter of fact, was less frequent and less fatal even than influenza, for that disease caused 622 admissions and 25 deaths.

Inquirens.—The whole subject is fully explained in Dr. Shaw-Mackenzie's book "On the Nature and Treatment of Cancer" (fourth edition), published by Messrs. Bailliere, Tindall and Cox.

Optician.—We cannot publish our correspondent's letter, inasmuch as the complaints made do not appear to be well founded.

Dr. A. B. J. is thanked for his communication; we will look into the matter, and give our opinion thereon in a private letter.

Dr. J. O. C. will find his communication referred to in another column.

Legend.—Our correspondent is thanked for his enclosure, which, however, is scarcely suitable for this journal.

F. A. B. (Liverpool).—Dr. Munro's "Manual of Medicine," a second edition of which has recently appeared, would answer your requirements exactly.

L. F. P. S.—We know of no official figures to show that trachoma is actually increasing in the East End of London. The disease is certainly an alien one, and should be guarded against by the inspectors at ports, and we know that immigrants are rejected on this score. The newspapers are breaking out into alarmist articles on the subject, but we have not yet seen evidence to show that there is more ground for alarm than there has been for some years past.

THE TREATMENT OF HAIRY MOLES.

Iota writes: In reply to "Query's" question about the treatment of moles, he may find painting the pigmented areas with ethylate of sodium effective. If carefully applied a scab forms on the area, which peels off without leaving much scar. Electrolysis will remove small moles and the hair-bulbs of hairy moles. Rontgen rays are disappointing.

From the "Gentlewoman."—A well-known physician (I can vouch for the truth of the story) was called out late one night to see a child. After entering into the minutest details with regard to the necessary poulticing and nursing, the doctor explained his intention of calling early the following morning. "Call, and will yer?" retorted the mother, arms akimbo, "and yer don't think our Willie's ill enough for medicine, that yer don't! By gad, yer can go, for I'll have a man that 'can doctor.'"

Vacancies.

Metropolitan Asylums Board.—Assistant Medical Officers. Salary, £180 per annum, with board, lodging, and washing. Applications to The Clerk, Metropolitan Asylums Board, Embankment, London, E.C.

Devon County Asylum.—Assistant Medical Officer. Salary, £140 per annum, with board, apartments, and laundry. Applications to the Medical Superintendent, Exminster.

Zanzibar Government.—Bacteriologist. Salary, £300 a year, with free quarters, etc. Applications to Mr. A. W. Clarke, Foreign Office.

County Asylum, Mickleover, Derby.—Junior Assistant Medical Officer. Salary, £120 per annum, with furnished apartments, board, washing, and attendance. Applications to Dr. Legge.

Newport and Monmouthshire Hospital—Secretary and Superintendent. Salary, £200 per annum. Applications to the Chairman, Newport and Mon. Hospital, Newport, Mon.

Royal Lancaster Infirmary.—House Surgeon. Salary, £100 per annum, with residence, board, attendance, and washing. Applications to the Secretary.

Stockport Infirmary.—House Surgeon. Salary, £100 per annum, with board, washing, and residence. Applications to the Secretary.

Whitehaven and West Cumberland Infirmary.—Resident House Surgeon. Salary, £120 a year, with board and lodging. Applications to Wm. H. Sands, Secretary.

Loughborough and District General Hospital and Dispensary.—Resident House Surgeon. Salary, £100 a year, with furnished rooms, attendance, board, and washing. Applications to Thos. J. Webb, Secretary.

Taunton and Somerset Hospital.—House Surgeon. Salary, £100 per annum, with board, lodging, and laundry. Applications to Reginald A. Goodman, Secretary, Hammet Street, Taunton.

Liverpool Royal Southern Hospital.—Resident Pathologist and Registrar. Salary, £100 per annum, with board and residence. Applications to the Superintendent.

Staffordshire County Asylum at Stafford.—Assistant Medical Officer. Salary, £150 per annum, with furnished apartments, board, and washing. Applications to the Medical Superintendent.

Plaistow Fever Hospital, London.—Second Assistant Medical Officer. Salary, £100 per annum, with board, etc. Applications to the Medical Superintendent, Plaistow Hospital, London, E.

The Cambridgeshire, etc., Asylum.—Second Assistant Medical Officer. Salary, £120 per annum, with board, lodging, and attendance in the Asylum. Applications to T. Musgrave Francis, Clerk to the Visitors, 18 Emmanuel Street, Cambridge.

Appointments.

Boycott, A. E., M.D., B.S.Oxon., Gordon Lecturer on Pathology at Guy's Hospital.

Collie, R. J., M.D., C.M.Aberd., a Medical Referee under the Workmen's Compensation Act, 1906, to be attached to County Court Circuit No. 43.

Cope, V. Zachary, M.D., B.S.Lond., Resident Medical Officer at the British Lying-in Hospital.

Kerr, Harold, M.D., Ch.B.Edin., D.P.H.Camb., Assistant Medical Officer of Health of the City of Newcastle-upon-Tyne.

Jones, Richard, M.B., M.S.Edin., D.P.H.Camb., Medical Referee under the Compensation Act for the County Court Circuit of Blaenau Festiniog and Portmadoc.

Leslie, W. Murray, M.D., M.S.Edin., Medical Referee under the Workmen's Compensation Act in the City of London.

MacMyn, J., M.D., M.S.Edin., Certifying Surgeon under the Factory and Workshop Act for the Kirkcudbright District of the county of Kirkcudbright.

Paul, V. G. J., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Act for the Harwich District of the county of Essex.

Pearse, T. F., M.D.Brux., F.R.C.S.Eng., M.R.C.P.Lond., D.P.H., Health Officer to the Corporation of Calcutta.

Births.

Dru Drury.—On July 23rd, at Grahamstown, Cape Colony, the wife of Edward Guy Dru Drury, M.D., B.S.Lond., of a son.

Rowe.—On July 21st, at 260 Woodborough Road, Nottingham, the wife of W. T. Rowe, M.D., B.S.Lond., of a daughter.

Marriages.

Archibald—Riddle.—On July 25th, at Holy Trinity, Upper Tooting, Richard James Archibald, M.R.C.S., L.R.C.P., of Wandsworth Common, London, and Ramsgate, to Gertrude Florence, eldest daughter of F. H. Brimble-Riddle, of Upper Tooting.

Collingridge—Klein.—On July 24th, at St. Stephen's, East Twickenham, William Rex Collingridge, M.R.C.S., L.R.C.P., of Morland, Penrith, elder son of Dr. and Mrs. Collingridge, to Sybil Florence, elder daughter of Dr. and Mrs. E. Klein.

Juler—Chamberlayne.—On July 25th, at St. Peter's, Witherley, Frank Anderson, eldest son of H. Juler, Esq., F.R.C.S., of 23, Cavendish Square, London, to Mabel Alicia, eldest daughter of S. B. H. Chamberlayne, Esq., of Witherley Hall, Atherstone.

Langley—Ryder.—On July 27th, at St. Peter's Church, Dulwich Common, George Johnson Langley, M.D.Lon., eldest son of George R. Langley, of Camberwell Green, to Mabel Rose, daughter of the late Walter Greenway Ryder, and of Mrs. Ryder, of Dulwich.

Murray—Bott.—On July 24th, at St. John's, Paddington, Kenneth G. V. Murray, P.W.D., Egypt, youngest son of Surg.-Lt. Col. John Murray, A.M.S. (retired), of 12, Astwood Road, London, to Muriel H. H. Bott, daughter of the late John Bott and Mrs. Bott, formerly of Cheltenham.

Deaths.

Fowler.—On July 20th, at East Suffolk Hospital, Ipswich, Charles Breame, M.R.C.S., L.R.C.P., son of the late Lieut.-Colonel B. W. Fowler, R.A.M.C., and of Mrs. Fowler, of Bedford.

Moor.—On July 24th, at Branscombe, Guildford, Sarah, widow of late W. H. Moor, M.D., aged 68.

Watson.—On June 15th, at his residence, in Queenstown, Cape Colony, Alexander Lawrie Watson, M.A., M.B., Ch.B., son of George Watson, Esq., Alloway Park, Ayr.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXV. WEDNESDAY, AUG. 7, 1907. No. 6

NOTES AND COMMENTS.

School Hygiene Congress.

THE assembly in London of the Second International Congress on School Hygiene is an event of no little importance, for it marks in some degree the fact that the British people who are credited with being possessed of a business-like faculty, consider that it is worth their while finding out something about this new science. Mr. MacKenna has given out that many of the decisions of the Board of Education are being reserved till he has ascertained the views and experience of the medical educationalists attending the Congress, and for this peculiarly backward Board to have grasped that school hygiene is not a mere fad for the delectation of doctrinaires and busy old maids, but a practical science on the development and application of which much of the future of the country depends, is a sign of hope for the rising generation or, at any rate, for the next rising generation but one. Moreover on the various Committees of the Congress are to be found many excellent people who already recognize that though school hygiene has none of the glamour of politics nor the advertising advantages of philanthropy—as frequently practised—yet that it is in itself an object, and a worthy one, of patriotism. And perhaps most significant of all is the willingness of hard-headed business men who have no immediate concern with the public health as usually understood, to give large sums to the expenses of the Congress, in order that the industrial and commercial prosperity of the country may be maintained, and their own profits thereby kept up. Assuredly then, when science, philanthropy, and commerce are found coquetting under the bland ægis of the Government, we may feel that the birth-right of a fair healthy start in life is likely at some time to become the possession of the proverbial happy English child.

The Municipalised Medical Man—

IT is curious as showing the tendency of the public thought at the moment to notice which of the papers read at the British Medical Association meeting at Exeter is most extensively noticed and commented on in the general press. Apart from the President's excellent address, this honour seems to have been accorded to Dr. Arthur Newsholme's communication to the State Medicine Section, in which he spoke of the whole trend of things at the present time being towards the establishment of a municipal medical service. That undoubtedly is true, and it is a part of the municipalisation of many industries which has been going on so rapidly of late years to the alarm of the financiers, and to the comfort of the poor and lower middle classes, whose necessities were frequently exploited without compunction. But it is a far cry from the municipalisation of water and gas to the municipalisation of the medical attendant, and though for attendance on the poor such an official may eventually develope out of the friendly society and club doctor of to-day, it is not in human nature as at present constituted to take the doctor that is forced on you by the State when you can afford to pay for one of your own choice. Dr. Newsholme thinks that the increasing number of cases treated in voluntary and rate-aided institutions is only a phase in a movement which will end in the proper treatment of all diseases at the expense of the community; and indeed the municipal fever hospital, which was originally founded as a preventive measure, is now used in some towns for the treatment of consumptives, and the isolation hospital itself, which was originally designed for paupers is now universally used for all classes, generally without fee.

And the Municipal Hospital.

BUT, however much the municipal, communal, or socialistic solution might relieve the problem of medical attendance on the poor of its worst features, such a system would necessarily connote the annexation of the hospitals as well, and it certainly is a question whether the people generally are sufficiently educated yet to run a hospital with all its varying interests. Naturally, they would insist, and rightly insist, on the treatment of the patient being the first consideration, but they would be exceedingly apt to overlook the educative and scientific functions of a hospital. The facilities for both these purposes at the present moment in all popularly governed medical institutions, if the pathological departments of some of the asylums be excepted, are either very poor or nonexistent, and unless democracy were much better instructed in the value of pure learning than it is now, there would be great danger of its overlooking the value to humanity of the clinical laboratory, pathological research, and the criticism of students.

A "Return" Case and its Result.

As an example of the incapacity of people to comprehend the unfortunate limitations of medical practice, we may instance the chronic troubles that rage about fever hospitals and "return" cases. At the present moment a wordy warfare is raging at Wolverhampton, on account of one of these unlucky events. One of the magistrates in that town, Mr. C. Marston, is, in what he considers the public interest, vigorously championing the case of one of his employees who with his son caught scarlet fever from a child discharged from the municipal fever hospital. The discharged patient had been detained six weeks in hospital and seems to have undergone the usual preparation prior to leaving the institution. He, however, developed nasal discharge shortly afterwards and infected his father and brother with the disease. Such unfortunate mishaps are so common that all instructed persons have learned to regard them as normal and unavoidable features of fever hospital administration, but to the lay mind they present the elements of unpleasant surprise and the conviction that there must have been want of proper care and supervision. Consequently columns of the local paper are occupied with polite recriminations between the Mayor, the Medical Officer, and Mr. Marston, and public sympathy seems to be on the side of the non-official. Such occurrences would be multiplied a thousandfold were all hospitals and medical services municipalised.

Death of William Rae.

Last week William Rae, the "bloodless surgeon," died at the age of 67. It is only two years since he sprang into fame in the curious line he selected for himself, and since the boom of the summer of 1905, which converted his village of Blantyre into the "Lanarkshire Lourdes," very little has been heard of him and his doings. It is due to him, however, to say that a large number of floral offerings were sent to his funeral by "grateful patients," although it seems from the accounts that an almost equally large number of people were disappointed at his death because they were still "awaiting cure." We may at least charitably suppose that Rae himself believed in his own powers, and that he became intoxicated with the credulity and enthusiasm of his clients, but it sounds rather curious to learn that "Rae's practice, it is believed, will be taken up by his son, a sturdy dairyman, who has shown some of his father's genius." As a matter of fact the force of personality is never better shown than by the break down of the "systems" of quacks as soon as the originator passes away. We venture to predict but little success for the "sturdy dairyman" unless he indeed possesses the "genius" of the miner surgeon, his father.

LEADING ARTICLES.

ACCURACY OF THOUGHT IN MEDICINE.

The address in medicine at the Exeter meeting of the British Medical Association was entitled "A Plea for Accuracy of Thought in Medicine." The fact that it was delivered by Dr. Hale White is sufficient guarantee of a wise and masterly treatment. At first sight it would appear that to plead for greater accuracy of thought in medicine would be simply to admit that the science in question has not yet reached finality. For in a certain broad sense all progress in science depends strictly upon greater accuracy in estimation, in comparison, and in all other methods whereby adequate knowledge of facts and of the relations of facts is obtainable. Medicine is not an exact science, inasmuch as it has to deal with many as yet imperfectly understood laws and phenomena, and is obliged to trust to many imperfect methods of investigation. So that the medical man has to be as accurate as he can in regard to many things and to adopt as a working theory that which appeals to his judgment as being most in conformity with ascertained facts. Dr. Hale White however, shows that medical men often deal intellectually with many things daily before them in a loose and slipshod intellectual fashion. He instances gout, in which we know that urate of sodium is deposited in some cartilages and other structures, and that there is an excess of uric acid in the blood. We speak of gout, bronchitis, neuralgia, sciatica and so on, but where are our proofs in the shape of a sufficient number of accurate *post-mortem* observations? Many obscure symptoms are referred to irregular or suppressed gout, whatever that may mean. Would it not be better to speak out boldly and say we do not know rather than beat the air with nebulous phrases that serve to cloak our ignorance? The candour thus advocated is clearly an attribute of the really scientific mind, but to advise a constant assertion of nescience would be to most medical men a counsel of perfection. It may be doubted whether even a man so secure in professional eminence as Dr. Hale White could carry out that attitude for any length of time in his relations with students, with the medical profession, and with his patients. To inspire confidence is one of the first essentials of practice and the man who lacks a certain amount of dogmatism is apt to be a failure both as a teacher and as a consultant, or as a practitioner, if he be in general practice. Another illustration of inaccurate reasoning was taken from the treatment of chronic osteo-arthritis, which being an affection of the joints more or less resembling gout, is sometimes treated with the restricted diet appropriate for gouty patients. Then we are reminded that peripheral neuritis due to alcohol is wont to attack the anterior tibial nerve in women. We accept the statement of fact and for the rest we calm our intellectual activities into self-satisfied repose with the blessed Mesopotamian word "selection." Yet it is difficult for a medical man who has been pressed into a corner by the cross-examination of "intelligent" patients to offer any truer explanation, because as yet none is known to science. The doubt that may reasonably exist as to the exact state of the cardiac muscle in a given case may in future be to a great extent avoidable by the use of the ortho-diagraph. The introduction of more accurate methods of investigation clearly gives us the data of more accurate thinking, the desirability of which must be evident to all who cultivate science. One point raised by Dr. Hale White is of considerable importance, namely, the way many medical men have of dealing with statistics, often laboriously collected, while they have failed to grasp the fundamental principles of statistical science. When trying to estimate the surgical mortality after operation for impacted gallstone for instance one must remember that impacted gallstone rarely causes death. During 40 years at Guy's Hospital there was only one death in a case not operated on, the total number of deaths from all causes being over 30,000. Mr. Bland-Sutton taking statistics from various London and provincial hospitals finds that out of 35 cases operated upon ten died, or nearly 30 per cent. Before we decide, therefore, that a patient should be advised to seek relief in operation, we have to consider carefully the high mortality that is entailed. Of this address it may be said that in itself it constitutes a valuable and suggestive object lesson in simple, clear and well-balanced reasoning.

CITY METHODS OF PHILANTHROPY.

The great world of medical philanthropy is doubtless working out its salvation by a species of evolution in which the struggle for existence leads to a certain amount of wasteful rivalry and of unfair competition. The hospital funds that have come into existence throughout the Kingdom bid fair sooner or later to establish some sort of reasonable control over the medical charities of which they are primarily the distributing and collecting agents. At present the chief defect of the funds, metropolitan and provincial, lies in the fact that they are not representative, as they should be, of subscribers, of the medical profession, and of the public generally. The result is that small boards of management seek to thrust private fads upon the charities that fall within the scheme of their distribution of grants. To take a recent instance, the Metropolitan Hospital Sunday and the King Edward VII. Funds have insisted upon the amalgamation of the orthopædic hospitals, regardless of the terms of existing charters or constitutions, or the sacrifice of valuable freehold sites. A similar policy of amalgamation, however, is not forced upon the ophthalmic or the throat hospitals, which abound in London and which are surely just as suited for amalgamation as the orthopædic institutions. But what have the Funds to say to the cripples' institutions ? Were there not enough existing already in the Metropolis without the addition of another by Sir William Treloar ? Why should not the great sums he has collected with indomitable vigour have been devoted to the extension and consolidation of pre-existing charities of the kind ? But consistency does not appear to be a guiding principle of the Metropolitan Funds. There can be little doubt that the large amount collected by Sir William Treloar during his year of office has diverted not a few subscriptions from other medical charities, so that in a sense his efforts are open to general criticism. That his aims are noble and his enthusiasm worthy of admiration may be at once admitted, but in the great social world purity of motive is not permitted to put a stop to criticism. Now Sir William Treloar has again and again stated that his institution is the only one in England in which tuberculous diseases of bone in children are subjected to systematic surgical treatment. That assertion has been naturally called into question by those connected with the Liverpool Country Hospital, which was founded ten years ago for that very purpose. A correspondence between the Chairman of the Liverpool Hospital and Sir William Treloar has been published. Notwithstanding that the facts were brought to Sir William's notice first on the 4th of June, and subsequently affirmed again and again, we nevertheless find a letter from the right honourable gentleman was published on July 14th, repeating the statement, which was reiterated at the Queen's Fete. Sir William Treloar, we feel sure, cannot have meant to act ungenerously to any institution, however much he may have been carried away by the ardour and enthusiasm of his own work. For all that the Funds if they are to press forward their amalgamation schemes, will do well to look into the question of the cripples' homes.

CURRENT TOPICS.

Mr. Haffkine and the Indian Government.

We have had on several occasions to draw attention to the treatment meted out by the Government of India to Mr. Haffkine *post* or *propter* the Mulkowal disaster. Whatever they thought or suspected at the time, there is in view of the evidence now before them nothing left for an honourable body of men but to apologise handsomely and unreservedly. In June there was issued, as a Parliamentary paper, the whole of the documents and reports relating to that untoward affair, and those who are acquainted with the value of evidence, especially if they have a working knowledge of bacteriology, will have no hesitation, we apprehend, in completely exonerating Mr. Haffkine from any suspicion of blame. In the *Times*, of July 29th, appeared a letter signed by Professors Ronald Ross, Tanner Hewlett, Albert Grünbaum, W. J. Simpson, Leith, W. R. Smith, Sims Woodhead, Klein, Simon Flexner (of New York), and Hunter Stewart—surely as representative a body of pathologists as could be named—in which the opinion was expressed that "the whole charge against Mr. Haffkine's laboratory has collapsed, the charge being not only not proven, but distinctly disproven." The signatories proceed to point out the petulance of the conduct of the Indian Government in evading this issue, and yet imputing blame to Mr. Haffkine for abandoning the "standard" method of making the prophylactic and substituting a new process "on his own authority." The cynicism of this charge fades away into most delicious impertinence when it is remembered that Mr. Haffkine invented the prophylactic himself, and taught the Indian Government how to manufacture it, and was continually improving it for their benefit. The fact is that the Government have made a hideous error by fastening on the wrong man when wishing to fasten on to somebody; now they have done more, they have acted snarlishly as they felt the ground slipping from under their feet. Is it too late to hope that the officials who now represent the Government will take the manly or honourable course of making what reparation and apology they can to Mr. Haffkine?

Breathing Appliances in Mines.

The Royal Commission on mines, which has been sitting for some time, has presented a preliminary report dealing chiefly with breathing appliances. It is discouraging to find that this country, which depends for its prosperity so largely on mineral wealth, is so far behind other civilised nations that whereas in Austria and France the use of breathing appliances is compulsory, and in Germany their employment is general; yet in Great Britain, except at the Tankersley Collieries in Yorkshire, they seem to be regarded as mere scientific toys. It appears from the report that in Westphalia these appliances have been shown to be so advantageous to the employers in the case of fire and flooding of mines, that they have been universally adopted, and the workers themselves thus, through an indirect channel, get the security they afford. After testing a good many appliances the Commission have come to the conclusion that though there have been great improvements in the latest patterns, no one type is to be recommended for compulsory adoption, but they hope that the mine owners will adopt some one of the best patterns without delay. It is recommended that neighbouring collieries should group themselves into areas having a central rescue station, and that special men should be trained by practice in rescue work to use the appliances. It seems not a little odd that whereas divers have for years been supplied with air while they work under the sea, an invention to preserve the life of workers in foul gases is only just coming to the fore. At any rate it may be hoped that mine owners will not need any further stimulus to adopt this means of protecting and rescuing their workers, now that the Royal Commission has shown its practicability.

Medical Arrangements on American Liners.

At this time of year the cross-Atlantic liners are crowded with throngs of passengers. Each year sees a considerable increase in this traffic, which has now assumed such gigantic proportions as to tax the resources of the shipping companies to the utmost. On the other hand, considering the golden harvest that is reaped from it, no class of traffic paying steamships like their passengers, it is a matter for some surprise that the arrangements for the comfort and well-being of their clients are not above suspicion. We have heard of several complaints of a more or less disquieting nature, but without better evidence than has been forthcoming it has not been advisable to notice them. However, last week a correspondent of the *Pall Mall Gazette* again drew attention to the subject, and we gather from his article that the rush and scurry on some of these liners is so great, and the medical arrangements so haphazard, that great discontent prevails among passengers. It surely is a serious reproach to these great lines with their floating palaces if this be indeed so. The tradition, of course, at sea is that the doctor and his department are quite subordinate considerations, and in the past when a comparatively small number of passengers were carried, things were muddled through somehow. But when three or four thousand souls are on board a ship the medical responsibility is very great, and we should have thought that the medical officers would have been provided with the amplest accommodation for the reception of the sick, and with staffs sufficient for all emergencies. No doubt it would attract passengers greatly to know that a highly efficient medical service was available on a particular line, so that apart from humanitarian reasons, it ought to pay any company commercially to make such provision. But in the meantime it is pitiful to learn that the Italian Government are so dissatisfied with the arrangement made by the companies for their subjects that they send an official medical man of their own to see that things are properly looked after on the voyage.

A Pharmacy Prosecution.

A recent prosecution in Glasgow under the Pharmacy Acts revealed a curious state of affairs. The defendant was accused of calling himself a chemist and of keeping open shop and dispensing poisons both personally and through an unqualified assistant, although he was not a duly registered pharmaceutical chemist. It appeared from the evidence that he went to this shop 27 years ago, and after five years of managership took over the business on the death of the proprietor. During those 22 years nobody had ever interfered with him. On the passing of the Pharmacy Act in 1868 he had applied to be registered, but his application was refused. His lordship characterised the offence as serious because the Act was passed for the protection of the public, and he imposed fines to the extent of £9 13s. in all. This accident suggests that it would be well to supervise the qualifications of practising chemists periodically in all parts of the United Kingdom. The offence of "covering" is not unknown, neither is that of personation. Indeed, *mutatis mutandis*, much the same sort of evasion is probably practised in the case of medical qualifications. In every legally recognised profession it is necessary to devise some efficient control with maintenance of a register, but probably only the lawyers have anything like proper machinery for the purpose.

Camphor Eating.

There seems to be some remote prospect that camphor eating may be added to the list of drug habits that have been imported into the United Kingdom. So far, however there is no particular reason to dread the prevalence of so dangerous a craze, any more than that of morphia, or Indian hemp, or chloral, or other drugs that have figured on the list for years past. In South America camphor eating is said to be fashionable, its victims exhibiting diminished will power and shattered nervous and circulatory system common to the prolonged abuse of narcotic drugs. Camphor is credited with bringing a particular disaster upon its victims in the shape of general paralysis. The drug in question is prescribed much more commonly in America than in our own country, and it is possible that this fact to some extent accounts for the greater frequency of camphor eating on that side of the Atlantic. At any rate, we refuse to believe that the practice has gained any real foothold in the United Kingdom. It is always difficult to get direct evidence as to the actual facts and figures of a particular drug, and as a rule the investigator is forced to trust to the reports of the markets to show that the consumption of some particular drug has undergone a considerable increase.

Disinfecting Dangers.

A death from chlorine gas poisoning occurred recently in Manchester under somewhat curious circumstances. An elderly man was engaged by the Gorton District Council in Whitsuntide last to disinfect a house formerly occupied by a person suffering from an infectious disease. He used for the purpose chlorate of potash crystals, and hydrochloric and carbolic acids. During the process he inhaled some of the fumes, and developed an illness which proved fatal some ten weeks later. Medical evidence showed that bronchitis and laryngitis were present and that the condition was primarily due to the inhalation of the fumes. The incident points to the necessity of proper skill in the application of gaseous disinfectants, of which chlorine is probably by far the most irritating and deadly. Sulphurous acid is not only safer, but easier to use and cheaper, facts which quite account for its popularity. The death above alluded to took place before the new Compensation Act came into operation otherwise the Council would have been responsible for the occurrence. The possibility of death from disinfectant fumes should be widely known, and most certainly work in connection with irritants and dangerous gases should never be entrusted to anyone who does not possess the requisite skill and special knowledge.

The Notification of Disease.

The article by Dr. McWalter, published in our issue of the 31st ult., contained suggestions deserving of serious consideration from those interested in questions of public health. It is quite true, as Dr. McWalter points out, that there is a general assumption that the only diseases a medical officer of health is expected to check are those known as zymotic. This is a very narrow view of preventive medicine, but one which is tacitly gaining the field. The fact that it is only the zymotic diseases which are officially brought to the notice of the health authorities is doubtless one of the reasons for this strange narrowing of vision. Dr. McWalter suggests, therefore, a widening of the present system of notification, or rather the adoption of an entirely new method. His plan is that every practitioner should at regular intervals furnish the health authority of his district with a full list of the diseases under treatment, The list need not contain the names of the patients, so that no question of breach of confidence could arise. As a result of such information the sanitary authorities would be in possession of full knowledge as to the state of their districts at any moment. It is of interest that a similar system to that suggested is already at work in Buenos Ayres and various other cities.

An Anti-Vaccinist Mare's Nest.

His anti-vaccinist friends will hardly be very grateful to Mr. Lupton for his question last week to the President of the Local Government Board regarding an alleged death from vaccination at Croydon, since it gave Mr. Burns the opportunity of exposing another anti-vaccinist mare's nest. It has been stated, and Mr. Lupton repeated the charge, that a child had died at Croydon, on April 29th, as a result of vaccination; that the child had sores on the head, face, and arms, and had lingered in agony for three months. Fortunately, in the interests of truth, an investigation of the facts had been made by Dr. Copeman of the Local Government Board, and, consequently, Mr. Burns was able to contradict Mr. Lupton's statement to the fullest extent. The sores from which the child suffered had no relation to its vaccination, but were in fact the result of over-dosage with bromides, a drug administered in large quantity by the child's mother, on account of fits from which it suffered. Some twenty other children had been vaccinated with the same lymph as this child, none of whom had suffered from any untoward symptoms. Moreover, it does not appear that there was any foundation for the statement of the length of the child's illness, or even that the illness had been fatal. We could wish that more of the "platform facts" of the "anti-vacs" could be brought to the test of question and answer in the House of Commons.

PERSONAL.

Mr. Henry Morris, P.R.C.S., unveiled the Jubilee memorial window in Epsom College Chapel at the annual celebration of Founders' Day on July 27th.

Dr. R. P. Strong, of the American Bureau of Science, has been exonerated after enquiry by a special committee of the charge of inoculating Filipinos with cholera virus.

Dr. T. Outterson Wood has been presented by the staff and committee of management of the West-End Hospital for Nervous Diseases with a handsome silver bowl on the occasion of his retirement from the post of Senior Physician. Dr. Outterson Wood has been appointed Consulting Physician to the hospital.

H. S. H. Prince Alexander of Teck, G.C.V.O., presided on July 20th at a general meeting of the Special Appeal Committee of the Royal Waterloo Hospital for Children and Women. He announced that the building debt had during the last four years been reduced from £30,000 to less than £1,000.

Dr. Hector Mackenzie will open a discussion on the "Complications and Sequelæ of Pneumonia and the Treatment of Pneumococcal Affections by Serum or Vaccine" at the Royal Society of Medicine, on October 22nd next.

Lord Selby has been able to resume his duties as chairman of the Royal Commission on Vivisection. The Commission has now adjourned for the summer vacation.

A Clinical Lecture

ON

THE TREATMENT OF SUPPURATIVE OTITIS.

By R. H. WOODS, M.D., F.R.C.S.I.,

Surgeon for Diseases of the Throat, Nose and Ear to Sir Patrick Dun's Hospital.

The obscurity which surrounds some diseases of the ear and the neglect with which otology has been treated by those responsible for medical education in this country, have so deterred medical men from paying proper attention to the subject that many practitioners do not differentiate between those maladies that may be easily understood by anyone with a surgical training, and those that still puzzle the most advanced otologists.

Now it so happens that pyogenic diseases, from a public health point of view those of the greatest importance, come under the former class ; and it naturally follows that since they are better understood they can be better treated. A few words on the subject of suppurative otitis media may, therefore, not be out of place.

It will be convenient in the first place to draw a picture of a typical case of purulent otitis, and then see in what way the less typical ones vary from it.

Suppurative otitis may have its origin in a variety of ways. Among the more commonly observed are the following :—

1. As a complication of febrile attacks, especially where the fever is due to, or accompanied by inflammation of the membrane of the throat and nose, *e.g.*, measles, scarlatina, influenza.
2. From a chill such as follows exposure to a cold blast impinging on a small part of the body, as happens, for instance, when sitting in a warm room near an open window.
3. From mechanical violence such as a box on the ear, or plunging into water from a height.
4. From using the nasal douche or blowing the nose very hard, where, in addition to more or less mechanical damage, septic or other irritating material is forced into the tympanic cavity along the Eustachian tube.

From whatever cause arising, the sequence of events is the same in the vast majority of cases. The patient is seized with severe, deep-seated throbbing pain and a sense of fulness in the ear, accompanied with some febrile disturbance. This lasts in an untreated case from a few hours to several days. During this time, fluid, dark-coloured serum, is poured out from the swollen mucous membrane into the tympanic and accessory cavities.

If the attack is mild the quantity will be small and the swelling of the mucous membrane will not be great enough to prevent the exudation finding its way along the Eustachian tube. In all but the mildest cases, however, the fluid is exuded with increasing rapidity and the Eustachian tube becomes more and more obstructed by the swelling of its lining membrane, the pressure of the fluid in the tympanic cavity increases until the membrana tympani ruptures, and with the escape of fluid into the external meatus the patient gets relative relief. It will thus be seen that the interval of time between the onset of the attack and the rupture of the drum is chiefly a question of the severity of the attack.

From being at first reddish and serous, the discharge after a day or two changes its character, and becomes purulent or, more properly speaking, mucopurulent.

Two courses are open to an ear in this condition. The discharge may diminish and in a week or two finally cease and the perforated drum heal up ; in which event we call the case one of acute suppurative otitis media ; or the discharge becomes fœtid and continues indefinitely when it is called chronic suppurative otitis media. What is the essential difference between the two varieties, and what is it that determines to which class the case is going to belong ?

Some ten years ago, I undertook an investigation to help to clear this point. In an epidemic of measles and scarlatina lasting over five months 319 patients were admitted to the Hardwicke Hospital. I daily examined the ears of each of these patients. Many of them inflamed during the course of the general disease, some already had chronic purulent discharge.

I found that all the acute cases had this in common, viz., that only one kind of organism was present in the pus, while the pus from chronic cases invariably contained a great variety. This led to the generalisation that all cases of ear suppuration are acute at first, and only become chronic by being re-infected through accident, or want of proper precautions.

That this is the essential difference between acute and chronic middle-ear abscess is further borne out by the fact that it is the rarest thing to see a chronic otitis established in a case where proper treatment is carried out from the onset.

The object of treatment in such cases should then be to avoid this epi-infection by preventing extraneous organisms from becoming implanted in the tympanic cavity, or, to use a word suggested by a medical man, himself a sufferer, to keep the cavity monoseptic.

While it is probable that the external auditory meatus is not sterile, yet it is more likely that this secondary infection occurs when the tickling induces the patient to remove the discharge and allay the irritation with the tip of his finger The pus thus becomes inoculated and as it decomposes, the bacteria spread along it and gain access to the drum and mastoid cells.

The first step in the prevention of this transition from acute to chronic is the frequent removal of discharge by syringing. To accomplish this apparently easy task one or two points are worth bearing in mind. In the first place, it is more important that the fluid used should possess a solvent action on the muco-pus than that its germicidal power should be high. Therefore an alkaline solution is indicated, and I am in the habit of advocating bicarbonate of soda solution (ʒij. ad Oj.). This will emulsify and remove the discharge better than an acid or neutral one, and it has the great advantage in out-patient practice that it is inexpensive and handy. The syringe should have a fine nozzle, so that the size of the stream is small as compared with the lumen of the meatus. Only by this means can we be sure that the fluid searches the inner end of the meatus. It should be so easy to manipulate that the point of the nozzle can be held in front of the posterior wall of the cartilaginous meatus without risk of its slipping inwards and injuring the drum. For these reasons I have found an ordinary rubber enema-syringe with a fine ear-nozzle, most suitable, especially when, as is usually the case, the treatment has to be carried out by someone with no special training at the work. Glass syringes are inefficient on account of their small capacity and dangerous from the difficulty of holding them properly. The only objection to the rubber syringe is its price, which is sometimes prohibitive to the very poor.

When the meatus is thoroughly cleared of discharge it should be dried. The next step consists in introducing some drug into the meatus which will have the effect of inhibiting the growth of bacteria in the meatus. It matters very little what form this takes; an insufflation of boric acid is very good, but it needs an insufflator, and even then the powder may not go as far as it is intended to go. My own practice has been to put the patient lying on the opposite side, and to fill the ear with a saturated solution of boric acid in equal parts of rectified spirit and water, and allow a quarter of an hour to elapse before letting the drops run out. A little of the solution will remain behind, and even after the spirit and water evaporate, the boric acid has crystallised out and mixes with the fresh discharge, when it again begins to flow.

Neglecting tuberculous otitis, which is, of course, chronic from the first, if we want to prevent a chronic otorrhœa from being established, it is therefore only necessary to ensure that the ear be attended to once or twice daily by removing the discharge and impregnating the meatus with some unirritating drug having an inhibitory effect on the growth of bacteria.

For the prevention of acute otitis, it is most important that adenoids, when present, should be removed, as from their low vitality they favour inflammatory attacks which may spread to the ear along the Eustachian tube. Nasal douching should be avoided whenever possible, and under no circumstances carried out in any but the gentlest manner.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by G. H. Savage, M.D., F.R.C.P., Consulting Physician for, and Lecturer on, Mental Diseases, Guy's Hospital; Examiner in Mental Pathology, University of London. Subject: "The More Recent Treatment of the Insane."*

Probably the oldest medical man in the United Kingdom on the list of consulting physicians to a hospital is Sir Henry Pitman, who has passed his ninety-ninth birthday this month. Sir Henry graduated M.B. sixty-seven years ago, and commenced his long connection with St. George's Hospital half a century ago.

ORIGINAL PAPERS.

A PLEA FOR ACCURACY OF THOUGHT IN MEDICINE. (a)

By W. HALE WHITE, M.D.Lond., F.R.C.P.

Senior Physician Guy's Hospital, &c., &c.

It seems to me that sometimes we retard the progress of our science by being afraid to say we do not know. All human beings desire to find explanations. This is laudable, but it should not lead us to such hasty greed that we swallow false explanations which do us more harm than good, for then we resemble the unreasoning thirsty child who drinks salt water. Wrong explanations may be worse than none, because many people accept them comfortably without stopping to enquire if they are reasonable; but if no explanation was in the field, some thinkers would devote themselves to the problem which they now pass by, being soothed by the false interpretation, as, indeed, physicians were for the centuries during which the humoral doctrines prevailed.

It might be thought that, in the present scientific age, the habit of being content with rubbish in place of an explanation was a mental malady that had left us, just as the dancing mania of the middle ages has departed; but I am afraid we sometimes show symptoms of it. Accumulated observation and experience have taught us a great deal about gout, but all we really know of its pathology is that urate of sodium is deposited in some cartilages and other structures, and that there is an excess of uric acid in the blood. Nevertheless, often, instead of boldly saying to ourselves we do not know the cause of many cases of neuralgia, sciatica, bronchitis, and several other diseases, we set them down to gout; but where are the figures from the post-mortem room showing that urate of sodium is excessively frequently found in the cartilages or fibrous structures of, for example, people suffering from sciatica, or that they have an excess of uric acid in their blood? If we think accurately, we ought not to say a person has gouty sciatica unless we believe that he has urate of sodium in some of his cartilaginous or fibrous structures, or an excess of uric acid in his blood, and that these facts are etiologically related to his sciatica. Further, we ought, as a result of the experience of ourselves or others in the post-mortem room, to have such good evidence in support of our belief that we should not feel our reputation for skill in diagnosis seriously damaged if the patient were killed on the spot and no urate of sodium or excess of uric acid were found. Some, perhaps, feeling the impropriety of calling these conditions gouty on such slender evidence as others deem sufficient, and yet susceptible to the Mesopotamia-like soothing influence of words, irrespective of their meaning, have said: Here are a number of symptoms we cannot explain; we do not think they are due to gout, but let us imagine that the gout is irregular, or atonic, or undeveloped, or suppressed, and then we can ascribe them to it. In passing, the thought arises, if gout is undeveloped or suppressed, how can it cause symptoms? This method of nomenclature is worthy of Gilbert and Sullivan, but, seriously, is it creditable? As Sir Dyce Duckworth says: "Without doubt, many morbid states have often been flippantly or erroneously set down to irregular gout which owned no such designation, and thus a cloak for ignorance has always been at hand to throw over careless observation, ignorance, or wilful misinterpretation of symptoms." But others have gone further on the slippery downward path reached by the habit of jumping to conclusions, instead of saying we do not know, for they have not only declared that patients have irregular gout, but have linked it to one of the only certain pathological facts we know about true gout, and so have ascribed the symptoms of irregular gout to an excess in the blood of uric acid or bodies allied to it. Some do this without knowing the amount of uric acid present in the blood of a healthy person, without drawing any distinctions between endogenous and exogenous uric acid, without any attempt to estimate the uric acid in the patient's blood, without any experimental evidence that the injection of uric acid into the blood produces the symptoms in question, and without any thought of the fact that in some forms of leukæmia there is an excess of uric acid in the blood without the symptoms supposed to indicate suppressed gout. This doctrine has become so widespread that even the public tell us that their symptoms are caused by an excess of acid. Having assumed, not proved, that the symptoms the patient has are due to irregular gout, and having assumed, not proved, that this is due to an excess of uric acid, the next assumption made is that certain foods cause an excess of uric acid—some say carbo-hydrates, some say fats, some say proteids—and it would be quite easy for a patient to consult three doctors in turn, and, if he followed all, his diet would be water and nothing else. He who believes proteids harmful is the most artistic, for he has an eye to colour, and may as a concession allow white meat, although he prohibits red. Where on earth is the justification for this? Are there any experiments showing that steak leads to more uric acid in the blood than chicken? Have a hundred cases of so-called irregular gout been published and contrasted with another hundred similar in their treatment, except that in one series red meat was replaced by an equal amount of white? Surely you will agree with me that all this is not a credit to us as members of a scientific profession. The simple fact that although gout has become much less common, the consumption of meat has enormously increased, ought alone to make those who forbid proteids pause. The imagination of some has carried them still further. The fact that both gout and chronic osteo-arthritis are long-lasting diseases of joints has led them to think that as sufferers from one should be dieted, so those afflicted with the other. Hence we find patients who have chronic osteo-arthritis forbidden various articles of food, sometimes, for example, sugar. Looked at calmly, this is extraordinary, for there is not an atom of evidence that any particular article of food influences chronic osteo-arthritis.

(a) Abstract of Address in Medicine, delivered at the Exeter Meeting of the British Medical Association, 1907.

Sometimes we attempt to pacify this dislike to acknowledge that we do not know, by words which do not really help us at all—in fact, by lulling us into the belief that they explain facts when they do not, they lead us to imagine that our knowledge has rock for its foundation, when in truth it is built upon sand. For example, a teacher tells his students that alcohol is the cause of the peripheral neuritis from which the woman before him is suffering; but in saying this he fails to explain the remarkable facts that the disease is commoner in women than in men, and picks out the anterior tibial nerves before any others. There must be something different in the nerves of women from those of men and of the nerves in women the anterior tibials must be different from the others. Now, is the opportunity for the soothing influence of words; instead of being helped to face these facts as inexplicable in the present state of our knowledge, we are told that alcohol has a selective action upon these nerves especially in women, just as lead is said to have a selective influence on the musculo-spinal nerves. But does this help us? Surely not. It merely restates the fact that is evident to everybody; it is no explanation, but only an attempt to befog us with words and so possibly to retard the true explanation.

One of the greatest discoveries ever made in medicine will come to pass on the day when the mysteries now concealed by the phrase "selective action," are made plain, and we understand why, for example, the rash of measles comes first on the forehead; that of the scarlet fever on the chest; that of typhoid fever chiefly on the abdomen; and why, of all nerves in the body, the poison of diphtheria is specially harmful to those supplying the palate and the ciliary muscle.

Want of time prevents my bringing forward other instances of the years of delay in arriving at a truthful diagnosis that follow from cowardice in acknowledging that we do not know the cause of many symptoms; but it would not be difficult to do so, especially from among chronic diseases of the joints and diseases of the heart. I notice at the present time an increasing tendency to consider the muscle of the heart to be at fault; I believe that in the past we have not considered this nearly as much as we ought, and probably we have often overlooked disease of the cardiac muscle, but, unless we check our clinical work by histology, we run great danger of believing disease of the cardiac muscle to be present when it does not exist. I think I could show that the heart has often been said to be feeble or dilated on insufficient grounds, and the orthodiagraph will, I think, teach us that we have frequently been in error when we have thought the heart altered in size, just as the clinical use of the manometer has taught us that the estimation of the arterial tension by the finger is not so accurate as we have been inclined to believe.

He is the best physician who spends much of his time in the post-mortem rooms, and is not afraid to say he does not know. But the inability to make this confession is not peculiar to our profession. Since I drew up this address I have come across the following from the pen of Sir Alfred Wills:—"A constant source of difficulty in judicial investigations lies in what seems almost like an ineradicable tendency of human nature—an impulse to appear to know everything about occurrences of which the witness in reality knows but a part, and often a small part. . . . It seems to require some moral courage to say, "I don't know." It is not that the witnesses mean to deceive, but they have reasoned out what they never really observed, and confound the impressions so produced with those of actual observation." With doctors the temptation not to acknowledge they do not know is particularly strong, for patients are often so insistent upon an explanation that they thrust one upon the unfortunate doctor. Let us hope that they will do this the less as general education improves.

Talking of unwillingness to confess our ignorance, leads us to think of instances in which, while trying to treat medicine scientifically, we are woefully inaccurate, because we make excursions into sciences in which our training is inadequate. For example, the light and airy way in which some of us play with figures, as though there were no science of statistics, is astounding. Professor Karl Pearson truly says: "Approaching pathological inheritance from the modern statistical standpoint, it is almost heart-rending to notice the great amount of effort and energy wasted in the collection of data bearing on the inheritance of disease, but, unfortunately, much effort and energy have been thrown away upon other medical statistics, besides those connected with inheritance."

It must be left to expert statisticians to reform technical errors, but it is easy to indicate a few that are obvious. Frequently the mistake is made of dealing with far too few figures; often the very data are wrong, as we have just seen in connection with the hæmatemesis. Allowance is rarely made for the number of persons alive at different ages; it is very common to see figures published believed to prove the effect of this or that treatment without any allusion to the rapidity of recovery if no treatment had been adopted, and often the figures do not tell us what we desire to know. For example, statistics are published showing the frequency of recovery after some difficult operation. In the first place, for these to be of any practical use, we want to be able to contrast them with figures showing the mortality among those not submitted to operation. We ought to compare the expectancy of life among those who are not operated upon with that of those who submit to operation, for it is clear that if the operation considerably shortens the life of many, the total harm done by the operation may be more than the total good. Then, again, although it is interesting to know the degree of perfection to which any particular surgeon can carry the difficult art of operating, and so lower the mortality, yet, as all the patients cannot possibly go to the one skilful man, it is far more important to know the usual mortality among operating surgeons. These are only some of the points we have to consider, but let us take as an illustration the operation for a gall-stone impacted in the common duct. When trying to estimate the propriety of this we must bear in mind that when impacted in the common duct a gall-stone rarely causes death. From the years 1854 to 1894, only one patient not operated upon died in Guy's Hospital from an impacted gall-stone, the total number of deaths from all causes having been over 20,000. Naunyn has only once known the condition fatal. Some distinguished surgeons have operated upon several cases with complete success, but on the other hand, Mr. Bland-Sutton, doing the right thing and taking the figures not only of an individual surgeon, but from the chief London hospitals, and the Leeds and Newcastle Infirmaries, finds that out of 35 cases operated upon, 10 died, or nearly 30 per cent. But it might be urged that, bearing in mind the risk of fatal cholangitis and the tediousness and discomfort of passing an impacted gall-stone naturally, it is worth while to submit to operation, but before coming to this conclusion we must proceed very carefully, considering the high mortality following operation. Further, it is notoriously difficult to distinguish between an impacted gall-stone and malignant disease, so that in estimating the benefit that follows operation, we must take into account the shortening of life, owing to operation, among those who are operated upon in the belief that they have a gall-stone, although they really have malignant disease.

Please let it be understood that I am not in any old-fashioned way objecting to the advances of surgery. Far from it. The debt that physicians owe to modern surgery is very great; every year hundreds of people whom we physicians are powerless to help have their health restored to them by surgeons, and my surgical friends know well that not a week goes by but that I seek their aid. Nor am I here attempting to decide whether gall-stones should be excised from the common duct. The sole reason why I have taken an example of an operation upon medical cases to illustrate the care which must be exercised before arriving at a conclusion derived from figures, is that it is easier to see the result of a surgical operation than that of other modes of treatment; but I can readily take an instance from medicine, namely, the treatment of typhoid fever by bathing. Many large collections of cases have been published showing that if all the patients whose temperature exceeds a certain point are bathed, the mortality is lowered, and from that fact it is argued that all patients whose temperature exceeds that point should be bathed. But this does not follow, for supposing the bathing killed some who would otherwise not have died, but saved more who would have died if they had not been bathed, the mortality would be lowered, although the treatment would have killed some. Surely the right thing to do is not to bathe all, but to select to the best of our judgment those who should be bathed.

But when we have got our figures, the problem is often much more obscure than any of those just quoted, and demands a special training in the use of statistics that few doctors possess. A good illustration of the extreme difficulty of dealing with medical statistical problems is the question whether tubercular disease is hereditary. Often the evidence is fallacious, as, for example, when the writer forgets that all experience gained in the post-mortem room shows that many have tubercular disease who, as far as we know, gave no evidence of it during their life. Even figures from life insurance societies dealt with by actuaries are not free from fallacies of evidence, for they can take no account of those who are born of tubercular parents and die of tubercular disease without coming up for examination for life insurance. Often the reasoning is fallacious also, as, for instance, it is stated that such and such a proportion of sufferers from phthisis have consumptive parents, forgetful of the fact that this is worth little, unless we know what proportion of people who have not got phthisis have consumptive parents, and, beyond obvious pitfalls such as these, there are others that only the expert statistician can avoid. A few years ago, when it was discovered that there could be no phthisis without infection by tubercular bacilli, many of the medical profession, without any careful consideration, threw overboard the belief that inheritance played any part, and it was maintained that the children of tubercular parents were not more liable than others to phthisis, but Prof. Karl Pearson has recently published a paper in which he states that the inheritance of a special liability to infection by tubercle bacilli plays a very important part. Much has been made of cases in which it appeared that phthisis has been transmitted from husband to wife or *vice versa*, but as a rule, no attempt is made to calculate the probability that both might have such a common disease quite apart from infection from one to the other, and, therefore, it is interesting to read that Prof. Karl Pearson says: "There is clearly no need in such cases to appeal to infection from husband or wife to account for the small number of cases in which both parents suffered." I am afraid that frequently we describe conditions as having a special association without any endeavour to determine whether they are more frequently associated than might he expected as a matter of chance. The statistics about insanity and cancer also show the extreme difficulty of a proper use of medical figures. I have often urged what I am glad to see he urges that, as to deal with figures requires a special training, which is enjoyed but by few of us, we should not draw conclusions from statistics unless we obtain the help of those specially educated to their use. But statistics are only part of a larger matter, namely, the extraordinary width of knowledge required for our science of medicine.

Yet another hinderance to the advance of medical knowledge is the acceptance of facts upon authority. Thus the hæmoptysis of phthisis was often ascribed to vicarious menstruation, although it occurs equally in men and women; it may be met with in females who are of such an age that menstruation does not take place, and it has no monthly periodicity; but perhaps the most striking instance of subservience to authority was the almost universal habit of bleeding solely because the teaching of the day said that people should be bled. Often patients were actually bled to death; yet those who did it were so blinded that they ascribed the death to the illness and not to the bleeding.

Not so very long ago, that extremely powerful poison, antimony, was given for many diseases because it was stated by authorities to do good. No one would now contend that any considerable proportion of the thousands of patients who took antimony were one whit the better for it. When a student begins his work he must for a little while accept some statements upon the authority of his teacher; but with every day of his career the necessity for this becomes less and less, for medicine is a science in which nature performs on every patient, experiments that those who have eyes to see can watch and so observe for themselves if the statements commonly made are correct.

Speaking of the use of antimony and venesection, as illustrating the harmful effect of authority, reminds us that no department of medicine shows this better than that which deals with treatment. Sometimes authority in one country advises different treatment from that employed in another. Thus, whilst in England we often give strychnine when the pulse is feeble, in Germany camphor is used for the same condition. This seems absurd, one or the other must be the better. Often little attention is paid to the natural course of the disease towards recovery; for example, many methods of treatment by drugs, electricity, serums or operation are said to benefit exophthalmic goitre, regardless of the fact that if the patient is put to bed and kept quiet, she will usually recover without any other treatment. With many diseases the natural tendency to get well is so great that, unless there is a strong consensus of opinion as to the efficacy of one particular mode of treatment, *e.g.*, iron for chlorosis, mercury for syphilis, thyroid for myxœdema, probably no special treatment by drugs does any good. It may be laid down that when more than two drugs are praised as benefiting any disease, probably no one that we know does so.

Unreflecting adhesion to authority has a particularly serious effect in keeping back the advent of correct knowledge, for, in the first place, when the authority is found to be wrong, much energy that might be utilised in the search for truth is expended in demolishing that which is false, and, in the second place it seems almost a law that we should rush to extremes of thought, so that having been for years wrong in one direction, we travel for years wrongly in another course, before attaining the true position. For example, for many years after it was shown that bleeding had been frequently practised for diseases in which it did harm, it was very rarely done, and many patients were, therefore, deprived of the relief it would have given them, and it is only now that we have learnt to correctly know when to employ it. "It is almost always the unhappiness of a victorious disputant to destroy his own authority by claiming too many consequences or diffusing his proposition to an indefensible extent."

Much of this excessive zeal for treatment by drugs arises not only from an unwise adhesion to so-called authority, but from a lack of appreciation that pathology is the basis of all medicine. The primary duty of a physician is to find out what is the matter with his patient; proper treatment can only be secondary to that. Another reason for incorrect treatment is that many say, "You must do something." I can never see the reasonableness of this. The very fact that the doctor does not know what to do is actually used as a reason why he should do something; surely it is the very reason why he should do nothing, for he may well do more harm than good. To know when to interfere and when not to interfere with Nature is a fine test of the sagacity of a clinical physician. Do not, however, imagine I am urging that treatment is rarely of use. Far from it. Never at any period in the history of medicine has treatment been more skilful than now, and never did out art save more lives than now.

The last point to which I have time to draw your attention is that it usually requires considerable trouble to train ourselves to receive new ideas properly, and by failing in this respect we retard the progress of medical thought. In this matter there are three kinds of mind. Those having the one usually claim that they are critical, but they are obstructive rather than fair critics. For the most part, they are extremely slow to assimilate anything new, strange to say they frequently pride themselves on this, and take great comfort from the sad fact that many suggestions which, when first promulgated, appeared fruitful have turned out to be barren. Those having the other are easily enticed away by new notions just because they are new; they absorb new ideas too rapidly without digesting them; in popular language they are ready to swallow anything. Fortunately, our profession contains many who fall into neither of these classes because they have an evenly balanced mind, trained to estimate the value of novel suggestions.

Pardon me for having in these fragmentary remarks only stated what you all know, and what many have taught at various times during several centuries. My excuse for urging a plea for accurate thinking is that the more accurately we think the more rapidly will medicine progress.

The Board of Governors of the Royal Hospital, Kilmainham, have selected Lieutenant-Colonel R. J. Windle, Royal Army Medical Corps, for the appointment of physician and surgeon to that Institution in succession to Lieutenant-Colonel F. S. Heuston, C.M.G., whose tenure will expire on September 30th.

THE CARE OF TUBERCULOUS CHILDREN. (a)

By T. N. KELYNACK, M.D., M.R.C.P.

Honorary Physician and Medical Adviser to the Children's Home and Orphanage; Honorary Physician to the Mount Vernon Hospital for Consumption.

Tuberculosis still remains one of the greatest scourges of child life. In the Anti-Tuberculosis Campaign it is essential for success that adequate provision should be made for the protection of infants and children from a tuberculous invasion and adequate means secured for the early detection and prompt treatment of all forms of tuberculous disease originating during the all-important initial years of life.

In the study of this question pathological considerations should receive attention. More than one-third of all deaths at the ages of 15 to 35 are from phthisis. Much of this mortality is the harvest of the tuberculous seed sowing in infancy and childhood. It is said that tuberculosis has increased about 20 per cent. among London children during the last fifty years. Of the 1,200,000 new lives added every year to the population of the United Kingdom from one-fourth to one-third are born to want and squalor, conditions making for tuberculosis. Tuberculous lesions are found in children under 15 years of age dying from all maladies in about 40 per cent. of the cases. Tuberculosis may be contracted during intra-uterine life, but is rare. An inherited predisposition of soil is certainly transmitted. Milk is probably an unimportant source of tuberculous infection. While agitating for hygienic control of our milk supply it is essential that the personal responsibility of parents and others in maintaining a healthy environment for the child should be insisted on. Von Behring's contention that tuberculosis is commonly acquired from tuberculous milk in France has not been substantiated, but his views regarding infection by tuberculosis in early life, its long latency in the glands of the abdomen and thorax, and its development when childhood's days have passed, are being supported by recent investigations and will go far to revolutionise theoretical conceptions and reform practical prophylactic measures.

Pulmonary tuberculosis occurs much more frequently in children than is usually believed. Professor Emmett Holt states that in nineteen months sixty-seven cases of pulmonary tuberculosis were under treatment in the New York Babies' Hospital, sixty-two under two years and fifteen under six months of age. By adopting a new method he was able to demonstrate the presence of tubercle bacilli in the pulmonary secretion in over 80 per cent. of the cases: the possibility of infection at home was known to have existed in at least 40 per cent.

Tuberculosis is met with among school children to an extent which demands serious attention. The promised medical inspection for public elementary schools should do much, if conducted by skilled examiners, in detecting the early evidences of commencing tuberculosis and in recognising children predisposed to tuberculous disease. Among the inmates of our Children's Home and Orphanage 25 per cent. are said to be the offspring of consumptive parents. Dr. Leslie Mackenzie states

---

(a) Abstract of a Paper presented to the Section of Diseases of Children at the Exeter Meeting of the British Medical Association, Thursday, August 1st, 1907.

that 14 cases of pulmonary tuberculosis were noted among six hundred Edinburgh school children; and in three cases among Aberdeen children. Dr. William Robertson, of Leith, detected six cases of tubercle of the lungs among eight hundred and six school children. Dr. Alfred Greenwood, among one thousand and twenty-eight Blackburn children, specially selected by school attendance officers for medical examination, found that 6.2 per cent. were phthisical. Dr. Wilkinson, among seven hundred and nine Oldham children, found seventeen with pulmonary involvement, a percentage of 2.3. Dr. J. E. Squire, after an examination of nine hundred London children in one school in a very poor neighbourhood, places "the proportion of cases of possible tuberculosis of the lungs at about 1.5 per cent."

The late Professor Grancher found evidences of predisposition to tuberculosis in something like 17 per cent. of the Paris school children.

All schools should arrange for thorough medical examination with a view to the early recognition of tuberculosis and the detection of all tuberculously disposed children. The French plan of removing children from tuberculously contaminated homes has proved advantageous. There is need for an extension to this and other countries of the German Forest Schools for consumptive and tuberculously disposed children. This country is miserably poor in its provision for sanatoria for children. Urban hospitals for tuberculous cases are to be condemned. Institutions taking adult consumptives are not suitable places for children. Many of the supposed advantages of a marine situation for tuberculous children are in a great measure imaginary. Consumptive cases are certainly best dealt with at high and dry and sheltered inland stations. There is urgent need for co-ordination of knowledge and co-operation of practical effort. Individual benefit and national advantage would accrue from the founding of a National Society for the Study and Care of Tuberculous Children.

OBSERVATIONS ON THE

DETERMINING CAUSE OF THE FORMATION OF NASAL POLYPI. (a)

By EUGENE S. YONGE, M.D. (Ed.).

Honorary Assistant Physician, Manchester Hospital for Consumption and Diseases of the Throat.

The author's conclusions, which refer exclusively to *mucous polypus* of the nose, may be summarised as follows:—

(1) Mucous polypus may be regarded as a pathological condition possessing certain definite characteristics which distinguish it from other swellings and new formations that may occur in the nasal cavity. (2) Mucous polypus is essentially, and in its earliest stage, a patch of mucous membrane, which has become œdematous, the pedunculated appearance, which polypi commonly assume, being chiefly the result of physical causes acting on the primary patch of swollen œdematous mucosa. This tendency to become pedunculated is of course not peculiar to the condition in question, but is shared by many other intra-nasal new formations. (3) In the majority of instances the condition appears in both nasal cavities without any apparent local cause, which is sufficient to account for it. This circumstance, combined with other considerations, leads to the supposition that there is usually a constitutional element in its production which, together with certain local influences, is capable of setting in action that which is considered, by the author to be the proximate cause. (4) In a minority of instances there is present a condition (*accessory sinus suppuration*) which is a presumptive local cause of polypus-formation. But since this process does not necessarily lead to the production of the disease, and since the disease may occur without its intervention, it is reasonable to conclude that the process is instrumental in causing polypus-formation only when it sets in action the factor which is the actual proximate cause. (5) In a certain number of instances there have been observed changes of an inflammatory nature in the bone and periosteum, which would presumably be sufficient, if they were shown to be primary to the changes in the mucous membrane, to account for the incidence of œdema in that structure. But in view of the facts that in numerous specimens of bone, underlying polypi, no bone disease has been found; that polypi have been demonstrated to occur on a mucous membrane which shows only a superficial inflammation and in which the deeper parts are not diseased, and that the lesions in the bone, when present, have been shown by several observers to be secondary to the specific process in the mucous membrane, it may reasonably be inferred that bone-disease is not essential to the production of mucous polypi and that the primary œdema of the mucous membrane must ordinarily be referable to some other factor. (6) The *proximate cause* of the œdematous infiltration of the mucous membrane, which represents the primary and essential process of polypus-formation is in the author's opinion, the obstruction of certain definite capillaries and veins, brought about by a circumstance (dilatation of the ducts of the mucous glands, and, to a lesser extent, of their acini) which produces its specific effect by causing pressure on, and, probably, obliteration of the vessels, which surround the structures in question in the form of close networks. (7) An inflammatory process in the mucous membrane is a very common antecedent and accompaniment of polypus-formation, but since the former condition is obviously present in varying degrees of intensity and persistence, in a great number of cases which do not at any time give evidence of polypus-formation, it appears reasonable to suppose that inflammation of the mucous membrane does not of itself, lead to polypus-formation, but only does so by securing the intervention of another factor. The presence or absence of this factor (glandular dilatation) determines, in the author's opinion, whether an inflamed mucous membrane undergoes œdema and subsequent polypoid changes or whether it escapes such changes. (8) The evidence in favour of the contention that this particular factor sets in action the proximate cause which leads to the primary œdema, is derived from pathological, clinical and experimental observations.

Pathological.—(1) The frequent observation of distension and cystic dilatation of the glands in mucous polypi, and the almost invariable (a) presence of the condition (in the specimens examined) in the underlying and contiguous mucous membrane wherever this was œdematous. (2) The absence of the glandular changes in those instances of inflammation in which polypoid changes were not present. (3) The fact that an inflamed mucous membrane and one in a state of polypoid change appeared to show all residual circumstances in common except one — the glandular changes.

(a) **Abstract of Paper read before the Section of Laryngology and Otology at the Annual Meeting of the British Medical Association, August 1st, 1907.**

(a) **It is of course not necessary, from a logical point of view, that two circumstances should be in INVARIABLE association in order that an etiological relationship may be assumed, a FREQUENT conjunction being sufficient.**

Experimental.—(1) The fact that the production of an inflammatory process in the nasal cavity, in suitable animals, was not followed by any indication of polypoid change or of any distension of the glands. (2) That the production of an inflammatory process in similar animals, produced in the same manner, by similar agents and lasting for the same period of time, but combined with measures calculated to cause overloading and distension of the mucous glands, was followed by polypoid change in the mucous membrane, the latter showing marked distension and cystic dilatation of the glands on histological examination.

Clinical.—The author's hypothesis appears to offer an adequate explanation of the incidence of mucous polypi occurring under dissimilar circumstances and conditions. It is capable also of rendering intelligible the constitutional element that is evident in many instances; the common occurrence of polypi in cases where glandular disturbances are known to exist, and, at least in some instances, it helps to solve the question of recurrence. Moreover, the theory assists, in the presence of other known factors, in explaining the age-incidence; in reconciling the discrepancy between the incidence as observed *post mortem*, and the incidence as observed clinically, and lastly in explaining the localisation of polypi in special areas of the nasal cavity and in certain of the accessory sinuses.

THE CO-ORDINATION OF THE PUBLIC MEDICAL SERVICES. (a)

BY ARTHUR NEWSHOLME, M.D., D.P.H.

Medical Officer of Health, Brighton, &c.

THE following is a summary of Dr. Newsholme's paper in introducing the discussion:—The scope of preventive medicine is no longer confined to germ-born diseases, but extends to such early treatment of any disease as will secure a less severe or less protracted later stage of disease.

The community as well as the individual is interested in this wider definition of preventive medicine, though, as shown by the serious loss of life and health still due to avoidable causes, this is only partially realised. Poverty and disease act in a vicious circle, and the practical problem considered in this paper is the means by which people may be prevented from becoming poor by preventing them from becoming sick.

Official and voluntary agencies now at work show how much is already being done in the communal treatment and prevention of sickness. The list of these agencies given in the paper shows that the distinction between prevention and treatment has never been maintained. A rapidly-increasing proportion of total sickness is being treated in voluntary and in State or rate-supported institutions.

Are we getting a satisfactory return for this increasing burden on rates, taxes, and charity? Whether viewed from the standpoint of patients, doctors, or of the public health, the present state of the medical service must be condemned as unsatisfactory.

The conditions of private medical practice among the poor are admittedly most harassing and unsatisfactory to the doctor. To the patient they are equally unsatisfactory, for (1) diagnosis is belated, and (2) treatment is curtailed owing to expense. (3) In dispensaries, etc., there is a serious waste of time. (4) There are no co-ordinated arrangements for medical consultations. (5) Valuable information as to the incidence of disease is wasted. (6) There is a great waste of information as to the existence of conditions conducing to disease.

These defects can be overcome, as is seen in the co-ordinated arrangements where the notification of consumption is successfully at work. Thus the visit of an officer to the notified patients sets in operation all the prophylactic, curative and sanitary measures which are needed, equally for the welfare of the patient and of the public. Undetected cases are recommended for diagnosis and treatment. Sanatorium training and treatment are secured.

These defects are not overcome, for instance, when the organisation for the medical supervision of scholars is separate from the general public health administration of a district. Much of the medical inspection of scholars, if it is to be efficient, must be done by interviewing parents, and much of it involves home visits. The home is the point from which many of the evils discovered by medical school inspection will have to be attacked and controlled. In actual fact parents will not tolerate dual medical examinations for school purposes, and on the other hand neither school doctor nor medical officer of health fulfil the complete needs of the case. These will only be met when district doctors are appointed by each municipality, and these doctors are co-ordinated with the mechanism of preventive medicine, enabling us to secure the early systematic and unstinted diagnosis and treatment of all disease before, even more than at, school ages.

The present state of medical service is evidently transitional. Neither provident dispensaries nor cries against "hospital abuse" and "under cutting" practice have been able to hinder the steady progress towards the treatment of disease at the expense of the community; nor is it possible to arrest this trend. What has hitherto been done in the collective treatment of disease is merely a phase in the evolution of the system which will effectually ensure the early recognition and proper treatment of all diseases. Such a system would justify itself economically by the corresponding reduction of sickness and of inefficieny; in short, the justification of a municipal medical service both economically and medically consists in its being a branch of a general system of preventive medicine. By this means information of preventive value will no longer be allowed to run into *culs-de-sac* and be lost, preventive medicine being regarded as a whole, and its many fragmentary portions being no longer allowed to continue relatively impotent by being detached from single executive control.

A SMALLPOX case has been notified to the health authorities of Sunderland. The patient is a well-known merchant, who has just returned from a visit to Denmark, where he contracted the disease. He has been removed to the borough sanatorium.

MILK IN RELATION TO HUMAN TUBERCULOSIS. (*a*)

By HENRY E. ARMSTRONG, D.Hy., Durh., M.R.C.S., L.S.A.

Medical Officer of Health, Newcastle-upon-Tyne.

THE Vehicles of Media by which the Bacillus of Tuberculosis gains entrance into the bodies of previously healthy human beings are the following, viz. :—

(*a*) The milk and milk-products (1), consumed as food, of tuberculous cows; (*b*) The milk of a tuberculous human mother; (*c*) The flesh of tuberculous animals consumed as food; (*d*) Dried expectorated matters and other infectious discharges of consumptive persons inhaled or swallowed as atmospheric dust, etc; (*e*) Heredity; (*f*) Marriage of the tuberculous; other vehicles, etc.

This division of the subject may be considered under the following heads, viz. :—

(1).—THE PREVALENCE OF TUBERCULOSIS AMONG DAIRY COWS.

The Report of the Royal Commission on Tuberculosis issued in 1898 states that "of all the animals slaughtered for food in Great Britain and Ireland those of the bovine race seem to be more largely affected with tuberculosis than any other." In the absence of statistical information as regards our own country the Report proceeds to show that in Leipzig, of 9,303 cows slaughtered, 4,048 or 43.51 per cent., were tuberculous. The proportion of such diseased cattle in the English cow-houses, which has been publicly and authoritatively stated at about 30 per cent. (MacFadyean) (2) may not be excessive. In the year 1901 there were 1,887,414 milch cows in England, and 4,102,061 in the United Kingdom.(3) Thirty per cent. of these means upwards of 560,000 tuberculous milch cows for England alone, and nearly 1¼ millions for the United Kingdom. The bare idea of the amount of possible human tuberculosis from the milk of so immense a number of diseased cows is appalling. Nothwithstanding this truly dreadful possibility the Report above quoted gives prominence to the following statement. "It is not proved to our satisfaction that tubercle bacilli has ever been detected in milk unless drawn from a cow with tuberculosis of the mammary gland."(4)

(2).—THE ENTRANCE OF TUBERCLE BACILLI INTO MILK, AND THE STATE OF MILK SUPPLIES IN RELATION TO TUBERCULOSIS.

In a well-known work(5) the means of entrance of uberculosis into healthy cowsis described, and may be summarised as follows :—(*a*) Tuberculous excretions and discharges conveyed to soil, air, water, fodder, and general surroundings (premises, stables, straw, stable refuse, utensils); (*b*) The milk of a tuberculous animal may be consumed by other animals; (*c*) The bacilli may be distributed by the cough of a tuberculous cow (Ravenel) or (*d*) by the saliva of a cow in licking In this way she may also infect the surface of her udder, and thereby the milk, by means of the hands of the milker.

Each or all of these ways may lead to the contamination of the milk after yield. By the repulsive habit of spitting on the hands before milking, or by dried expectoration in a cowhouse, a consumptive milker may infect the milk after it has left the teats of the cow.

The foul state of many cow-houses, both in town and country is only too well known, and ample illustration of this is on record.(6) It is right to add that of late years great improvement has taken place in many town cow-houses—but most of those in rural districts are as insanitary as ever. Dr. Hope, of Liverpool, has shewn that in town-yielded samples of milk the tubercle bacillus was found in 2.8 per cent., whereas in supplies sent from the country 29.1 per cent. were found to be tuberculous. Speaking from personal experience, the writer affirms that the cow-houses in Newcastle and the surrounding country districts are in much the same condition as in other places; and he has every reason to believe that a bacteriological examination of the different urban and rural milk supplies sold in the city would disclose results similar to those found in Liverpool and elsewhere. Even accepting the untenable hypothesis that cow's milk is only rendered infectious when the udder becomes diseased—the difficulty of diagnosing such disease at an early stage in time to prevent the use of the milk for food is so great as to put beyond the range of practical utility most of the apparent value of the suggestion.

(3).—THE EXTENT OF THE DISEASE CAUSED OR CAUSABLE BY MILK AND ITS PRODUCTS.

The milk trade is one of the most complex of organisations. Under defective management it may become a most elaborate means for the spread of different infectious diseases, and of none more frequently than tuberculosis. The fact that milk as sold to customers is the mixed yield of perhaps from 10 to 50 different cows—a certain proportion (perhaps a large one) of which are possibly tuberculous, renders the entire product, if so infected, a most potent agent of evil. As milk is distributed night and morning to the houses of dairy customers, by many of whom—especially the children—it is consumed raw, the opportunities of the dissemination broadcast of the virus of tuberculosis or other disease are far beyond comparison greater than with any other article of diet. The spread of infection from a diseased cow may go on for many months without detection, whilst her milk is being consumed without suspicion. That the many forms of tuberculosis among the young, and indeed among all ages. are not oftener traced to the milk-supply is the consequence not of the harmlessness of the milk itself, but of the complexity of the circumstances attending its distribution, together with the very nature of the disease and the conditions of its development. In the case of an outbreak of scarlet or enteric fever, of which there have been several hundreds within the last twenty years or so, the suddenness of the outburst, the nature of the ailment, the common routine of inquiry invariably made by the special inspector, and a host of other circumstances, point at the outset to the milk-supply as the possible, if not probable, cause. But, with tuberculosis this is not so. This disease is insidious in its approach; its period of incubation is unknown; the signs of its presence are for a considerable time indistinguishable from those of other ailments; and the means of tracing its probably remote origin are not available. Hence the impossibility in the present state of our knowledge of presenting evidence of the extent to which the disease may be attributed to milk or any other individual cause. This circumstance has led to the idea on the part of some that "if there had been anything like the danger from the meat and milk of tuberculous cattle that medical officers of health say there is, we should all have been dead of tuberculosis long ago!" Such an idea, if true, would apply to all infectious diseases, which would never cease until they had exterminated the entire human race. But they do not spread in this way for several well-known reasons which it is unnecessary here to state; and the same applies to tuberculosis, with respect to which it may be added that special predisposition on the part of some persons and exactly the opposite condition on the part of others, are special characteristics of that disease. It is stated on good authority that about 90 per cent. of the cases of tuberculosis among calves and swine have been proved to originate in feeding with infected milk.(1)

(4).—THE DIFFICULTY OF RECOGNISING TUBERCULOSIS IN DAIRY CATTLE BY ORDINARY MEANS.

The difficulty of diagnosing tuberculosis by ordinary physical means at any but the most advanced stages of the disease is universally recognised; but this very fact is an element of the greatest mischief in the possibility it allows for the continuous spread of infection for a long period, from a diseased cow. Daily visitations at cow-houses afford but little information to the inspectors of the sanitary authority as to the health of dairy cattle.

(5).—THE TUBERCULIN TEST AS A MEANS OF DIAGNOSING TUBERCULOSIS OF CATTLE.

The Royal Commission of 1898 in their Report, s. 15, "recommended that funds be placed at the disposal of the Board of Agriculture in England and Scotland, and of the Veterinary Department of the Privy Council in Ireland, for the preparation of commercial tuberculin, and that stock-owners be encouraged to test their animals by the offer of a gratuitous supply of tuberculin and the gratuitous services of a veterinary surgeon on certain conditions."

"These conditions shall be:—(*a*) That the test be applied by a veterinary surgeon; (*b*) That tuberculin be supplied only to such owners as will undertake to isolate reacting animals from healthy ones; (*c*) That the stock to be tested shall be kept under satisfactory sanitary conditions, and more especially that sufficient air-space, ventilation, and light be provided in the buildings occupied by the animals."

The Commission further recommended the circulation among agricultural societies of instructions for the proper use of the tuberculin test, with explanation of the significance of reaction, and direction for effective isolation of re-acting animals.

The above recommendations are sufficient proof of confidence in the value of the tuberculin test. Although made eight years ago, so far as is known to the writer they *have led to no practical result whatever on the part of the British Government.* For this reason, and seeing the well known disinclination of farmers to speculation, and their not unnatural hesitation to experiment with the object of discovering disease in their herds, it is perhaps not surprising that the test has not become popular among them. The responsibility incidental to such a discovery may not be unconnected with their failure to adopt it. The magnitude of the task, and the claims for compensation involved have doubtless deterred the Government from pushing the subject forward on their part. Hence little or no progress has been made in England toward the elimination of bovine tuberculosis as a commercial project. Its compulsory extinction as a source of the greatest danger to human life has never yet, it is believed, been seriously proposed. What is the reason? "*If preventable, why not prevented?*"

(6) POSSIBILITY OF ELIMINATING TUBERCULOSIS OF CATTLE.

In reviewing the pros and cons of this momentous question the chief points for consideration appear to be the following:—(*a*) The tuberculin test is admittedly reliable as a means of detecting the disease; (*b*) Voluntary attempts to eliminate tuberculosis have been freely tried in Denmark and have met with a very large measure of success. To ensure complete success of the process compulsory and universally complete application of the principle is necessary; (*c*) The process of elimination should involve the immediate slaughter of all re-acters and the destruction of their carcases. Stock-owners should not be responsible for the carrying out of this great work for the public benefit; neither should they be at any pecuniary loss in its execution.

Fair compensation should be granted on compliance with requirements during a stated period whilst the process is in operation. Doubtless the knowledge of the sum of money that would be required for this purpose is the main objection to the enforcement of the measure by Government. Such an objection would not hold in the case of an acute and widespread epizootic or other disease, say of cattle plague, an outbreak of which in this country in 1865–6 involved the death of upwards of 233,000 head of stock. Here the first consideration was the stamping out of the disease as quickly as possible, and at any cost. Tuberculosis of animals is more widely spread than cattle plague has ever been; it is always chronically prevalent in our herds and dairies; whereas visitations of cattle plague are few and far between; and what is worst of all, it causes a vast amount of human sickness and death, which cattle plague does not do. Hence its distinction, both on hygienic and economic grounds, is more urgently called for than would be that of an epizootic disease of different kind. It is estimated that the disease in animals may be eliminated in a single year. It might be attacked in single counties or districts in successive years to diffuse over a longer period the cost of dealing with it. All fresh importations of cattle into a district after a given date should be subject to the test. If all stock-owners and butchers were required to purchase subject to guarantee against tuberculosis, as proved either by the tuberculin test or by inspection after slaughter, the test would rapidly become general. Owners would only be too glad to adopt it in self-defence, and other action necessary for the extinction of the disease would soon follow.

(7).—THE CONTROL OF THE MILK-SUPPLY BY SANITARY AUTHORITIES.

The control of the milk-supply of any district, to be satisfactory or complete, involves the necessity of frequent bacteriological examination of specimens drawn from the udders of each and all of the cows yielding milk for the supply of that district. This means that such examination should apply to the produce of dairies within the district and others sending supplies to it from without. A sanitary authority may take power to obtain the required specimens, and may carry it into effect in its own district; but to do so in the case of districts at a distance would be difficult and troublesome unless through the co-operation of the sanitary authorities of such districts. But under present conditions such co-operation is scarcely to be expected. For example: a large amount of milk is sent daily to London from Cheshire. Are the different rural authorities of the latter county to be expected to bestir themselves vigorously in order to condemn, in the interest of the distant metropolis, the cowsheds and milk-supplies of their own farmers, many of whom may be members of these same authorities? And how can London supervise the Cheshire dairies for itself?

The necessity for the regular and frequently repeated bacteriological examination of the milk-supply from every dairy cannot be too strongly insisted on. Tuberculosis of the udder is a well-known, though not by any means a common, form of the disease in cows, and the great danger in such cases of spreading the disease to consumers of the milk is admitted, even by the late Royal Commission, who cannot justly be charged with undue severity—at least to the dairy-trade—in their proposals for dealing with the milk of tuberculous cows, seeing that their protective recommendations extend only to animals with obvious disease of the *udder*, notwithstanding the fact that the milk of cows *without visible sign of tuberculosis of the udder* has been shown by many bacteriologists to be infectious.(1)

This systematic and general bacteriological examination of milk is all the more urgently required by the fact that dairy farmers are not yet compelled by law to take steps to ascertain whether their milch-cattle are all tubercle-free. The possibilities of spreading tuberculosis through the milk-supply are very great, inasmuch as in the case of one cow only having the disease in a large dairy-herd, her milk, mixed with that of the other cows, will contaminate the entire supply, which, being distributed twice a day for a lengthened period, and consumed largely by children and principally uncooked—whether in its natural state or in the form of butter or cheese—has thus greater possibilities for conveying infection than any other article of food. The ramifications of the milk trade throughout the United Kingdom are so complex and so intricate that no proper supervision in the interest of the consumer is at present practicable. Such supervision is possible only by the union of representatives of county councils and district authorities, both urban and rural, in one general body, with power to organise and cause to be carried out all such measures for the regulation of the production and distribution of milk as are required for the protection of the health of the consumers. The action of such a body need not by any means be limited to the control of the milk supply. In the national interest it might extend to the extinction of bovine tuberculosis, and other matters relating to public hygiene. The work for such an organisation is abundant, and if taken in hand will be found to increase year by year.

---

(1) L. Rabinowitsch, 1901, and Swithinbank and Newman, 1903.

A sanitary authority should have power to collect at the place of production samples of any milk intended for sale within their district. No power is given to deal with any form of tuberculosis in a dairy, no matter how extensive, other than the comparatively rare one in which the udder is affected; and how is the dairyman to be proved to know that a disease of his cow's udder is tuberculosis? The application of the tuberculin test to dairy cattle, even in cases of suspected tuberculosis of the udder, is not provided for. The Liverpool milk clauses also fail to afford the protection against, and means of detection of, tuberculosis among the dairy cattle yielding the milk-supply for the city, which the public health demands. The medical officer of health may, it is true, by a very tedious and roundabout process, obtain an order to prohibit the sale of milk at any dairy, but *not unless he is of opinion that such milk has caused, or is likely to cause, tuberculosis to its consumers!* How, without previous application of the tuberculin test, is he to obtain the information on which to form such opinion? How long may the distribution of such milk have to continue to cause tuberculosis before the medical officer can possibly feel justified in concluding that it has done so? As it stands, the supposed "power" is a pure delusion.

(8).—Action Desirable.

Every sanitary authority should have the power to enforce, and should be required to enforce, the following provisions, viz.:—(1) to apply the tuberculin test to, and (2) to take such specimens as may be required of the milk of any cow, the yield of which is intended for sale in the district of such authority; (3) to prevent the sale of milk of any cow re-acting to the tuberculin test, or found to be affected with tuberculosis in any form whatever; (4) To destroy any dairy cow re-acting to the tuberculin test and to compensate the owner, in the event of his compliance with the requirements being approved by the sanitary authority; (5) to require that no fresh cow shall be brought into any dairy for the production of milk for sale that has not previously been recently tested with tuberculin and failed to re-act thereto.

The administration in detail of the foregoing and other requirements for the regulation of the milk trade ought, in the national interest, to be directed by a combination of sanitary authorities, as elsewhere indicated in the present report.

(9).—THE ATTITUDE OF THE LATE ROYAL COMMISSION IN RESPECT TO THE MILK OF TUBERCULOUS COWS, AND ITS CONSEQUENCES.

Among much that is valuable in the report of the Royal Commission of 1898, there is also much that is grievously disappointing. The observations on milk-supply (ss. 39 and 42) and recommendations 7 and 8 on the same subject are, as already stated, directed against the milk of cows with diseased udders only. The sale of the milk of other tuberculous animals is not condemned and therefore, by inference, is sanctioned by the Commissioners. In view of the abundance of proof as to the deadly nature of such milk, this is a lamentable fault in the report. As a whole, the sections of the report above referred to may, not inaptly, be characterised as milk and water.

The effect of the pronouncement of the late Royal Commission on their want of evidence as to the danger from the milk of a tuberculous cow, unless her udder was diseased, has naturally been to convey the general impression that the Commission did not regard such milk as dangerous, no matter how extensive the disease of the cow in the rest of her body—an admission only too likely to be taken as a rule for universal guidance. This opinion of the Commission is confirmed by subsequent sections (1) of the report, in which the protective measures recommended relate only to milk from cows with udder disease. That the conclusion of the Commission is absolutely incorrect and the doctrine advanced upon it dangerous to the highest degree, is proved by scientific evidence, part of which was before the world long before the sitting of the Commission, but of which they appear to have had no knowledge, and part of which was published subsequently. Thus Bollinger, in 1880, produced tuberculosis by innoculation with the milk of a cow whose udder was not tuberculous; Hirschberger (1889) found milk infective from a cow affected with slight tuberculosis of the *lung only* Ernst found in 114 samples of milk from 36 tuberculous cows, showing no udder lesion, that 28.57 per cent. were infective; Smith and Schroeder found the milk infective in two cases out of six; and Delépine found the same in five out of twenty-four tuberculous cows with no udder lesion.(2)

Again: ". . . The presence of tubercle bacilli in the milk of cows that respond to the tuberculin test without showing clinical evidence of tuberculosis was proved in the same year (1899) by the thorough experiments of Adami and Martin. A further proof in support of this theory was furnished by my last year's observations on milk supplied to infants in Berlin. . . The supply of milk taken from animals . . . contained tubercle bacilli though they showed no clinical symptoms of tuberculosis." (3)

(10).—LAW IN RELATION TO TUBERCULOUS MILK.

Special powers for dealing with tuberculosis and milk have been obtained by the authorities of Glasgow, Manchester, Liverpool (4) and many other English towns. Most of these powers, as ultimately granted, are based on the findings and recommendations of the Royal Commission of 1898, and for that reason alone, and others also, fall far short of requirements. The Corporations of Manchester and several other towns "sought limited power of inspection of the cows on all farms supplying them respectively with milk; and of exclusion of milk of cows with any form of udder disease or suffering from advanced (5) tuberculosis." These proposals were modified considerably by the Local Government Board, the Board of Agriculture, and the Associated Chambers of Agriculture and finally, the Corporations in question obtained the very limited power (1) to fine a dairyman who sold milk from a cow with a tuberculous udder, or continued to keep a diseased cow among other dairy cattle; (2) to require dairymen to notify tuberculosis of the udder.

Recommendations:

1.—With regard to Milk every sanitary authority should arrange for the systematic bacterial examination, and, as far as possible, the control, of the milk supply of its district.

2.—Every dairy farmer or producer of milk for sale should, before offering such milk for sale in any district, and whenever required by the sanitary authority of such district, satisfy such sanitary authority that the cattle yielding such milk are, each and all of them, free from tuberculous disease, as proved, after the application of the tuberculin test, by the certificate of the veterinary inspector of the district in which such milk is produced.

(3) Dr. T. Rabinowitsch, Trans. Brit. Cong. on Tuberculosis, 1901. Vol. III., pages 508-9.

(4) The Liverpool Clauses are given in extenso in the Appendix to this Report. P. 51.

(5) The Sanitary Committee of Newcastle-upon-Tyne are of opinion that the word "advanced" should be omitted from the list of powers to be sought for the city.

3.—With or without suspicion of any milk or milk-product having caused or being likely to cause infectious disease, every sanitary authority should have full power:—(*a*) To inspect the cowsheds and dairy premises of any farm or dairy supplying the district of such authority with milk or a milk-product, and prevent the sale of such milk or its product in their district unless and until they are satisfied as to the sanitary condition and regulation of the cowshed and dairy premises generally in which such milk is produced; (*b*) To inspect, examine, and apply the tuberculin test to any cow; (*c*) To collect at the place of production or elsewhere such samples as they may require of the milk of any cow, the yield of which is intended for sale within the district of such authority: dairymen should be required to render assistance, and any person obstructing should be liable to penalty; (*d*) To prevent under penalty the sale of the milk of any cow re-acting to the tuberculin test, or found to be effected with any form of tuberculosis whatsoever, or any other disease of the udder; (*e*) To brand and cause to be destroyed any dairy cow re-acting to the tuberculin test; the State to compensate the owner in the event of his compliance with the requirements being approved by the sanitary authority; (*f*) To require under penalty that a cow shall not merely be brought into any sanitary district or allowed to remain therein for the production of milk for sale unless and until such cow has been recently, and within a specified time, officially tested with tuberculin and failed to re-act thereto.

4.—The limitation of the prohibition of the use of milk or milk-products of tuberculous cows to such cows only as have disease of the udder should be abandoned as mischievous.

5.—It should be the duty of every sanitary authority (medical officer of health) of a district in which milk sent there for sale from an outlying district is found to be tuberculous, without delay to report the fact to the sanitary authority (medical officer of health) of such outlying district, or the county council in which such district is situated. On receipt of such information by the sanitary authority (medical officer of health) of such outlying district it shall be their (his) duty without delay to cause the tuberculin test to be applied to each cow of the dairy at which such tuberculous milk was produced, and to cause all such steps to be taken as are indicated in the preceding par. 13, sections (d) and (e). Until the completion of such testing, they (he) should prevent the sale of any milk from the dairy in question, and should without delay inform the sanitary authority of every district ordinarily supplied with such milk, that they have (he has) done so. It should be the duty of the county council to see to the carrying out of all of the foregoing requirements, and any farmer, dairyman, etc., who, after prohibition as above indicated, sends milk or its products to any district for sale, should be liable to penalty.

Every sanitary authority should be empowered and required to license for a stated period every dairy and cowshed in their district or in any outlying district in which milk is produced and sent to their district for sale; and to require as one of the conditions of every such license or its renewal that all cows of such dairy, including new additions, be proved by official veterinary certificate, after application of the tuberculin test, to be free from tuberculosis before their milk shall be offered for sale. Any unlicensed milk dealer selling or offering milk for sale should be liable to penalty.

All sanitary authorities should be encouraged to promote, by means of lectures and addresses, the education of the inhabitants of their respective districts as to the nature and causes of tuberculosis, the measures for its prevention, and the duty of private persons and the public generally in respect thereto. The sanitary authorities of Great Britain should unite to establish a Board of Representatives as a supreme national health authority, to deal with tuberculosis and other national disease, physical degeneration, and the various matters relating to public health.

A special Council of Representatives should be appointed to consider and report on the foregoing recommendations, and the action desirable to give effect thereto.

As all sanitary authorities are equally interested in this great question, they are earnestly requested to consider and as far as possible to co-operate in carrying out the foregoing proposals.

OPERATING THEATRES.

ST. PETER'S HOSPITAL.

Partial Excision of the Bladder for Malignant Growth.—Mr. Swinford Edwards operated on a man, æt. 54 (who looked his age), who had presented himself with the following history: Two years ago he had an attack of hæmaturia which lasted two days; he had no further symptoms until April of this year, when on getting up in the morning he passed a large amount of blood and many clots. Since then he had been troubled with increased frequency of micturition (12 by day, 4 by night), and with difficulty in passing water. On admission, and up to the present time, there was always a little blood at the end of micturition. He has not complained of much pain, though there was sometimes slight pain during micturition. He did not think he was losing flesh. Cystoscopy had been performed in the out-patient department by Mr. Pardoe, when a typical epithelioma of the bladder was seen occupying apparently an area of a two-florin piece. It was situated on the anterior wall, and did not seem to involve the vesical orifice of the urethra. Urinary analysis was as follows: Cloudy; light colour; slight reddish deposit; acid; specific gravity, 1013; some albumen; no sugar; urea 1.2 per cent.; microscopical examination showed crystals of urates; there were no enlarged glands to be felt either in the groin or abdomen. The patient having been anæsthetised, supra-pubic cystotomy was performed. It was found that the incision into the bladder went right through the growth. On inserting a finger into the viscus, the extent of the epithelioma could be made out by palpation between the finger and thumb. It was found to have an area of about three inches square, and to be confined to the anterior wall and fundus of the bladder, not extending to the lateral walls. Upwards, it did not go as far as the peritoneal reflection, though there were inflammatory adhesions between the peritoneum and bladder-wall, rendering stripping very difficult. The growth itself, Mr. Edwards said, promised to remove easily. In stripping the peritoneum, the membrane was torn and was stitched up at once with a silk suture. The incision in the bladder wall was then continued upwards until clear of the growth, which last was next gradually excised by means of a pair of scissors, one blade of which was inserted into the bladder through the primary incision. The bladder wall was cut through well clear of the growth (about three-quarters of an inch) on the right side, the cut edge being clamped by a succession of artery forceps, this being repeated on the left side and in this way the growth was completely removed. There was not much bleeding, only a few vessels having to be tied with catgut ligatures The cut edges were brought into apposition before the forceps were removed, and stitched together with stout catgut which did not penetrate the mucous membrane. An aperture was left at the anterior part just big enough to admit a full-sized tube, and the skin incision was closed in the ordinary way, a smaller tube being inserted as far as the bladder-wall. The cuts necessary to remove the portions of bladder extended to within an inch and a half of the vesical orifice of the urethra. Mr. Edwards pointed out that the naked eye appearance of the growth was that of a typical epithelioma. It was a hard nodular ulcerated mass with infiltrated edges, but the extent of growth in the bladder wall did not seem to be much greater than the area of ulceration. No evidences of lymphatic infection were found during the operation. Mr. Edwards remarked that this operation was a very rare one on account of the inaccessibility generally of malignant growths of the bladder. It would be found, he said, that in the vast majority of these the disease was situated around one of the three orifices of the bladder, namely, the two ureteric openings and the orifice of the urethra, so that, as a rule, in malignant cases, the fundus of the bladder was chiefly involved. He had only had one previous case in which a small carcinomatous nodule was excised from the anterior wall of the bladder. In the present patient he had found the growth larger than he had anticipated would be the case judging from its cystoscopic appearance. It practically necessitated the removal of the whole anterior bladder-wall from the apex to within an inch and a half of the urethra. With regard to the operation, the patient was placed in the Tredelenberg position, as soon as the bladder contents had been evacuated. The usual supra-pubic incision was made, but in order to give sufficient access to the field of operation, it was found necessary to divide the inner fibres of the recti on each side. He regretted having inadvertently opened the peritoneal cavity whilst stripping the serous membrane off the bladder, but owing to the peritoneum being tightly bound down in the neighbourhood of the tumour, it was unavoidable. However, it was fortunate he at once recognised this *contretemps*, and took care to repair it before incising the bladder. At the end of the operation a small tube was inserted down to, but not into, the bladder. Mr. Edwards said that there were very few cases of excision of portions of the bladder for malignant growth on record, and he believed that recurrence had taken place in a considerable proportion of the small number recorded In the present case, he hoped for a better result, owing to the free removal of bladder-wall with the tumour, and also because of the fact that there was no apparent enlargement of glands or lymphatics.

A month aftert he operation the patient is passing all his urine per urethram, and the supra-pubic wound is firmly closed. The man himself is in a very satisfactory condition.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, Aug. 4th, 1907.

At the German Society for Surgery, Hr. Thorkild Rovsing read a paper on

Total Extirpation of the Urinary Bladder with Bilateral Lumbar Ureteral Openings.

He observed that total extirpation of the bladder was only rarely performed, although it was frequently indicated with propriety, this was on account of its appalling immediate mortality. Of 31 cases operated on 51 died—a mortality of about 50 per cent. (17 males with 11 deaths—64.7 per cent.; 11 females with 4 deaths—36 per cent.). This high mortality could not be dependent on the dangerous nature of the operation itself, as it could be mostly performed without much hæmorrhage, and without any special difficulties, but the difficulty lay rather in treating the severed ureters in such a way that infiltration of urine and infection of the large, deep wound was avoided. Hitherto the ureters had been chiefly treated in three different ways: (1) opening freely into the wound (Bardenheuer, Kuemmell); (2) into the rectum or the sigmoid flexure (Maydl, Tuffier, Modlinsky, Kuemmell, Krause, Hogge, Wilms); (3) in females by implantation into the vagina with subsequent colpocleisis (Pawlick).

By the first method infiltration of urine was of course unavoidable, with the second, opening into the rectum always gave rise to danger of infection. If the sutures cut through, urine mixed with fæces emptied into the wound, and even where the case ran an ideal course the danger of secondary ascending infection was always to be feared. Vaginal implantation involved castration, incontinence generally resulted and there was also a danger of ascending infection. The speaker had therefore hit upon another way, as he came upon a case of bladder tumour where total extirpation seemed the only way of saving the patient. At the one sitting he performed bilateral lumbar ureterostomy. As his success in this as well as in two later cases exceeded his expectations he believed he was justified in describing his method and recommending further trials.

Under æther and in the Trendelenburg position a wide semi-circular incision with the convex part downwards was made just above the symphysis with partial separation of the insertions of the recti muscles, and the bladder was reached. This which was previously filled with a 1 per cent solution of phenosalyl was now opened, separated from its surroundings like a cystic tumour—in males along with the prostate—and finally removed, after the urethra had been drawn out like a pedicle, and cut through between two pairs of clamp forceps. In two cases he succeeded in enucleating extra-peritoneally, in one the peritoneum was attached and infiltrated with carcinoma. Here the whole peritoneal covering was also removed, and after the completion of the extirpation the large peritoneal wound was closed by a running Kuerschner suture. The wound cavity was tamponnaded with gauze moistened with a 1 per cent. solution of silver nitrate. The recti muscles were again attached, the skin wound was sutured with aluminium bronze, up to the middle line where a strip of gauze was left in. The ureters were then sought through small oblique lumbar incisions, freed as far as the ligatures and drawn out completely so that they hung out of the lumbar openings like two earth worms. The lumbar wounds were then at once closed and covered with collodion and lint. The ureters were then placed in a symmetrical position in the trigonum Petiti, conducted into a sterilised glass container after a No. 12 catheter had been introduced into the ureter beyond the abdominal walls. Outside the ureter was drawn through a perforated rubber cap and protected by it. The ureter now healed in and necrosed up to 2-3 cm. and projected above the skin as a small beakshaped urethra when the necrosed part was cut off in about a week. When the lumbar incisions were healed the catheters were removed from the ureters and from then the urine was cared for by dressings. These dressings (made by Svensen and Hagen, Copenhagen) consisted of a wide elastic binder into which two plates of silver were sewn, each provided with an opening into which the flat silver flasks that collected the urine accurately fitted Flattened silver tubes ran from these to which india-rubber tubes were attached which conduct the urine into a urinal hung below the symphysis. On the under surface of the silver capsule is a rubber ring filled with air which is pressed on by the girdle round the loins. The apparatus had proved its usefulness as the patient first operated on had been able to keep dry day and night for a period of eleven months. The speaker demonstrated the apparatus and also the three malignant tumours removed. He also related the cases in detail, and claimed that the operation could be performed without danger of sepsis or of dangerous infiltration of urine.

AUSTRIA.

Vienna, Aug. 4th, 1907.

Experimental Cirrhosis and Tubercle.

Stoerk reported a few experiments he has made with tubercle to the Gesellschaft. He found that all the animals which were infected with tuberculous matter produced changes in the liver resembling cirrhosis. This transition took place irrespective of virulence or nature of the bacilli. The changes usually commence in the remote or finer ramifications of the blood-vessels in fibrous bands that increased in the opposite direction to the blood current, *i.e.*, from the capillaries towards the larger arteries. The specific epithelial tissue is first changed into a cellular tissue that subsequently passes in to a hard fibrous tissue traversed by the gall ducts. He believes that many cases of cirrhosis are due in the first instance to tubercle and not always to external poisons from excess, &c.

Inguinal Glands and Tubercle.

Bartel demonstrated from a few preparations taken from guinea-pigs into which he had injected tubercle. The first example was a right-sided inguinal lymphatic after subcutaneous tuberculous infection by vaccination The gland was seen to be hard and fibrous with a few isolated giant cells. The second animal had large cicatrices in the lung with bronchiectasis. Three and four animals had been fed, one with infected food, the other with pure food, but vaccinated copiously. The former suffered severely from tuberculosis and was treated for the disease while the vaccinated animal suffered very little. From this he reasoned that there was more danger from food than even vaccination, while breathing was inoffensive. Number five animal by vaccination showed a large quantity of eosinophile cells, enclosed in hard centres in the lungs.

Tar and Nephritis.

Swoboda showed a young girl, æt. 4, who had suffered from nephritis, the result of using a tar ointment for a troublesome eczema. This case seems to be one peculiarly averse to the drug as not more than 30 or 40 grammes at the very outside was used in the treatment of the eczema. The ointment used contained 3 per cent. of the tar product. In the ordinary text-books we are taught to apply large quantities of this substance without any qualifying restraint, not less than 5 or 10 per cent. when administered to young children. This is a mistake. Prescribers should be warned of the danger that lurks in the drug when freely used.

Escherich presumed that the active principle, terebene, was copiously absorbed by the open eczematous wound, which speedily produced the toxic effects recorded.

Schessinger thought the disposition of the patient had more to do with the toxic results in these cases as large quantities of the tar products can be used in open wounds without the slightest symptom of any malaise.

Physiological Lines on Nails.

Schick treated the members to an exhaustive history of the lines on the nails of children. Besides the inflammatory paronychia of syphilitic infants there were physiological lines, due probably to gastric or intestinal catarrh; but such transverse lines are also found in perfectly healthy children where no catarrh exists. About the end of the fifth week a wavy transverse line may be observed on the thumb of the infant, but sometimes appearing first on the fingers, with the convex margin towards the point of the digit, from which it recedes about the 90th day. As a rule these lines appear first in the thumb, and pass along to the little finger in regular sequence. This change has been designated a physiological one, but correctly speaking it is just as pathological as the syphilitic marking. It would appear that this so-called physiological marking of the nails is due to the injury done to the organism when it is passing from the intra to the extra-uterine life. This is supported by the fact that the weight of the child falls during the first week with the well-known physiological desquamation.

Hochsinger said he had often observed this phenomenon when looking for the syphilitic marking during the exanthematous period. Schick's physiological marking was quite distinct from the syphilitic in point of time, the latter being always later than the former.

Swoboda had long observed this linear pathological change in scarlet fever, he said, as well as in other severe diseases.

Escherich thought this marking was due to the disturbed balance in the metabolism after birth.

LETTERS TO THE EDITOR.

THE GENERAL PRACTITIONER.

To the Editor of The Medical Press and Circular.

Sir,—At the recent annual meeting of the Parents' Union I was much impressed by some passages in an address by the Hon. E. Lyttleton, Head Master of Eton. He described as really tremendous the fact that the three great altruistic professions, the ministry of the gospel, the medical, and the teaching professions "are all being starved." He declared it as his conviction that this is principally because we are passing through a phase of believing that excitement, and amusement, and comfort are ends of living instead of very dubious concomitants. He said that thousands of men outgrow the belief; but by the time they do, their professional career in life is fixed, and it is not altruistic or social, because another amazing lie has been somehow stamped upon the minds of the youth of to-day, viz., that social service is dull. If I quote the substance of these passages it is not to express agreement with the idea that the medical profession is being "starved" in the sense that Mr. Lyttleton uses the word. Every general practitioner, at any rate, knows that there are more doctors than are called for. What I want to bring forward and emphasise is the fact that no one should take up the calling of medicine unless he has more than the average of capacity for self-sacrifice. He ought to love science, to love his profession, and have an unlimited amount of sympathy with suffering humanity. If he has a keen sense of humour, and an optimistic temperament, the outcome of sound physique and health, so much the better; and if, along with these intrinsic endowments he possesses at the outset so much of the world's goods as puts him beyond the risk of grinding poverty, his life as a doctor in whatever rank he may find himself ought to leave little real cause for complaint. To practise medicine as a trade, as a mere money-making routine employment, must be always more or less degrading; whilst to pursue such a trade with the sole aim of money grabbing, with the aim first of all of getting as much money as possible out of every patient instead of subordinating every thought to consideration of the welfare of the patient, is to demoralise oneself below the level of the lowest trade trickster of the day. An unqualified quack may sometimes plead ignorance, but no such excuse can be urged by an educated professional man. Men who make money in such a way are not to be envied, they themselves probably always come to recognise that peace and happiness are not to be achieved by such methods. Whilst a doctor must be prepared for a hard life there seems no reason why he should not demand from the State the privileges and the protection, which are his just due. To gain these, I agree with your correspondent G. P., he must combine, and with one voice demand and insist upon his rights. The general practitioner at present seems sadly in want of leaders to guide him in this direction.

I am, Sir, yours truly,

August 1st, 1907. G. P. *No.* 2.

To the Editor of The Medical Press and Circular.

Sir,—I am much interested in the correspondence now going on in your esteemed columns with regard to that despised individual, the G.P. The general practitioner doubtless has his misfortunes and makes his mistakes—like a few consultants—but he has, be it remembered, about ten specialties to keep going all at once, which is rather a strain on a "ranker," when the "officer" finds one as much as he can manage. I have had in twenty-four hours to go from a placenta prævia case (with which I was up all night, and saved the mother, but not the child) to an accident in a mine, and deal with five cases of various kinds of fractures and severe wounds; then drive on to a bad prostatic case with retention of urine in an important county gentleman, and from there to consult with a brother practitioner in a doubtful case of small-pox! Thank heaven, I don't have such days every day, but it shows what we G.P.'s may have to do. Happily, I do not know a tubercle bacillus by sight from a cod-fish, and I have, I confess, a bit of Mr. Bernard Shaw's contempt for the opsonic index, and I think most of my assistants soon get that stuff knocked out of their heads when they find themselves with their first shoulder presentation, or strangulated hernia. If our "pastors and masters" would come down to a rough colliery practice for six months, the medical curriculum would soon be chopped up into something very different.

I am, Sir, yours truly,
Collier.

P.S.—I never read The Medical Press and Circular without finding something in my line, though I always skip the opsonic index, and all that.

To the Editor of the Medical Press and Circular.

Sir,—I have been much interested in the two letters published in this week's issue of your paper and am obliged to the writers of both for their kindly references to me. The works which Dr. Edwards alludes to show that he has given much thought to one need that I emphasised, namely, good text books written to supply particular information for the general practitioner, and with his remarks I am in complete sympathy. But the other aspect of the problem that G.P. draws attention to is a not less important one. How are we to overcome the apathy of the general practitioner, so that he may realise more clearly what is required to improve his own position?

My aim has been to point out that it is for the good of the medical profession *as a whole* that the ordinary medical man should be better represented. That there are many aspects of health and disease of which he alone has experience, and that he cannot be expected to make use of his research opportunities till he is better supplied with literature, has greater leisure, and some pecuniary compensation offered to him for labour honestly expended. It is this *whole* outlook I would ask other medical men to bear in mind. There is widespread discontent felt with the unsatisfactory state of general practice. The fault is, as G. P. remarks, largely our own. When the apprenticeship system was abolished the student lost touch with the conditions of ordinary medical experience, and the improvement in the skill of the practitioner himself caused the consultant to cease his, at one time, customary supervisory control. These two developmental factors have almost separated the general practitioner's outlook from the consultant's and the specialist's, and it rests with him to show how a return to medical unity on a higher plane can be brought about.

I would personally welcome any suggestions or criticisms of real or apparent weaknesses in the position here laid down.—I am, Sir, yours truly,
J. Lionel Tayler.

Willesden Green, N. August 2nd, 1907

Mr. A. Pearce Gould, F.R.C.S., has received a donation of one hundred guineas for the Cancer Research Fund of the Middlesex Hospital from Mr. A. J. R. Carlill.

OBITUARY.

JOHN PIRIE, M.A., M.B.Aberd., F.F.P.S.Glasg.

We regret to record the death of Dr. John Pirie, late of Glasgow. Some years ago, Dr. Pirie retired from the practice of his profession in that city, and went to reside at Courthill, Campbeltown, where he passed away on July 24th. Dr. Pirie, who had reached his 81st year, was a native of Ross-shire. He was educated medically at Aberdeen University, where he took the full Arts course, graduating M.A., and afterwards his M.B. degree in 1851. In 1868, he became a Fellow of the Glasgow Faculty of Physicians and Surgeons. His first appointment was as house-surgeon in the Aberdeen Royal Infirmary, and about the year 1852 he went to Campbeltown, where he remained till 1867, when he came to Glasgow, and there the rest of his active life was spent. Dr. Pirie was a fine representative of the physician of the old school, genial, kindly, and generous, with a rich fund of wit and humour. By his professional brethren he was held in the highest respect, he had the confidence, in many instances the warm affection, of his patients, while he had the regard and esteem of all who had the privilege of his acquaintance. From the time he came to Glasgow he took a great interest in the necessitous poor, and, along with Dr. W. L. Reid and a few kindred spirits, he founded the Glasgow Medical Mission, one of the most beneficent of the institutions of the city. He took a warm interest in everything connected with the Highland counties, and he was at different times president of the Kintyre Club, the Ross and Cromarty Society, and the Northern Highland Benevolent Society. He is survived by three sons and one daughter.

SPECIAL ARTICLE.

ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

Exeter, July 27th to August 3rd, 1907.

[From Our Special Correspondent].

The Exeter Meeting has proved an unqualified success. Good weather, numerous visitors, unbounded hospitality, well-ordered meetings, interesting sectional discussions, an exceptionally excellent pathological museum, a good trade exhibition, and many attractive entertainments, social gatherings and wisely selected excursions have all united to crown this year's great Conference of Medicos with distinction. To the President and his *confreres* and many friends and helpers, and also to the permanent officials of the Association, congratulations and thanks are due.

Next year's gathering in the smoke-laden city of Sheffield will not easily surpass the success of the quiet and quaint cathedral centre of the West.

The Business of the Association.

The scientific visitor and the mere perfunctory medico know little of the strenuous work of the Council and representatives. Under its new constitution the Association is slowly finding its feet and testing its powers. As yet, however, it can hardly be said that this large and influential body has come into its kingdom. This year, however, good progress has been made. In the near future important advance will be made in several directions. The rapidly progressing new Central Offices in the Strand will prove of much service in aiding the fit and proper evolution of the Society.

Dr. H. Radcliffe Crocker, has tendered his resignation of the important position of treasurer, and Dr. Edwin Rayner, of Stockport, has been elected his successor. Dr. Smith Whitaker, the indefatigable Medical Secretary, is to receive further assistance, so that the work of his department may be more adequately dealt with. The financial position of the Association received much consideration, and steps are to be taken to extend and consolidate this essential factor. Much time was also devoted to the old perplexities and ever recurring puzzles relating to the relationships of patients, practitioners and consultants, hospital abuse, and medico-political procedure and legislative action touching medical practice and the interests of the sick, and the progress of sanitary science.

Official Addresses.

The President's Address on "Science in its Application to National Health" was received with general approval, and was certainly timely in its strong expression of the need for a national awakening to the importance of physical culture and the urgent necessity for a Government inquiry into the widespread scourge of tuberculosis which is working such loss to us as a people.

Dr. W. Hale White's address on "Medicine" was an eloquent plea for accuracy of thought and a worthy sermon on the righteousness of confession of ignorance, limitation of knowledge and the wisdom of recognising an effort-making agnosticism in matters medical.

Mr. Henry T. Butler's address on surgery was an able and impressive oration on the contagiousness of human cancer, in which he presented evidence that auto-inoculation, though rare, did occur, and thus opened a view to the pathology of malignant disease which had far-reaching practical bearings.

Sir John William Moore's popular lecture on "Weather, Climate and Health" was a well-ordered exposition of man's relationship to various natural conditions which exercise profound influence on the maintenance of health and the production of disease.

The Work of the Sections.

The chief work of the meeting was conducted in the Sections, thirteen in number. Most of these were attended by comparatively only a few enthusiasts, but many valuable and interesting discussions took place, and not a few suggestive papers were presented. The present arrangements for the conduct of the work of the sections leave much to be desired and, evidently, if the scientific value of the annual meeting is to be maintained, close attention should be given to this most important matter. As a first step a time-table should be arranged for each section and rigorously adhered to. Communications should, as far as possible, be of the nature of demonstrations, and all papers should be printed in full or in abstract form before presentation. By these and other improvements in selection and procedure the scientific work and service of the sections would be considerably increased and enhanced.

Among the numerous discussions which took place, and papers which were presented, it is, in the limits of space at our disposal, impossible to refer to any in particular. We are, however, arranging to give abstracts of the more important in our pages during the next few weeks.

Entertainments.

Carping critics are wont to sneer at an annual gathering such as this as little more than a proceeding of "picnicking," and for not a few of the visitors this, t must be admitted, is the most manifest feature. But even a general practitioner is worthy of a holiday, and there seems no adequate objection to associating social pleasures with scientific pursuits. Exeter has, at all events, succeeded in accomplishing this pleasing Union. During this week numerous attractive entertainments have taken place. The Mayor and the Sheriff (Dr. Picard) extended a civic welcome to the visitors and received them in the ancient Guildhall. The Mayor and Mayoress (Alderman and Mrs. W. H. Reed) also gave a garden party in the pleasant grounds of Northcoutray. The President and members of the South-Western branch gave an Evening Fete. A particularly attractive garden party was given by the Lord Bishop of Exeter and Mrs. Robertson in the charming garden of the Palace.

Numerous garden parties, receptions, entertainments, were given, and many most enjoyable private luncheons and dinner parties held, and much courtesy and kindness displayed by many in guiding to local features of interest.

During the week a number of excursions were arranged for to some of the many charming places in the neighbourhood.

On Saturday, the closing "off" day, long excursions took place to Plymouth, Falmouth, Endsleigh, Ilfracombe, and Bideford and Clovelly, after which many visitors continued their delights by extending their holiday and touring into Devon and Cornwall.

The Annual Exhibition.

The "Trade Show" is always an interesting and instructive adjunct, and this year it was excellently housed in the convenient and readily accessible Victoria Hall in Queen Street, near to the Central Reception Rooms. The organizers had succeeded in presenting a thoroughly representative and well-arranged display of all varieties of "material" required for hospital equipment and the conduct of the healing art. The exhibition was well patronised and exhibitors appeared satisfied with the interest evinced by the numerous medical visitors, who, on their part, seemed pleased with the courtesy shown to them and the many and excellent arrangements which had been made for their comfort.

Ninety-one different firms had stands, and many were large and elaborate. Old favourites were conspicuous and many familiar faces were to be seen. Surgical appliances and hospital equipments were particularly well represented.

Down Brothers, Ltd., showed new and original designs for operating-tables, and a large selection of surgical instruments and anæsthetic apparatus and medical accessories. **The Holborn Surgical Instrument Company** exhibited various admirable sterilizers and several ward and instrument tables and a large collection of goods of excellent workmanship at remarkably low prices. **Messrs. Arnold and Sons** had a large and inspiring show, including the high pressure steam sterilizers, as suggested by Mr. W. Bruce Clarke. Also a large assortment of modern instruments employed in surgery, gynæcology, and the surgical specialities. **S. Maw, Son, and Sons** displayed representative types of their aseptic furniture, and of their many special surgical instruments and medical sundries. **John Weiss and Son, Ltd.**, had a large collection of ophthalmic instruments and selections of their most recent general instruments. **Thomas Hawksley** had a very attractive stall at which were demonstrated the use of blood pressure apparatus and other physiological instruments employed in clinical investigations. **Mayer and Metzler** were well represented, and exhibited many forms of instruments used in the practice of laryngology, rhinology, and otology, which well demonstrated the favour in which this firm is held for this most important and delicate class of surgical inventions. **The Equipoise Couch Company** gave practical evidence of the serviceability of their ingenious and admirable equipoise beds, lounges, and chairs. By the adoption of this system, patients may be placed in any position without trouble or exertion. This method of construction should have wide application to the needs of patients both in hospital and private practice. **Geo. Gale and Sons** had a good display of their "Lawson Tait" bedsteads, wire mattresses, and well-designed and strongly constructed hospital furniture.

Allen and Hanbury, Ltd., as usual, had a particularly attractive stand, with many new forms of instruments, transfusion apparatus, operating tables, sterilizing apparatus, and such novelties as Stack's portable dressing sterilizer and Dr. F. C. Eve's cerebro-spinal manometer. **The Liverpool Lint Company** and the **Sanitary Wood-Wool Company, Ltd.**, had useful displays of their well-established antiseptic dressings and other preparations. PHILIP HARRIS AND CO., LTD., exhibited several forms of drug, bacteriological and urinary cabinets, and a particularly serviceable and cheap form of surgery couch. REYNOLDS AND BRANSON, LTD., showed ambulance requisites, a new form of apparatus for the administration of oxygen and many ingenious appliances for clinical work. MESSRS. BROWNE AND SAYER displayed their ideal inhaler, and other hospital requisites. THE AJAX SANITARY COMPANY'S exhibit attracted much attention, being a simple and effective device for lavatory basins, sinks and baths, consisting of a sliding valve or shutter which can be made of any shape and of a variety of materials in a recess at the back of the basin, forming a moveable weir, over the top of which the waste water may run away faster than it can flow into the basin. THE MEDICAL SUPPLY ASSOCIATION presented an elaborate display of their hospital furniture, surgical instruments and dressings, anæsthetic apparatus and electrical appliances. THE DOWSING RADIANT HEAT COMPANY demonstrated their now familiar appliances for radiant heat and light treatment. G. H. NEAL showed his well-known "Repello" and other forms of clinical thermometers..

Electro-medical apparatus was well represented and admirable exhibits of thoroughly up-to-date X-ray high-frequency and electro-therapeutic outfits were made by such well-known firms as Messrs. Harry W. Cox, Ltd., W. Watson and Sons, Marconi's Wireless Telegraph Company, Ltd., Alfred E. Dean, the Sanitas Electrical Company, Ltd.

Drugs, of varying therapeutical value and in almost infinite pharmaceutical form, were exhibited by a large number of firms.

THE DENVER CHEMICAL MANUFACTURING CO. made a prominent show of their useful local application *Antiphlogistine.* THE BAYER COMPANY, LTD., reminded us of the value of such well-established agents as asperin, neroni, tannigen, veronal, and somatose. FAIRCHILD BROS. AND FOSTER made a good display of their "Fairchild Products"—peptogenic milk powder, pepsenica, panopepton, trypsin, noladin, &c. PARKES, DAVIS AND CO., as usual, were well to the front, showing elegant preparations used in modern therapy, including adrenalin, eudrenine, formidine, veratrone, and specimens of their admirable "Glaseptic" nebulisers and sprays. MEISTER, LUCIUS AND BRUNING, LTD., exhibited a selection of antitoxins, serums, &c., including the various tuberculin preparations, and a large assortment of their many synthetical preparations. Novocain and the demonstrations of its methods of employment for anæsthesia attracted considerable attention. THE MALTINA MANUFACTURING CO., LTD., made a bold show with their many and varied "Maltine" preparations. OPPENHEIM, SON AND COMPANY, LTD., showed their ingenious and acceptable "aseptules," "coccoids," and other specialities including their well-known vaporiser and aeriser. THE ANGIER CHEMICAL COMPANY, LTD., again reminded us of the benefits of their petroleum emulsion, and their more recently introduced throat tablets. THE CHARLES H. PHILLIPS CHEMICAL COMPANY exhibited their famous antacid "Milk of Magnesia," a preparation we have long approved and recommended.

ARMOUR AND COMPANY, LTD., well known for their reliable preparations of digestive ferments showed samples of their animal products. Stovaine, one of the new local anæsthetics, was shown by LES ETABLISSEMENTS POULEINE FRERES.

EVANS, GADD AND COMPANY, LTD., made an elegant display of their standardised products, including their Liq. Violæ Glucosidi, Tinct. Digitalis, and Liq. Thymo-Antiseptic Co.

THE SANITAS COMPANY, LTD., had a large show of their ever growing "Sanitas" preparations. JEYES' SANITARY COMPOUNDS CO., LTD., also displayed their "Cyllin" preparations. WYLEYS, LTD. exhibited a selection of their Neroin compound, liquors, medicinal syrups and other well-established and much valued preparations. KNOLL AND CO. showed bromural, styptol, santyl, styracol, and diuretin. The MIOL MANUFACTURING CO., LTD. made a particularly attractive show with their new "Miol," a preparation of olive oil and malt, which we have found of much value as a nutrient, particularly for children.

B. KUHN AND COMPANY exhibited the well-known disinfectant, "Chicnosol," papain and the now popular local anæsthetic ethyl chloride. C. J. HEWLETT and SON displayed their elegant pharmaceutical preparations and several useful forms of antiseptics.

Foods and dietetic preparations, both for the healthy and the sick, the infant and the adult, this year, as in former exhibitions, bulked largely, and their representatives showed no lack of enterprise in advocating the merits of their particular products.

THE AYLESBURY DAIRY CO., LTD., exhibited their new preparations, pollyta and humanoid and also showed various preparations of humanised milk, poumiss and keptin.

MELLIN'S dietetic preparations for infants and invalids were much in evidence, including their "Lacto," food biscuits, and chocolate.

NESTLE'S AND ANGLO-SWISS CONDENSED MILK COMPANY displayed specimens of their milk and milk-chocolate preparations. CADBURY BROTHERS, LTD., and J. S. FRY AND SONS, LTD., furnished liberal samples of their world-famed chocolate and cocoa preparations. INTERNATIONAL PLASMON, LTD., furnished evidence of the manifold advantages and varied forms in which Plasmon can be advantageously employed. Horlick's Malted Milk also found a place. "Virol" was prominent, and the LIEBIG EXTRACT OF MALT COMPANY, LTD., had a specially attractive exhibit of Lemco, Oxo, and other meat preparations.

KEEN, ROBINSON AND CO., LTD., presented the far-famed and old-established Robinson's Patent Barley and Patent Groats and Colman's Sinapisms and other mustard preparations.

A new casein preparation was exhibited by the well-known biscuit manufacturers, MESSRS. PEEK, FREAN AND CO., LTD., called "Tilia," in the form of biscuits, which is likely to become very popular in the near future.

CALLARD AND CO. presented their starchless and sugarless preparations which have done so much to simplify and render palatable the dietary of diabetic and other cases. THE MANHU FOOD COMPANY, LTD., also showed their diabetic foods. G. VAN ABBOTT AND SONS exhibited preparations of their Gluten bread and other foods for diabetics and obesity cases.

THEMHARDT'S FOOD COMPANY, LTD., showed their useful soluble food for infants and their palatable and nutritious "Hygienia." Reynolds' Pure Digestive Wheatmeal and Wheatmeal Bread was prominently displayed. VIROGEN, LTD., exhibited their "Virogen" and other foods. BROOMFIELD AND CO. again showed the useful vegetable fat "Albene."

RONUK, LTD., had a stand on which were set out their various wood stains and sanitary polishes.

THE CELLULAR CLOTHING COMPANY, LTD., showed their excellent "Aertax" clothing, which we can thoroughly recommend from personal experience.

Beverages found a prominent place. Such favourite waters as Perrier, Apenta, Apollinaris, Johannis. ALEXANDER RIDDLE AND CO., LTD., and FELTOE AND SMITH, LTD., presented their lime-juice and lemon preparations. CAMWAL, LTD., reminded medical visitors of its numerous aerated mineral waters, which are particularly fine and palatable.

Friedrichshall, the old-fashioned but valuable natural aperient mineral water, made a praiseworthy bid for a renewal of its ancient and well-merited popularity.

INGRAM AND ROYLE, importers of many forms of natural mineral waters, supplied useful information concerning their particular specialities. Several health stations availed themselves of the opportunity of making known their special climatic and other advantages. Buxton furnished information concerning its mineral waters and baths. Harrogate furnished attractive literature concerning its many means of providing all forms of hydro-therapy in its Royal Baths.

The Borough of Royal Leamington Spa also furnished a stall with literature concerning its special climatic advantages and bathing establishment.

Several medical publishers wisely gave opportunities to country and busy practitioners to examine their books. Among those exhibiting were H. K. Lewis, W. B. Saunders Company, Rebman Ltd.

The Pathological Museum.

All concerned in the preparation of this year's pathological collection merit congratulation. The selection and arrangement of preparations were excellent. Unfortunately, the Barnfield Hall, in which the specimens were laid out, was somewhat out of the way and was not visited, we fear, by many except those specially interested. An excellent catalogue made the collection one of the most valuable and instructive features of the meeting. It consisted of 139 pages of descriptive letter-press, giving descriptions of over 900 specimens, photographs, drawings, &c. A particularly praiseworthy feature were the demonstrations given on three mornings by Mr. Ernest N. Shaw, Dr. F. W. Mott, and Dr. W. F. Bashford.

Where almost every exhibit is worthy of thorough study, it is difficult and appears invidious to particularise. Special interest, however, centred about the extensive collection of specimens illustrating diseases of the breast, lent by St Bartholomew's Hospital; preparations illustrating the researches carried out by the Imperial Cancer Research fund under the direction of Dr. Bashford; the diagrams of Professor Ehrlich, illustrating experimental tumour production, and the very extensive collection of specimens illustrating tropical medicine and parasilology.

The preparations of cerebro-spinal meningitis, sent by Professor Muir from Glasgow, were of special interest and value.

Professor Strassmann, of Berlin, furnished a particularly beautiful series of gynæcological preparations, the mounting of which were beyond praise and admirably adapted for teaching purposes.

Among the special exhibits were series of specimens exemplifying lesions of the Brain and Spinal Cord, and the Liver and Gall-bladder. The large collection of X-ray photographs of fractures near joints and dislocations were of great value to surgeons.

Dentists found a special section devoted to preparations illustrating dental pathology, arranged and classified by Mr. W. H. Yeo.

A department which might well be developed to larger dimensions in future was that displaying instruments for pathological investigation. We should like to see every year a complete exhibit of all new instruments for clinical research.

It seems lamentable that a collection so valuable, and entailing the expenditure of so much time and trouble should be available for so short a time, and should be seen and studied by so few.

It is certainly worth considering whether it would not be of greater service to medical science if the annual pathological museum could not be held in London, and allowed to remain open for at least a month.

This year's collection is so excellent that we think it should support the suggestion which we have ventured to make.

REVIEWS OF BOOKS.

JONES' MEDICAL ELECTRICITY. (*a*)

The rapid issue of edition after edition of Lewis Jones' "Medical Electricity" proves that the work is found useful by medical readers. The present edition contains new matter, such as the use of mechanical means for obtaining interrupted currents of measured duration; the introduction of drugs by electrolysis; the treatment of rodent ulcer by zinc ions; the treatment of skin diseases by X-rays, and so on. The mere recapitulation of these additions reminds us of the rapid strides that are being made in electrical therapeutics. Perhaps one of the most interesting things to note in this connection is the number of skin conditions that are invaluable to modern methods. Lupus of the nasal cavity, for instance, may be attacked with a high frequency electrode; warts may be cataphoresed with magnesium sulphate; xanthelasma of the lids speedily cured by electrolysis, while mycosis fungoides often disappear beneath the X-rays. Dr. Lewis Jones' book contains a great amount of material, which is conveyed to the reader in good literary style. A vast deal of accurate and condensed knowledge is contained therein, and we have every confidence in recommending this work. There is an ample X-ray section and many illustrations.

McCONNELL'S PATHOLOGY. (*a*)

This little manual fills a useful position in the literature of the subject. A wide range of knowledge is covered by the author, who presents his information, in some instances, in the shape of a series of short notes, and in others by a fuller description. The matter, so far as we have tested it, is accurate and up-to-date, such as one would expect from a teacher of the author's experience. There are many excellent illustrations and several coloured plates. In this unpretending volume Dr. McConnell has provided the busy practitioner with an excellent condensed reference book on pathology.

THE GEM CUTTER'S CRAFT. (*b*)

This work, from its title, might appear to be of too technical a charater to be interesting to the ordinary reader apart from those actually interested in gems from a business point of view. A careful perusal has, however, convinced us that it will appeal to very many, both at home and abroad, on account of the highly interesting and attractive manner in which the author has handled his subject. Although a master of his craft he has contrived to make a most readable book and one, too, that while not burdened with over-many technical minutiæ seems to contain most of the information that can be required even by those who make the discovery, mining, and preparation of gems their particular business. In his brief preface the author says, "I do not address myself especially to the jeweller, the miner, the collector, the lapidary, or the amateur, but that my book may prove of interest and assistance to some of these I sincerely trust."

There is no doubt whatever that the author's expectation will be fulfilled, and we hope also that the book will find a place in the libraries of many who do not come into the classes he enumerates. The history of certain famous gems and of gems generally is given, and the curious fancies and superstitions of the ancients regarding some of them. The methods employed for their recognition and the details relating to their preparation (cutting, polishing, etc.), are given in detail. The wealth of illustrations and the excellent manner in which they are reproduced add an interest which could hardly have been conveyed by words alone. Although there are so many (almost as many as there are pages in the book) no one of them can be regarded as "padding," and the letterpress and the illustrations separately are each well worth the price charged for the book.

The publishers have done their share well, the print, paper and binding combine to make the work a creditable addition to any library.

(*a*) "Medical Electricity." By H. Lewis Jones, M.A., M.D., In charge of the Electrical Department in St. Bartholomew's Hospital, &c. Fifth Edition. London: H. K. Lewis. 1906.

(*a*) "A Manual of Pathology," By Guthrie McConnell, M.D., Pathologist to the St. Louis Skin and Cancer Hospital, &c., &c. Philadelphia and London: W. B. Saunders and Co. 1906.

(*b*) "The Gem-Cutter's Craft." By Leopold Claremont, Author of "A Tabular Arrangement of the Distinguishing Characteristics and Localities of Precious Stones," in the *Mining Journal*. London George Bell and Sons. 15s. net. 296 pp. 259 illustrations.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for The Medical Press and Circular.

RECENT PATHOLOGICAL LITERATURE.

Treatment by Bacterial Inoculation.—Whereas the "boom" in vaccine treatment which followed on the publication of Wright's discoveries some two years ago has undoubtedly died down, and vaccines are not used as widely as they were a year ago, nevertheless signs are not wanting that the vaccine method is taking its legitimate place in treatment, and that physicians and surgeons recognise better than they did the kind of cases to which it is suitable. One need of the present situation is that practical workers should regularly make their results known—whether successful or the reverse, and that thus the profession should be put in the way of estimating the true value of the treatment, and of learning the rules which govern its applicability. A particularly valuable paper in this respect is that of Von Eberts and Hill (*American Journal of the Medical Sciences*, July, 1907). In other respects it will be of use to practical workers in that it furnishes many hints on technique, and on the fallacies which may interfere with accurate opsonic estimation. (1) Full instructions are given as to the preparation, standardisation and dilution of vaccines for inoculation purposes. The authors advise that if the best results are to be obtained, the vaccine should be derived from the actual infecting organism of the individual case. This rule, however, does not always apply. Thus, they hold that in streptococcic infections, the personal vaccine is a necessity, and in acne a personal vaccine gives the best results. On the other hand, in furunculosis and carbuncle heterogenous vaccines are often satisfactory, and in gonococcol and meningococcol infections the authors look for the best results with heterogenous vaccines. In working with tubercle, they are in the habit of using Koch's T. R., carefully diluted, but they have devised a method of preparation of personal tuberculin. (2) They furnish notes of fourteen cases treated—tuberculous ulceration of bladder, lupus, tuberculous arthritis, tuberculous adenitis, furunculosis, carbuncle (*two*), suppurative periostitis, multiple abscess, acne, gonorrhœal polyarthritis, epidemic cerebro-spinal meningitis (*three*). In all the cases except one of meningitis, which ended fatally, there was either a complete cure or a marked improvement. The notes on the cases emphasise the authors' remarks on the respective value of personal and heterogenous vaccines; (3) The authors state their views as to the supposed necessity for constant estimation of the opsonic index during treatment. They say: "While the opsonic index is a most valuable guide in regulating the amount and time of dosage, we are of opinion that excellent results may be obtained, especially in the treatment of localised tuberculous lesions, without the use of the "Immunity Thermometer"; success in the vast majority of cases attending the employment of minute doses at long intervals. Generally speaking, the feelings of the patient are a safe guide." This opinion of experienced workers, borne out as it is by many others, is of the utmost importance. The main objection to the wide adoption of the vaccine treatment up to the present has been the trouble and expense of maintaining the opsonic control which was supposed to be necessary; if this control can be done without, then the greatest obstacle to vaccine treatment vanishes. R.

Bacteriology of Summer Diarrhœa of Infants.—Morgan publishes (*British Medical Journal*, July 6th, 1907) the results of a bacterioscopic examination of a large number of cases of summer diarrhœa of infants. Cultures were made from the fæces, intestines, mesenteric glands, or spleen in each case. In a small proportion of cases the B. Gaertner was found, and in a few others organisms resembling but not identical with the B. Flexner and B. Shiga. The preponderating organism was one which Morgan believes has not been previously described. It was isolated from 28 out of 58 cases of diarrhœa in 1905, and from 15 out of 34 in 1906. In its general characters it closely resembles the bacillus of hog cholera of MacFadyean, but differs from it in its action on litmus milk, in the production of a larger amount of indol, and in its failure to produce acid and gas in maltose and dextrin. It is pathogenic for animals, producing diarrhœa and death in young rabbits, rats, and monkeys when these animals are fed on cultures. The condition produced in monkeys closely resembled infective diarrhœa in children. Morgan concludes that the type of summer diarrhœa observed in this country differs clinically and bacteriologically from the type seen in America. R.

Anti-rabic Treatment at the Pasteur Institute.—Viala publishes (*Annales de l'Institut Pasteur*, June 25th, 1907) a statistical abstract of the cases treated for rabies in 1906 at the Pasteur Institute. During the year 773 persons submitted themselves to the vaccine treatment; two died of hydrophobia. In one of the fatal cases, however, the disease showed itself less than fifteen days after the end of the treatment. Omitting this case, the mortality would be 0.13 per cent. This is the lowest mortality rate in the history of the Institute, the nearest to it being 0.18 in 1902. The number of persons treated is slightly greater than in any year since 1902. The great diminution from the years earlier than that is due to the establishment of several other anti-rabic institutes in the provinces of France. At present, there are no less than five, situated respectively at Marseilles, Lille, Montpellier, Lyons, and Bordeaux. Of the persons treated at the Pasteur Institute last year, 22 came from Holland, 1 from England, 1 from Russia, and 1 from Greece, the rest being French. In the two cases which ended fatally, the patient was bitten in the face. R.

Pathology of Beri-beri.—Hewlett and De Korté publish (*British Medical Journal*, July 27th, 1907) some observations on men and monkeys which justify a suggestion as to the causation of beri-beri. They obtained several monkeys suffering from a disease closely resembling beri-beri; the animals were very ill, most of them having œdema of the face and genitals; the urine never contained albumin, and the knee-jerks were either increased, diminished or absent. They all died, and the only constant lesion found was congestion of the kidney, accompanied by cloudy swelling, and in scattered areas hæmorrhages into the convoluted tubes. Hyaline casts were constantly found in the urine, which also in some cases contained highly refractile cells of an unknown nature (? protozoa). Attempts to infect healthy monkeys from the sick were not very successful, but in two animals the eyelids became puffy, and the knee-jerks exaggerated. The authors next fed monkeys on urine from human beri-beri patients, a somewhat similar form of illness being produced. The urine of patients suffering from beri-beri was carefully examined. Granular and hyaline casts were present in abundance. In addition, three peculiar forms of body were seen: (1) Small spherical refractile, bodies 2 to 3 m. in diameter, apparently possessing a thick capsule and hyaline contents. They did not give the reactions for fat; (2) large, globular cells, 20 m. in diameter, containing a cytoplasm studded with very refractile granules, and with a single nucleus; (3) large cells, 30 m. in diameter, enclosed in thick capsules, with a finely granular oval nucleus with rounded nucleoseus. These bodies the authors regard as possibly protogoa. Finally, the kidneys of subjects dead of beri-beri were examined; the lesions found were similar to those present in the monkeys' kidneys described, but more intense in degree. As a working hypothesis, the authors suggest that beri-beri is a protogoan infection, that the infective agent is eliminated in the urine, and that the urine is the source of infection. R.

Preparation of Homologous Tubercle Vaccine.—Allen describes (*Journal of the American Medical Association*, July 20th, 1907) a method of preparing personal or homologous vaccine from tubercular sputum. (1) Fresh sputum was carefully washed in six changes of normal salt solution. (2) The sputum was thoroughly beaten up with an ordinary egg-whisk for ten to fifteen minutes. (3) The foam was collected and liquefied by placing it under an exhaust pump. This was found to be the best means of obtaining bacteria free from pus cells (4) The resulting emulsion was concentrated by centrifuging. (5) The fluid was standardised by a modification of Wright's method for other bacteria. The modification consisted in counting the red blood corpuscles in a given number of marked squares before staining, then staining, and counting the tubercle bacilli in the same squares. (6) The preparation was sterilised by heating on two successive days for two hours at 60 deg. C., and an antiseptic added. (7) That the fluid might possess the various toxins and ferments which would be destroyed by heat, a portion of the emulsion before sterilisation was passed through a Beakefeld filter. This filtrate, which was difficult to standardise, was added to the vaccine before injection, or injected separately at the same time. The obvious objection to this elaborate method is that equally good results could be got by making cultures from the sputum, and making emulsions therefrom in the ordinary way. Allen argues, but is hardly convincing, that bacteria grown in culture should differ in their biological effects from bacteria direct from the lung. The author recalls the interesting historical fact that "in 1638, an English professor, Dr. Robert Fludd, advised sputum injections as a cure for phthisis." R.

Histogenesis of Cancer.—Oertel (*New York Medical Journal*, July 6, 1907) describes the changes in a case of cancer of the liver in which he believes he was able to trace the metamorphosis of liver cells into cancer cells. He noticed these stages: (1) The liver cell has lost much of its protoplasm by granular degeneration. The nucleus has lost most of its chromatin, and its nucleolus has disappeared. (2) Regeneration is beginning. The nucleus is enlarged, showing more chromatin granules, and a faint nucleolus. (3) The chromatin granules have coalesced, and the nucleolus is distinct. At the same time there is an accumulation of protoplasm around the nucleus. The metamorphosis is now complete, a cancer cell having been produced. These cells still maintain their lobular arrangement, but when they reproduce they break away from this, and the typical cancer growth is formed. R.

MEDICAL NEWS IN BRIEF.

The Metropolitan Hospital.

AT a meeting of the Metropolitan Hospital Fund, held on Thursday last at the Mansion House, it was reported that the executors of the late Mr. George Herring would pay to the treasurer of the fund £30,000 on account of the legacy bequeathed to the Hospital Sunday Fund, and it was decided that this should be included in the total amount of the fund which would thus amount to £74,165. The distribution committee recommended that disbursements of £68,134 3s. 4d., to 159 hospitals and institutions, 7 dispensaries and 27 nursing associations, and this was ordered. After considerable discussion, in the course of which it was stated that over 1,000 beds in the hospitals were at present unoccupied, and that 62 hospitals in London owed £150,000 to their tradesmen and bankers for current accounts, it was resolved, "That any hospital or institution at present receiving a grant from this fund be invited to consult the council of this fund before incurring further expense in providing additional accommodation for patients."

Tragic Death of a Medical Man.

WE regret to state that Dr. Rynne, of Cheltenham, was found dead on July 20th, at his house. He was about as usual on the previous day, and attended his patients. He rose at the usual hour in the morning, and, according to custom, went to the bath-room. As unusual delay occurred in his making his appearance, the bath-room was entered, and Dr. Rynne was found dead near the bath. He was about 38 years of age, and leaves a widow and three children.

At deceased's residence, on July 22nd, the Divisional Coroner conducted the official inquiry. The Coroner said that the facts were "very simple and very sad," and he was sure would elicit the sympathy of the jury with the widow and relatives of deceased. Mary Rynne, widow of deceased, stated that her husband enjoyed fairly good health. About five years ago he had something in the nature of a fit. On Friday last, he was about attending to his practice as usual. He retired to bed that night with witness about 12.30. Awaking in the morning, witness missed him from her side. On inquiries being made, he was found by witness's brother, Mr. O'Mara, inside the lavatory. The door was locked on the inside, and had to be forced open.—Stephen O'Mara, brother-in-law of deceased, said he arrived at Osborne Villas on a visit on Friday night. Deceased was then in good health and spirits. Witness corroborated the wife's testimony, adding that deceased was lying on the floor, attired in pyjamas and slippers. Witness raised him, and he seemed then to be dead. John Francis Johns, M.D., practising in Cheltenham, who knew deceased personally, gave the result of a post-mortem examination made by him, which showed that deceased had suffered from fatty degeneration of the heart. Death was due to syncope.—The jury returned a verdict accordingly.

The Royal Army Medical College.

THE Royal Army Medical Corps Staff have taken possession of the fine new Medical College, with façades to the river, next to the Tate Art Gallery, and Museum in Atterbury Street, erected by the Government at a cost of £80,000. The lower course of the college is built of grey granite, and the upper stories of brick, with stone dressing. The Grosvenor Road frontage is very imposing, the roof being supported by Ionic columns, resting on a granite portico base, over which is the Royal monogram. There are two blocks, one residential, to accommodate about eighty students, and the other contains the laboratory and museum. The college is equipped on the latest scientific model, and contains lecture and class-rooms, reading room, billiard-room, and officers' mess and quarters. The building comprises lower and upper ground floors, together with first, second and third floors.

It is expected that the college will become a centre for the study of scientific research and tropical medicine. Students who join the college will be young officers who are already qualified, but they will have to pass an entrance examination. There are two courses, senior and junior, which last respectively six and two months. The senior course will be taken by captains who have returned from their first foreign service, and they will undergo at the cost of the Government a special course of Army training by the professors of the college and certain physicians and surgeons of the London hospitals. Lieut.-Colonel H. E. R. James of the Royal Army Medical Corps, is commandant and director of studies, The professors, all of the Royal Army Medical Corps, are :—Military surgery, Major C. G. Spencer, M.B. ; tropical medicine, Lieutenant Colonel R. J. S. Simpson, M.B. ; hygiene, Lieutenant-Colonel A. M. Davies, A.M. ; assistant professor, Major C. E. P Fowler ; pathology, Lieutenant-Colonel W. B. Leishman, M.B. ; assistant professors, Major W. S. Harrison M.B. and Colonel F. J. Lambkin. The clinical teachers in medicine are Mr. H. M. Murray, M.D., and Mr. B. P. Hawkins, M.D. ; in surgery, Mr. G. H. Makins, C.B., and Mr. H. F. Waterhouse, M.B., together with seven other teachers in special branches. The college will be ready for the formal opening in the autumn, and it is hoped that the King may be pleased to perform the ceremony.

The Midwives Act, 1902.

The Local Government Board has issued to Boards of Guardians a circular directing attention to Section E of the new rules of the Central Midwives' Board recently approved by the Privy Council, the section in question relating to "regulating, supervising, and restricting within due limits the practice of midwives."

PASS LISTS.

University of Aberdeen.

At the graduation ceremonial held July 25th, the folowing degrees were conferred on candidates who had previously passed the examination :—

Degree of Doctor of Medicine (*M.D.*).—William Campbell Anderson, B.Sc., M.B., Ch.B.; Robert Brown, M.B., Ch.B. ; James Clark, M.B., Ch.B. ; Frederick William Ellis, M.B., Ch.B. Maurice Buchan Johnson, M.B., Ch.B. ; Peter Macdonald, M.A., M.B., C.M. ; William Mitchell Smith, M.B., C.M.

Degree of Master of Surgery (*Ch.M.*).—Alexander Mitchell, M.A., M.B., Ch.B.

Degrees (*M.B*) *and* (*Ch.B.*) *New Ordinances* (*with Second Class Honours*).—*Walter J. Dilling, *David Horn, B.A., George H. C. Lumsden, *James M. M'Queen, M.A., B.Sc ; Andrew M'Kay Niven.

Ordinary Degree.—Ernest W. Allaway, John W. Archibald, Thomas P. Clapperton, John Ferries, William I. Gordon, M.A., Alexander Horn, John Elrick Kesson, Benjamin Knowles, James Leask, Margaret C. Macdonald, Dalziel B. M'Grigor, William I. Mackintosh, James M. Mathieson, James A. Milne, Benjamin Mitchell, James Mitchell, John K. O'Neil Murray, Algernon Edgar C. Myers, Patrick Nicol, Arthur Shepherd, *Alexander Stewart, William T. Stewart, John M'Intosh Wilson, M.A.

* Passed Final Examination with Distinction.

The John Murray Medal and Scholarship to the most distinguished Graduate (M.B.) of 1907 was awarded to David Horn, B.A., Queensland.

The Diploma in Public Health was granted to Arthur G. Troup, M.B., Ch.B. (Aberd.).

The Conjoint Board of the Royal Colleges of Physicians and Surgeons of Edinburgh and Faculty of Physicians and Surgeons of Glasgow.

The following candidates passed their respective examinations in July, viz. :—

First Examination (*five years' course*).—Francis William Grant (with distinction); James Grant Morrin ; Morris William Rees (with distinction); Francis Patrick Quirk ; James Douglas Wright ; William Millerick ; John Boyd Michie.

Second Examination (*five years' course*).—Surcudra Kumar Sen (with distinction), Edith Huftton, Robert John Helsby (with distinction), Harold Hope Scott.

Four years' course.—Thomas Mitchell Jamieson.

Third Examination (*five years' course*).—Richard B. M. Sullivan, Osmonde Rusleigh Belcher, Thomas Sholto Douglas, Isaac Flack, Henry Frank Collins, Alexander Baxendale, Robert McConnell Blair.

Final Examination, and Admitted Licentiates of the Co-operating Bodies.—John David Jones, James Finbair Jefferies, John Robert Dunn Holtby (with honours), Hugh Clement de Souza, Walter Riddell, Isaac Flack, George Ernest Nash, Walter Ernest Barrett, Gilbert Elliot Aitken, Robert Kay Nisbet, David Williamson Morison, Cuverji Ruttonji Vevai, Jitendra Nath Rai, Clare Annis Langmaid, Bhairàwnath Donanath Khote, Edwin George Hodgson, Charles Jacobs Tillekeratne.

Army Medical Service.

The following is a list of successful candidates for Commissions in the Royal Army Medical Corps at the recent examination in London for which 59 candidates entered. The names are arranged in the order of merit :—

T. McC. Phillips, B.A., M.B., B.Ch., R.Univ.Irel. ; H. S. Dickson, B.A.Cantab., M.R.C.S.Eng., L.R.C.P. Lond. ; G. F. Dawson, M.A., M.B., B.Ch., Univ. Aberdeen ; H. V. B. Byatt, M.R.C.S.Eng., L.R.C.P. Lond. ; R. E. Todd, M.B., B.S.Lond., M.R.C.S.Eng., L.R.C.P.Lond. ; T. F. Lumb, M.R.C.S.Eng., L.R.C.P. Lond. ; H. Gibson, M.R.C.S.Eng., L.R.C.P.Lond. ; C. P. O'Brien Butler, L.R.C.P.& S.Irel. ; G. Petit, L.R.C.P.& S.Irel. ; J. B. Hanafin, L.R.C.P.& S. Irel. ; J. A. Renshaw, M.R.C.S.Eng., L.R.C.P.Lond. ; R. F. O'T. Dickinson, L.R.C.P.& S.Irel. ; W. R. O'Farrell, L.R.C.P.& S.Irel. ; R. De V. King, M.R.C.S.Eng., L.R.C.P.Lond. ; D. B. McGrigor, M.B., B.Ch., Univ. Aberdeen ; C. T. Conyngham, B.A., M.B., B.Ch., B.A.O., Univ. Dub. ; H. McC. Hanschell, M.R.C.S. Eng., L.R.C.P.Lond. ; J. R. Lloyd, M.R.C.S.Eng., L.R.C.P.Lond. ; H. W. Carson, M.B., B.Ch., B.A.O., R.Univ.Irel. ; R. G. S. Gregg, B.A., M.B., B.Ch., B.A.O., Univ.Dub. ; H. T. Treves, M.R.C.S.Eng., L.R.C.P.Lond. ; F. T. Dowling, M.B., B.Ch., B.A.O., B.A., R.Univ.Irel. ; J. C. L. Hingston, M.R.C.S.Eng., L.R.C.P.Lond. ; F. J. Stuart, K.B., B.Ch., Univ. Aberdeen ; B. A. Odlum, L.R.C.P.& S.Irel. ; W. R. Spong, B.A., M.B., B.Ch., B.A.O., Univ.Dublin ; J. F. Grant, M.B.,. B.Ch., Univ. Aberdeen ; P. H. Hart, B.A., M.B., B.Ch., B.A.O., Univ.Dub. ; A. E. B. Jones, M.D., M.B., B.Ch., Univ.Dublin ; A. Hendry, M.B., B.Ch., Univ. Aberdeen.

Indian Medical Service.

The competitive examination for commissions in the Indian Medical Service was held on July 23rd, 24th, 25th, 26th, and 27th. The subjects of examination were medicine and therapeutics, surgery and eye diseases, applied anatomy and physiology, pathology and bacteriology, midwifery and diseases of women and children, materia medica, pharmacology and toxicology. Thirty-three candidates presented themselves for 14 vacancies. The following is a list of the successful candidates arranged in the order of merit :—Hugh William Acton, L.R.C.P., M.R.C.S. ; Vivian Bartley Green-Armytage, L.R.C.P., M.R.C.S. ; Arthur Norman Dickson, M.B., Cantab., L.R.C.P., M.R.C.S. ; Arthur Norman Dickson, M.B.Cantab., M.R.C.S. ; Arthur Batoum Zorab, M.B., B.S.Lond., L.R.C.P., M.R.C.S. ; Alexander Glover Coullie, M.B., Ch.B., F.R.C.S.Ed. ; Robert Ernest Wright, M.B., B.Ch., B.A.O.Dub. ; William Hunter Riddell, M.B., Ch.B.Ed. ; Alexander James Hutchison Russell, M.A., M.B., B.Ch., St. Andrews ; Dewan Hakumat Rai, M.A., M.B., Ch.B.Ed. ; Francis Shingleton-Smith, B.A., B.C.Cantab. ; L.R.C.P., M.R.C.S. ; Arnold Thomas Densham, B.C.Cantab., L.R.C.P., M.R.C.S. ; Arthur Waltham Howlett, M.B., Ch.B. Vict. ; Frederic Allan Barker, B.A., B.C.Cantab. ; Arnold Newall Thomas, L.R.C.P., M.R.C.S.

Plague has made its appearance at Liverpool. At a meeting of the City Council on July 31st, Dr. Utting, chairman of the Port Sanitary Committee, stated that this week they had one case of plague in hospital, and twenty-four cases of suspected contact. Most of the suspected cases are those of foreign sailors shipped at Indian ports

The late Miss Emily Rebecca Leon has left legacies to the amount of £2,000 to the various medical and homœopathic institutions.

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies. Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessary for publication but as evidence of identity.

URBAN DISTRICT COUNCILLOR.—Inquiries tend to show that our correspondent's statements are not confirmed.

C. O. C. P.—It does not belong to the province of a medical journal to discuss a personal matter of the nature mentioned by our correspondent.

HOUSE PHYSICIAN.—Apply to the Agent-General of Colony named, who will doubtless give every detail required. We have not heard of a vacancy for the post having been declared.

SPES.—Wherever possible a patient requiring the high frequency treatment should always be sent to a medical man who has special knowledge of the subject.

M.R.C.S., L.R.C.P. (Leeds).—Our correspondent is advised to write for a catalogue of the latest works and to ask for a list of those upon the subject named which are being most recommended.

DENS.—Yes, it is a recognised fact that the teeth of girls decay sooner than those of boys. The cause seems to be related to the fact that girls are more precocious than boys, and that, as they attain full development sooner, they begin correspondingly sooner to show signs of retrogression.

DOCTOR OR CABDRIVER.

A medical man in a certain small town was rung up about one o'clock in the morning and asked what he would charge to accompany the caller to a country house some three miles away. "Is it a serious case?" inquired the sleepy doctor. "Very serious." "All right; I'll come. I shall have to charge you a guinea." The doctor got dressed, and, having harnessed his horse, they set off. Arrived at their destination, his companion handed over a guinea, and jumped out of the trap, thanking the doctor very profusely for his service. "But—the patient?" "I'm the patient," cut in the other. "You see, doctor, I arrived by the last train, and the people at the inn would not drive me here under 30s. I thought it too much, so I called on you. You offered to do it for a guinea—so here we are."

DISTOMA.—The method originated, we believe, at the Huddersfield Infirmary, and decalcified or cancellous bone certainly seems very useful in some cases of chronic ulcer. You would probably have to prepare it yourself, or make special arrangements with a firm.

LEX.—We have not made up our minds whether the case calls for comment. Such, of course, could only be adverse, and the facts we have are too meagre to justify us in entering the fray. Could you give us ampler details from the spot? If so, we may be able to take the question up in earnest.

DELEGATE.—We fear you will be much too late, but you might write direct to one of the General Secretaries.

GLASWEGIAN.—We cannot enter into private correspondence in the matter. There is no reason why your letter should not be published, and we should be happy to do so if you wish. We can hardly be expected to advise under the circumstances, though we shall be happy, as we say, to publish your complaint.

W. H. S.—Your letter on "The Collection of Debts owing to Medical Men" is unavoidably held over to our next.

OUR PARIS CORRESPONDENT'S weekly letter was undelivered in time for press, owing to the Bank Holiday. It will appear next week.

Appointments.

DE SOUZA, D. H., M.B., B.S., B.Sc.Lond., Demonstrator in Physiology at the University of Sheffield.

SWANN, W. F. G., B.Sc.Lond., Assistant Lecturer and Demonstrator in Physics at the University of Sheffield.

BOWMAN, G. F., M.B., M.Ch.Vict., Medical Officer of Health by the Limehurst Rural District Council.

GOULD, H. U., M.B., B.S.Cantab., Certifying Surgeon under the Factory and Workshop Act for the Shaftesbury District of the county of Dorset.

HAWKSLEY, W. L., M.B., Ch.B., D.P.H.Liverp., Assistant Medical Officer at the New City Hospital for Infectious Diseases, Fazakerley, Liverpool.

HOLLICK, B. S., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Act for the Sturminster Newton District of the county of Dorset.

LEWIS, WILLIAM JAMES, L.R.C.P. and S., L.M.Edin., L.F.P.S.Glasg., Medical Officer of Health by the Pontardawe (Glamorganshire) Rural District Council.

Vacancies.

Royal Victoria Hospital, Bournemouth.—House Surgeon. Salary, £100 per annum, with board, lodging, and laundry. Applications to the Secretary on or before August 14th.

Grimsby and District Hospital.—Resident House Surgeon. Salary, £100 per annum, with board, lodging, and washing. Applications to S. M. Forrester, Secretary, Victoria Chambers, Grimsby.

North Lonsdale Hospital, Barrow-in-Furness.—House Surgeon. Salary, £100 per annum, with board and lodging. Applications to the Secretary, North Lonsdale Hospital, Barrow-in-Furness.

Bailbrook House, Bath.—Medical Superintendent. Salary, £450 per annum, with board for self and wife if married, furnished quarters, laundry, attendance. Applications to Herbert Coates, Secretary, 49 Broad Street, Bristol.

Bridgnorth and South Shropshire Infirmary.—House Surgeon. Salary, £100 per annum, with board and lodgings in the Infirmary. Applications to the Hon. Secretary, the Infirmary, Bridgnorth.

Royal South Hants and Southampton Hospital.—House Physician. Salary, £100 per annum, with rooms, board, and washing. Applications to T. A. Fisher Hall, Secretary.

Brighton, Hove, and Preston Dispensary.—House Surgeon. Salary £160 per annum, with furnished rooms, coals, gas, and attendance. Applications to C. Somers Clarke, Hon. Secretary, 113 Queen's Road, Brighton.

Manchester, Corporation of.—Monsall Fever Hospital.—Fourth Medical Assistant. Salary, £100 per annum, with board, lodgings, and washing. Applications to the Chairman of the Sanitary Committee, Public Health Office, Town Hall, Manchester.

Burgh of Paisley.—Infectious Diseases Hospital.—Assistant Medical Officer. Salary, £100 per annum, with board, washing, and attendance. Applications to Fra Martin, Town Clerk, Municipal Buildings, Paisley.

Egyptian Government.—Kasr El Ainy Hospital.—Resident Medical Officer. Salary, £250 a year, with quarters, servants, washing, coal, and light. Applications to The Director-General, Public Health Department, Cairo.

Egyptian Government.—Ministry of Education.—School of Medicine, Cairo.—Assistant to the Professor of Pathology. Salary, £E.320 per annum. Applications to The Director, Government School of Medicine, Cairo, Egypt.

Northampton, County Borough of.—Medical Officer of Health. Salary, £400 per annum. Applications to Herbert Hankinson, Town Clerk, Guildhall, Northampton.

County Asylum, Mickleover, Derby.—Junior Assistant Medical Officer. Salary, £120 per annum, with furnished apartments, board, washing, and attendance. Applications to Dr. Legge.

Newport and Monmouthshire Hospital—Secretary and Superintendent. Salary, £200 per annum. Applications to the Chairman, Newport and Mon. Hospital, Newport, Mon.

Clifden Union.—Medical Officer. Salary £160, with £10 a year as D.P.H., and Registration and Vaccination Fees. Applications to P. H. Bodkin, acting Clerk of Union. (See Advert.)

Births.

MCNABB.—On July 31st, at Withern, Alford, Lincs., the wife of A. A. J. McNabb, M.B., of a son.

HEY.—On August 1st, at 1 Princess Terrace, Ripon, the wife of Samuel Hey, M.R.C.S., of a daughter.

UNDERHILL.—On August 1st, at Castle View, Newport (I.of W.), the wife of S. O. H. Underhill, M.R.C.S., L.R.C.P., of a son.

Marriages.

HEBB—WOLFGANG.—On August 1st, at St. Mary's Church, Byfleet, John Harry Hebb, B.A., M.B., B.Ch.Oxon., only son of the Rev. H. A. Hebb, M.A., headmaster of the Royal Masonic School, Bushey, Herts, to Ethel Kathleen, youngest daughter of the late Elias Wolfgang, of Liverpool.

HUGHES—RIDDELL.—On July 31st, at St. John's, Meads, Eastbourne, Stanley, younger son of the late John Hughes, Esq., of Tero-Law, to May, elder daughter of the late James Riddell, Esq., of Beckenham, and Badulipar, Assam.

POWELL—SENNETT.—On July 31st, at St. Patrick's Church, Hove, Sussex, Edgar Elkins Powell, Major, R.A.M.C., to Gladys Violet, elder daughter of Lieut.-Colonel and Mrs. C. T. Sennett.

Death.

AUBIN.—On July 27th, at La Motte Street, St. Heliers, Jersey, Thomas John Aubin, M.D., M.R.C.S., in his 70th year.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXV. WEDNESDAY, AUG. 14, 1907. No. 7

NOTES AND COMMENTS.

August Congresses.

IN August, it has been said, the middle-aged man's fancy lightly turns to thoughts of congresses, and this year the first half of the month has produced, if not a surfeit, at least a plenitude for the most hardy medical digestion. The British Association and the British Medical Association meetings are annual events, but the holding this year of the International School Hygiene, the Housing, and the Esperanto Congresses in England forms a pleasing method of bringing those important subjects to public notice. Although there is nothing peculiarly medical about Esperanto, there is no doubt that the want of a *lingua franca* for medical men has been badly felt since an intimate knowledge of Latin ceased to be part of the education of members of the learned professions. In the fifteenth, sixteenth, and seventeenth century, before the English had developed a good flexible prose, it was almost possible to write with scientific accuracy in the language, but when the common tongue became capable of expressing definite and exact shades of meaning, writers naturally preferred to use it rather than an alien one. The result, however, was that the British scientists became more and more isolated from their continental brethren, till now, in spite of summaries and extracts of foreign papers in the medical press, the average opinion of continental medical men on subjects of current interest is comparatively little known in this country. Moreover, before conducting any scientific research, it is necessary that a man should be a good linguist, if he is to be furnished with knowledge of all that has been done abroad in the particular line he proposes to pursue, and wishes not to work over ground that has been well trodden already.

Esperanto and the Natural Sciences.

RECOGNISING the enhanced value of a record which appeals to all nations, the Pathological Society recently started appending a brief Latin description of their specimens to the ordinary one in the vernacular, and no doubt research-workers and record-hunters abroad will be much indebted to them for the trouble. Still it stands to reason that however adaptable classical Latin may be for scientific records, and even in this it is greatly inferior to Greek, it is not possible to revivify the language for ordinary purposes of communication, written and spoken, as the educational curriculum and brain of man would not bear it. On the other hand we shall be curious to see whether Esperanto which seems to answer well enough for the jargon of the mart, is sufficiently accurate and flexible for scientific records. We should think it highly probable that it is not, in spite of the illimitable facilities it possesses for coining words, because of the paucity—or rather complete absence—of inflexions it apportions to its nouns and verbs. Certainly Esperanto has caught on as neither Volapuk nor any of the dozen other artificial languages has yet, and if it is capable of bearing all the strain that medicine and the allied sciences can put upon it, the boon to research-workers, and indeed to ordinary practitioners, will be immense.

The British Association and Alcohol.

AN immense amount of interest was taken by the public in the debate on the value of alcohol in the Physiological Section of the British Association Meeting. Considering the importance of the subject from the sociological point of view, and also the amount of attention that has been drawn to the subject in one way and another during the last few months, there is not only no need for surprise that so much interest was exhibited, but considerable cause for thankfulness. It cannot, however, be said that the debate advanced the question very far, nor is it likely to make converts to either side, but at any rate it sets forth, to a certain extent, the general opinion of the profession that alcohol is not nearly so useful a drug as was thought thirty or forty years ago. That perhaps is not much, but it must be remembered that even in the Olympian atmosphere of the British Association it is difficult, if not impossible, for speakers to rid themselves entirely of prepossessions, so that, whereas the temperance advocate is likely to minimise a piece of evidence that tells against him, the moderate drinker will insensibly be biassed the other way. The weight of the speakers on the whole was certainly in favour of alcohol in small quantities not being deleterious; but then it might be asserted that those speakers were themselves wine-drinkers.

Professor Cushing's Views.

PROFESSOR CUSHING, who opened the debate in a long and able speech, probably put the case as fairly and temperately as can be. Taking the question of alcohol as a digestive he showed that although there was slightly more active movement of the digestive organs when pure alcohol was administered in small quantities, and a larger secretion of gastric juice, yet this secretion was poor in ferments, and therefore of less avail for purposes of digestion. On the other hand appetite is a great factor in the regulation of digestion, and therefore in those people who are accustomed to a wine and like drinking it, there may be some increase in digestive power by taking a little. Professor Cushing argued, moreover, that it is an undeniable fact that 95 per cent. of alcohol taken undergoes combustion in the tissues, and is consequently a source of energy. Its action he compared to sugar, showing that the energy produced by its combustion may be used for heat formation and mechanical work, and that it may lead to the deposition of fat and consequent economy of the nitrogen store. Further he said that while it is universally admitted that alcohol in large quantities diminishes the tissue-resistance to disease, it is not shown that small quantities had this effect, for although animals treated with alcohol are more susceptible to pathogenic inoculations after they have been subjected to alcohol than before, it is important to remember that alcohol has a very different effect on animals to that which it has on man, animals being merely narcotised, whilst men are excited. He further described some experiments with type-setters and with students which showed that their respective capacities for quick and accurate work were diminished by alcohol.

Man needs but little. A MORE admirable summing up of the present position of the alcohol question than that given at the end of Professor Cushing's paper it would be difficult to find. He said that alcohol may be of some value in therapeutics as a means of making food more attractive, and thus of improving digestion; that it possesses some good value in itself; that it acts as a cerebral depressant, and may be valuable in disease on account of this quality; that it may aid a failing heart; that small doses exercise no definite poisonous effects on the tissues, but that small repeated doses, though suspect, have not been shown to be deleterious. These conclusions were criticised in one way and another by the various speakers, but we venture to think that they stood it very well. As a working hypothesis they would be difficult to beat, and as such they may remain till fuller knowledge is gained on this vexed question. We stand in about as little danger now of heroic doses of alcohol as of heroic blood-lettings, and probably for the same reason, that they were both overdone.

The King and the School Hygiene Congress. OF the School Hygiene Congress the first thought that occurs is that the Committee were lucky in getting together a Congress at all. From the revelations of Sir Lauder Brunton in his inaugural address, it seems that a fortnight ago the whole thing seemed likely to fizzle out, and it was only through the personal influence of the King that the matter was eventually put through. The King, indeed, is the humanising influence in our Government machinery, which last creaks and rumbles ominously when subjected to any unusual strain. The difficulty which the Board of Education and the Foreign Office manufactured for themselves was not apparent to anybody but the disputants, and if it were not humorous it would be utterly degrading to think that the squabbles of two public offices had to be reconciled by the personal intervention of His Majesty before a useful scientific Congress could be held and the guests invited. Scientific men at least will feel grateful to the King for not allowing a slur to rest on their hospitality, and we trust that the lesson that the incident involves will be taken to heart by the young gentlemen in Whitehall who like to direct the affairs of the nation according to their own ideas of what should and should not be done.

LEADING ARTICLES.

The Cult of the Child.

ONE of the more important signs of the times is the increasing care we are paying to our offspring. Fortunately our awakened interest is not fated to assume the attitude of simple curiosity that is sterile of results, for the whole range of achievement of modern medical hygiene is at hand, to say nothing of its complicated and extensive machinery. Nor can it be said that we are dealing with matters that have not come within the purview of modern science, for the study of the environment and conditions of childhood has become an exact and comprehensive speciality. No better proof of the latter statement could be wished for than the International Congress of School Hygiene which has recently concluded the labours of a great meeting in London. The number and variety of the communications and discussions advanced by the members of that body emphasises in no small degree the far-reaching relations of the particular condition of environment dealt with under the title of school hygiene. One of the most interesting considerations, however, is the fact that the subject is engaging the earnest attention of all civilised nations; in short, wherever the need of State education of the child has been recognised, there the necessity of the scientific care of his school environment is becoming accepted as an inevitable corollary. The position thus entailed is so strictly logical that it is somewhat of a wonder that it was not established long ago. But after all the science of public health is itself a comparatively recent creation and its application, notably in the case of tuberculosis, still halting and unsatisfactory. Yet who can doubt that the millenium of early sanitary pioneers like Parr and Simon will one day come upon the nation? In a certain sense the deliberations of the International School Congress may be regarded as the natural outcome of their labours. At any rate, it is certain that civilised society will in future take steps to safeguard the health of its school children. It is obviously of little use to bewail the physical degeneracy of our race if we neglect its nurture during the crucial years of infancy and childhood. There are, of course, many difficulties in the way of securing an effectual control of the health of scholars, both as regards parents and as regards local administrative bodies. There is no doubt that the legislature must sooner or later enforce proper standards of sanitary construction in all cases. More delicate ground is touched in the attempt to apply individually a system of detailed medical inspection, which is an absolutely essential condition of the hygienic control of school life. Without the consent of parents, and possibly also of scholars themselves, it would probably be illegal to conduct an ordinary physical examination, including such necessary steps as an enquiry into the state of the scalp and the throat. Difficulties of this kind, however, are of a somewhat theoretical nature, and are hardly likely to present any serious obstacle in actual practice. So far as the medical profession is concerned there are several aspects of the question that deserve careful attention, especially now that universal medical inspection of schools is certain to become an established fact in the near future. First of all there is the relation of the school medical inspector to the general practitioner, obviously a matter of importance. At first sight it would seem advisable, wherever possible, to insist that the inspector shall be a special officer not engaged in private practice, and therefore not likely to come into collision with outside general practitioners. Then there is the question of fees payable for outside medical men by education authorities. At present there is a reprehensible tendency for the State to demand the services of medical men without remuneration as in the case of birth and death certificates. The school authorities wisely determine a child suffering from ringworm shall not attend school. They demand a certificate which is, as a rule, obtained free from a hospital or from a general practitioner. In any case the school committee pays nothing for the information, and in other cases the general practitioner is expected to supply his professional information gratis. A matter of this kind should be most carefully safeguarded by medical members of Parliament, for as a rule the legislature year by year demands fresh services of medical men, but neglects to make provision for their adequate remuneration. In this problem of school hygiene the medical profession is the primary source of inspiration, and as a matter of common fairness its material interests should be placed on a basis of adequate pecuniary recognition.

CURRENT TOPICS.

The British Medical Association and The General Medical Council.

In commenting recently on the relations existing between the British Medical Association and the General Medical Council, we expressed the hope that the Association would soon come to a definite decision on the question of its position as prosecutor before the General Medical Council. In this we have not been disappointed, for by an almost unanimous vote, the Representative Meeting at Exeter last week expressed its approval of the action of the Ethical Committee in appearing as prosecutor in a recent case. That the members feel very strongly in the matter is evident, not merely from the vote, but still more from the fact that the vote was given in the face of the opinion of counsel that the application of the funds of the Association in this direction is illegal! If any member objects to the funds being spent in this way, it will be necessary for him to proceed in the High Courts for an injunction to restrain the Association—a risk which apparently the Representative Meeting was willing to run. Apart altogether from the question of the wisdom of the Association taking on these extra functions, there can be no doubt but that it is unwise to proceed by illegal means to arrive even at an admirable end.

Finger-Licking by Clerks.

In these latterday scientific times many of our cherished habits and customs have gone by the board. Beyond a doubt a host of others will follow before the man in the street may hope to approach the standard fixed by men of science. Of all the filthy and disgusting habits there can be none less capable of defence than that of licking the finger which is used for turning over leaves, for counting money and so on. The tram conductor offends in this way that he may get a quicker and a lighter grip of the ticket that he hands, laden with countless bacteria, to his luckless passenger. So too, among other public servants, the hurried railway clerk, to whom fractions of seconds are of value, does the same thing with tickets and with money, in which latter case the customer pockets myriads of microbes along with his change. Clearly if the finger-licker is suffering from tuberculosis, diphtheria or any of the hundred-and-one microbial maladies that may affect the mouth, he distributes to the public the germ of disease on the surface of tickets and of coins. Therefore he should not lick his finger. How is he to be prevented? Shall the man in the street read him lectures, or educate him at an early age in schools, or make it a punishable offence? Somehow he must be convinced of the horror of his ways, and persuaded that in future he must not lick his fingers.

Mr. Carnegie's Gift.

Mr. Carnegie, among his many princely benefactions, has never given anything, at any rate on a large scale, to the London hospitals, although it is well known that they all need extra support badly. The reason has always been supposed to be that Mr. Carnegie objected to the way they are managed; that he thought, in fact, they are not managed on sound business principles. His splendid gift of £100,000 to the King Edward VII. Fund last week came to Londoners as a pleasant surprise, but though Mr. Carnegie did not accompany the money with a stipulation, he sent with it a heart-felt wish that the committee would get to work on reform as soon as possible. While everybody admires.

the public spirit and self-sacrifice displayed by the many high-minded gentlemen who give up their time and energies to hospital work, it must be admitted that they have allowed conditions to master them, and that in the stress of competition for funds and patients they have been driven to use methods which in the course of private business they would condemn. Notwithstanding the fact that there are at the moment some one thousand beds unoccupied at London hospitals, and debts to the amount of £150,000 to bankers and tradesmen on current account, appeals for building funds still appear over and over again. As a matter of fact committees have found that the safest "draw" for subscriptions is to announce a building scheme or special appeal, and the temptation to resort to this measure of despair increases with its success. When the buildings are finished all the money is used up, and as likely as not either the beds are not occupied or the hospital has to sell stock to keep them open. We hope with Mr. Carnegie that more reasonable methods will take the place of these gambling expedients.

Performing Lions and their Performances.

JUDGED from the point of view of the circus contents bill, the British public must retain a fair share of primæval savagery. Otherwise, the enterprising showman, who reads his audience like an open book, would not take so much pains to provide them with a hundred and one entertainments in which human life hangs, as it were, on the hazard of a thread. Every now and then some acrobat breaks his neck, or some lion-tamer is torn to pieces before a shrieking mob of sightseers. Yet humane society which passes bills to prevent cruelty to animals, and holds the scientific vivisectionist up to public pillory, permits these wanton side shows, with their gruesome work, to go on in the interests of the showman's till. Only the other day at Gloucester an attendant was killed by a lioness belonging to a travelling lion-tamer, who declared that the beast had always been regarded as harmless and docile. That fact merely proves that it is impossible to say when the lion has been effectually "tamed." A terrible death of the kind mentioned furnishes a grim satire on the civilisation and humanity of to-day, which appeals to great Heaven anent atrocities in Macedonia or the Congo State, and allows fellow countrymen and countrywomen to be mauled to death before their eyes, not only without a protest but even paying for the privilege of witnessing the unholy and degrading performance, which attracts many by its proffered butchery.

Mr. John Burns and Gratuitous Medical Service.

WHEN Parliament passes a measure that necessitates legal work, the lawyers in the House take care that provision is made for proper payment for such service. When new medical services are demanded, however, it is only rarely that the question of remuneration is mentioned. As a rule, the politicians concerned adopt the attitude of the outside public, namely, that they shall get as much gratuitous work as possible out of the medical profession. A good instance of this kind is the Bill for the Notification of Births recently brought before the House as a private Bill, and since adopted by Mr. Burns on behalf of the Government. It provides that a medical man must notify a birth within 36 hours, but gives him no fee for furnishing the information and signing the necessary document. Were a corresponding duty to be thrust upon a solicitor he would secure six and eightpence for every step in connection with the formality. Of all men we should imagine Mr. John Burns would be the first to recognise that the labourer is worthy of his hire. Now that the injustice of the proposal to saddle an honourable but by no means rich profession with fresh unpaid responsibilities has been pointed out to the right honourable gentleman, he surely will take steps to remove an obvious flaw from an otherwise most desirable measure. If the income of the medical practitioner is not reinforced from State sources, directly or indirectly, there seems to be some danger of his being forced ultimately out of the field, so keen is the competition with hospitals and with numerous forms of unqualified practice.

Japan leads the way in School Inspection.

THE appearance of Japan upon the stage of the world's politics offers much food for reflection. Perhaps the most salient feature of that remarkable people is their firm grasp of the practical aspects of modern scientific principles. By seizing upon advanced methods of tactics, weapons, transport, and medical service, the Japanese have crushed the power of probably the most potentially powerful country on the globe. But it is not only in warfare that Japan leads the way. In the matter of education she is an easy first, so far as medical inspection is concerned, and, in point of fact, has left the United Kingdom lagging hopelessly in the rear of the international struggle. Japan has recognised the fundamental truth that the aim of all true education should be to produce that type of citizen who shall be the fittest in all respects, whether mentally, bodily, or morally. She has not entrusted so vital a matter to the selfish arbitration of party politics, but has gone straight down to the root of the thing, and straightway appointed something like 9,000 medical school inspectors. Here, in Great Britain we have less than a hundred such officers appointed by local authorities who have availed themselves of their power in that direction, and even then their chief care is for the buildings rather than for the scholars. The first serious attempt to apply the system of medical school inspection universally was made in Mr. Birrell's Education Bill thrown out last year. It is to be hoped, however, that before long the Statute Book will be extended by a provision of the kind, which will to some extent enable England to remove the defect which now so seriously handicaps her in the development and progress of her race.

Lead as an Abortifacient.

AN inquest last week in the neighbourhood of Sheffield has called attention to the lamentable practice of taking lead pills to procure abortion. The deceased was a married woman, who died in hospital as the result of blood poisoning following abortion. While under treatment she confessed to the surgeon that she had taken diachylon from a plaster mixed with bread crumbs. Careful inquiry failed to reveal where the lead was obtained, and the jury returned a verdict that death was probably caused by the taking of diachylon pills to procure abortion. The Coroner spoke in the strongest possible terms of this terrible evil which of late years had sprung up among women. In certain districts, of which Sheffield appears to be one, the practice has become notoriously common. In these days of social legislation it would be well for the Government to revise the Sale of Poisons Acts, especially with regard to the sale of diachylon. Another point that at the same time might be alluded to with advantage is the resolution to make it compulsory to keep all liquid poisons in distinctively shaped bottles. Only a few days ago a lady was poisoned by mistake with carbolic acid which a servant took from a bottle precisely resembling the regular physic bottle by her side.

Medical Referees and Women.

In the report of a recent meeting of the Bradford Trades Council, objection was taken by the Executive to the appointment of a particular medical referee for their district on the ground that he was medical officer to a railway company on whose behalf he would also have to act in cases of accident as employers' medical adviser. Mr. F. W. Jowett, M.P., said he had spoken to the Home Secretary personally about the matter, and in the course of his interview Mr. Gladstone told him that he was anxious to know if women workers were desirous of having medical referees of their own sex to examine them, and Mr. Jowett proposed taking steps to find out. We venture to express our opinion that this suggestion raises the sex question in medicine in a most unfortunate form, and one which we fancy the women members of the profession will resent as much as men. The only possible reason why women workers should be examined by special women referees is that there would be some unpleasantness or impropriety in their examination by men, a suggestion which we fancy the Home Secretary will see, on reflection, to be offensive to medical men. Women workers in factories are accustomed to statutory examination by the factory surgeon on many occasions, and they come to look on him in the light of a tutelary deity who guards them from any injustice on the part of inconsiderate employers, and that view is exactly what the profession likes them to take. Moreover, it is common knowledge that such women-workers in their confinements and in times of sickness seek the aid of masculine medicals, who become, in most cases, their honoured friends. Women doctors, for their part, are generally anxious, as we have always gathered, that they should be treated on their professional merits, and be looked upon, from the point of view of society, as medical practitioners, simply and solely, without reference to sex. It is, therefore, quite gratuitous that the latter question should be raised in regard to the appointment of medical referees, and we think Mr. Gladstone will be well advised if he makes his appointments in the present by professional suitability, as recommended by the Departmental Committee. It is much to be hoped that the Government and other official bodies will steadily discountenance the importation of the element into medical appointments in which it does not naturally exist.

PERSONAL.

A Banquet was recently held at Porth in honour of Dr. Ivor H. Davies, who has left the district to take up his residence at Llantrisant. The occasion was marked by the presentation of a handsome silver service and an address.

Lieut.-Col. A. W. Browne, late R.A.M.C., has been appointed to Militia medical charge at Armagh. Major S. Macdonald, M.B., C.M., from Woolwich, has been appointed to Army Medical Service at Hong Kong.

Mr. Andrew Carnegie has given unconditionally the sum of £100,000 to King Edward's Hospital Fund for London. Mr. Carnegie expresses the desire that it should be used as seems best, "the more strenuously for reform the better."

Sir John Dickson-Poynder opened the International Housing Congress at Caxton Hall, Westminster, on August 5th.

Dr. Hugh MacLean, of Aberdeen, has been awarded a Carnegie Fellowship for his research on "The Carbohydrate Material and Ferments of the Blood."

The executors of the late General Baynes has forwarded a second sum of £10,000 to the King's Hospital Fund for London.

Professor Howard Marsh has been offered, and it is understood, has accepted the Mastership of Downing College, Cambridge, which has been vacated by Dr. Alexander Hill.

The Foundation-stone of the new Out-Patient Department of the Cardiff Infirmary was laid by Sir William T. Lewis on July 30th. Mr. Edmund Owen subsequently addressed the visitors.

Dr. W. Wynn Westcott presided at the annual general meeting of the Medico-Legal Society at the end of last month. Mr. Justice Walker was elected president for the coming session.

We regret to record the death of Dr. W. D. Miller, of Michigan, till last year Professor of Odontology in the University of Berlin. Professor Miller was known throughout the world as an authority on the teeth, and he had been for a long time at the head of the Berlin University Dental Institute. He introduced the game of golf, in which he excelled, into Germany.

About one hundred of the American, Colonial and foreign delegates attending the second International Congress on School Hygiene paid a visit to Oxford on Saturday. Luncheon was partaken of in the hall of Christ Church, at the invitation of Dr. W. Osler, the Regius Professor of Medicine, who presided.

We regret to learn that, whilst cycling down a hill near Colwyn Bay, Dr. Greenhalgh, of Bury, lost control of his machine. He was thrown off, and sustained a broken arm, and an injury to his forehead,

A Clinical Lecture
ON
THE MORE RECENT TREATMENT OF THE INSANE (*a*)

By G. H. SAVAGE, M.D., F.R.C.P.,

Consulting Physician for, and Lecturer on, Mental Diseases, Guy's Hospital; Examiner in Mental Pathology, University of London.

Gentlemen,—I have named my address for this afternoon "The More Recent Treatment of the Insane," because I am always protesting against treating insanity as an entity, as a definite disease. We have to consider the insane person, and the treatment of the insane differs very materially now from that of even a very few years ago. A history of the treatment of the past is almost an essential to an understanding of the stage which we have reached now. By the way, the recovery-rate is not much greater now than it was 100 or 150 years ago. That, of course, one regrets, and hopes for better things. The Biblical treatment of the long past was not unreasonable; the treatment of Saul by David was certainly correct; and as to the treatment of Nebuchadnezzar—turning him out into the country till he recovered—that was a case of non-restraint treatment effecting a cure. We have only come back to that even now. The next idea was that all insanity was associated with theological error, that, in fact, every insane person was afflicted by some spirit, generally a spirit of evil; but, sometimes, a prophetic spirit. Therefore the only way was to eject the spirit. Consequently chains, chastenings, and whips were used. Sometimes he had to be cast out by stinks, therefore remedies like asafætida, which is still used in the treatment of neuroses, were used for the ejection of the devil. There is still, in the centre of Europe, a cathedral and a town, and around it some fifteen villages, called Gheel, "The City of the Simple," where for 700 years the people have been treated at the shrine of Dymphna. Here I spent a week of great interest years ago. I suppose I am asked once a week whether there is any objection to a patient being treated by "Christian Science," thus coming back to the old thing. Hypnotism I am constantly being asked about, and I shall refer to that later. As society came more closely together, people said they must be protected against the accidents resulting from the insanity of certain people and, to effect that protection, the insane were shut up. Asylums grew, and are growing still. In the earlier days they were not specialised; all cases of all kinds, whether curable or incurable, were lumped together. Now one of the great developments is the separation of them; so that there are not only idiot asylums, but idiots are being separated. Thus you find schools for feeble-minded and institutions and colonies for the weak-minded, who are not distinctly idiotic. And one of the developments which will have a very great influence in the future is hospitals for the insane. I have said to you before that there are two words which I should like to get rid of from the English language—"asylum" and "lunatic." It will take a hundred years, even after they have been abolished, to do away with the stigma; the old feeling that a person affected in his mind is therefore alien and must be shut off, so that a person suffering in his highest faculties is an outcast. And when one remembers that a very large proportion of these people get well, and a larger proportion than the public believes remain well for the rest of their lives, it is a shame that they should be treated as if they were altogether useless as soon as they have had one attack of mental disorder. In Glasgow—and we must admit that North of the Tweed they are in advance of us in many ways—they have now a Receiving Hospital, so that every person suffering from mental disorder who falls into the hands of the equivalent of the relieving officer or the police is sent to this hospital, not to an infirmary or an asylum straight away, unless he happens to be a typical general paralytic, or to have some incurable disease of that kind. There are two wards in this receiving hospital, and I spent a day there not long ago to see the types of cases, and to see the results. The result is that not more than half these cases go to an asylum at all, but are discharged. Drink is, of course, the cause in many of these cases, but not by any means the majority. I said to the superintendent that I supposed the acute alcoholics came back fairly frequently, but he said "No"—that their experience was that, short of a year, or even more, the treatment of an alcoholic for a month or six weeks in the hospital was as useful, in the long run, as asylum detention for two or three months. In fact, he said that unless an inebriate was going to be secluded for a year or two, the result of hospital treatment in bed, with strict supervision and dieting, and medicine to a certain extent, was as useful as prolonged treatment, and much more useful than simple detention for three or four months.

Another development is hospital asylums, of which type Bethlem is the oldest example. St. Luke's is another old institution. Scattered over the country there are establishments like the Holloway Sanatorium. What salvation is in that word "sanatorium"! People do not mind going to Holloway Sanatorium, but if it were called the Holloway Asylum they would shy at it. In York there is a Retreat, and similar institutions at Exeter, Gloucester, and Manchester; and they are to a great extent self-supporting; some pay for their care, some pay but very little; but those who pay more help to support those who pay very little. At Bethlem Hospital, the majority of patients pay nothing at all; a certain number pay two guineas a week; in some places patients are received for even a guinea a week. There is another development, which I feel particularly interested in, because when I was at Bethlem I revived it, that of voluntary boarders. At that time there was still permission for the Royal

---

Delivered at the Polyclinic, Chenies Street, London, February 27th, 1907.

hospitals, such as Bethlem, to receive a certain number of patients suffering from mental disorder, as voluntary boarders. I had difficulties, and I had a struggle. The authorities said: "Well, but this man is of unsound mind; he has got delusions." "Yes." "Will you receive a voluntary boarder who has got delusions?" "Yes." "But he could be certified." "Yes, but that is exactly what I don't want. The man says, 'I am supposed to be of unsound mind. I do not think I am. I am quite willing to come into a hospital where I can be under observation, and where you will see that you are wrong and I am right.'" A person who has had an attack of mental disorder once, or twice, and has recovered, says, "Next time I get like this I shall prefer to return." I remember in the old days a patient driving to Bethlem Hospital and saying, "I want to be taken in; I feel I am going off my head; only if you take me in you will send word to my family where I am." At Bethlem Hospital there are probably 25 voluntary boarders; at Virginia Water there are a large number of voluntary patients, and one hopes it will be still further developed. You can understand that in county asylums it would be rather a dangerous thing to have voluntary boarders. The Commissioners quite properly require that those who wish to become voluntary boarders shall say in writing that they wish voluntarily to so place themselves; and there must be some statement by an outside medical man, preferably a general practitioner, that in his judgment the case is a fit and proper one. Over and over again this sort of thing occurs to me: A man comes and says, "I will kill myself." "Nonsense! You feel you will kill yourself?" "Yes, and I will." "Don't. It will be inconvenient for you, for your friends, and for me, now you have consulted me. I will telephone to see if they will receive you at either of these institutions." Yes, they can receive him, and he goes. I send with him a note that I consider him a fit and proper person to go as a voluntary patient, and he goes. The wave of despair passes; he is treated medically, and is discharged recovered. The more people recognise that hospitals for mental disorder can be used like homes or like hospitals of another type, the more will be removed the current dread of those institutions. It is a great thing to feel that they are going there for treatment, not for detention; the great trouble felt by the insane is that they are no longer free agents.

The next improvement, again along Scotch lines, is boarding-out. They have a patient here and a patient there at small houses, people who have been acutely insane but have recovered up to a certain point. And we must remember that many surgical and medical cases have only partially recovered when they leave the hospital, but they may have at once to perform their social duties. One who has had acute insanity may be left lamed in mind; he may no longer be able to fill the position he did; he is weak-minded, but he may be perfectly harmless; he is the class of man who is a hewer of wood and a drawer of water in asylums. A large amount of work is done in asylums by chronic patients. Some of them are specialists; there was one in Bethlem who would do nothing but polish brass knobs, though he still believed himself to be the Holy Ghost. Boarding such people out enables them to live happier, freer, and less costly lives; and no doubt the practice is extending in England. In 1890, it was decided that there should be no more private asylums' licenses granted; consequently, the hospitals have grown, and are receiving large numbers of patients of a class who used to be sent to private asylums or to the cheaper asylums. Hundreds of people all over the Kingdom are asking to have patients. Nurses leave asylums, marry, and say they have a nice little house and can take a patient. Three thousand doctors have applied to me for patients, therefore there are a large number of patients living scattered about, I presume, and I fear there is great danger of abuse. The abuse which called lunacy legislation into being was largely the fact that, literally, people were living upon lunatics under their care; people farmed them. I am always maintaining that we do not so much want certification of the insane as notification of them. Let there be a notification of insanity when it reaches a certain line, just as there is a notification of fever. If a person is insane, but not dangerous to society, let it be known and the patient kept under some kind of supervision. Otherwise, I feel sure there will be abuse. Certain so-called "colonies" I find very helpful; there are epileptic, feeble-minded, and inebriate colonies. I do not like to give names, but I will describe one. A doctor has a farm of 1,200 acres. On that he has ten or a dozen small villas, bungalows, cottages, and in each of these is a farm bailiff, a cured patient, a City missionary, a cured inebriate, a cured morphinomaniac, or someone else who has experienced mental trouble. In each of these houses are two or three borderland cases, who have fallen in some way, and are out of step with society, yet who are not dangerous or suicidal. These individuals are absorbed into this colony, and they are gradually educated back to self-respect; they are trusted. The doctor himself knows nothing about payment; that is arranged with the head of each house. The results are extraordinarily good. I had a letter from him this week, wishing I could go down and see the batch of discharges which he is sending to Canada, they having been there a couple of years and learnt many occupations, including, of course, agricultural ones. Of course, one has to recognise that there are failures, but who does not fail? Our successes are built up upon our failures. Therefore the future treatment of insane people, especially young growing cases, is to put them in healthy conditions. Insanity is not a disease depending on a micro-organism, though it may in some cases spring from diseased states; but it is a want of relationship of the individual to his surroundings, and if you modify his surroundings you may often get him back to usefulness.

Now as to treatment. It seems to me we are always inclined to sway backwards and forwards. First, every lunatic must be shut up, and now the feeling among certain physicians seems to be that every lunatic ought to be sent travelling; and I have sometimes said that part of the Atlantic must be paved by these people. It is a very dangerous thing to send a person of unsound mind travelling unless you know all about him. Some time ago, I was told a patient was to be sent for a voyage, and I said I was very glad I was not going with him. Next I heard that after being a short time at sea he attempted to drown himself. The consequence was that the rest of the voyage, which was to do him so much good had to be passed in the cabin under the strictest supervision

Doctors have the common failing of recommending that which suits themselves. If a person has an inflamed eye he does not at once go to a picture gallery. He is put into a dark room, and is kept quiet. Melancholia, in many cases, is mental pain; and do you suppose that when the mind is suffering painful impressions it is best to exercise it? It requires rest. One man finds rest at the seashore; another in pottering about a garden or on a farm. One man who had an attack of melancholia which lasted a year, showed me a road he had made entirely, including quarrying the stone. He said, "That was my cure for melancholia." Doctors sometimes say, "Don't you think it will be a good thing to make him buck up?" I think it would be disastrous; but there are some to whom it would be immensely useful. A man makes a fortune before he is middle-aged, and he is induced to retire from business. He has devoted twenty-five years to making money, and thinking of nothing but money, and the making of it. He retires; and he has not got a healthy vice at all. If you cannot get him back to some business, then if you send him for a year or two's travel he may gradually settle down into a different man. Travelling is useful in certain hypochondriacal cases. When insanity depends upon physical disease, treat that disease; do not treat the insanity, but treat the individual. Travelling has its advantages, but it also has grave dangers. I have seen many people made very much worse by travelling, and many cases have ended fatally as a result. Then comes the swing of the pendulum the other way. "You say hospital treatment for the insane is good; very well, give them all 'rest cures.'" If the patient is badly nourished, if his digestion is failing, if he be physically weak, Weir-Mitchell treatment may be of enormous advantage. But if the person be a self-indulgent adolescent, he or she must not be allowed to soak in self-indulgence; it would be the worst thing possible. Brooding leads to hatching, and brooding in bed leads to all sorts of delusions. I have seen a person put to bed slightly depressed, and get up confirmedly deluded. But in some cases it is beneficial, as in the following case which recently came before me. I was asked whether a certain lady would not be benefited by a "rest-cure" in a nursing home. First, one had to decide: Is that person really insane, dangerously, so that it is not justifiable to send her to a nursing home? No. She was hypochondriacal, quarrelsome, and inclined to upset the household generally, wherever she was. She was about 2½ st. below her normal weight. She was put into a nursing home, isolated from her friends. Nurse No. 1 does not get on with her; Nurse No. 2 did very well. There are the surroundings of peace; she is not seen much by a doctor, nurses look after her chiefly, and massage is increased. She puts on 2½ st., and even more, and begins to think she is going to become too fat. But she is inclined to say "I am so happy here that I will stop here." Now comes the time to break down adhesions, and therefore one tells her to go somewhere else. She is sent to the home of a cultured lady who has had experience of such cases, and slowly she gets perfectly well. If she had had her way she would have gone on having "rest cures" for the remainder of her life. I have known a patient drift into that condition and not leave her room for twenty years; she liked the habit of living in retreat. One use of the Nursing Home is: You are called suddenly to see a woman who has become insane. Pending a decision as to the future, it is extremely convenient to be able to say: "Yes, the doctor thinks that a rest would be good for you, therefore you must go to bed, and you must have a nurse." That,of course, is watching to see which way the current is going to run.

Next, as to treatment by drugs. Nowadays people are apt to disparage drugs and drug treatment, but there is no doubt they are useful in some cases of mental disorder. They may prevent, or may shorten, a breakdown, or they may alleviate it in some way. I remember the day when patients were kept quiet by antimony and purges. That is no better than mechanical restraint; we have got past chains, sudden baths, shower-baths, and electricity. But it is important to remember that purges may be essential. I have known a person freed of his delusions by a very copious action of the bowels. You may need to purge so that you may be sure you are starting fairly. And in regard to sedatives, there seems to prevail a sort of healthy dread. In regard to half the patients I see in consultation the doctor says he is not giving anything to induce sleep. That may be right in principle, but no principle is right if you dogmatise on it too absolutely. If you have a patient suffering from sleeplessness, it is your duty to procure him sleep somehow. Nowadays the latest drug is always the best—veronal, or trional. Paraldehyde is the nastiest, and, therefore, in many cases, the best. Both bromide and chloral are given less than they were. Alter the diet, see that the patient does not take so much tea and coffee. If the patient has his last meal at 6 or 7 and goes to bed at 10.30, it is well to give a little hot soup, or something of the sort, with a little stimulant in it. Sleeplessness, especially in old age, is frequently relieved by stimulants.

Baths at one time were much used, and in two or three ways. The old brutal method was the "surprise bath," intended more as a punitive than as a therapeutic measure. In some cases, especially adolescents, a warm or hot bath, with a cold effusion to the head and neck, is useful; and very violent patients have derived much benefit from the prolonged bath, which can be readily arranged in any house. At Bethlem I have kept patients in such a bath eight or nine hours, and they frequently calm down quickly, when everything else has failed. In cases of chronic sleeplessness, it is good to add to the hot bath ¼ lb. of mustard to which has been poured a quart of boiling water, first letting it stand for ten minutes. Turkish baths are sometimes useful.

I have no experience of the subcutaneous injection of saline fluids.

Finally, I may say, I never, or very rarely, neglect to reason with my patients. (Dr. Savage gave instances of good results from this.) As to hypnotism, that is a subject large enough for a separate lecture. But hypnotism would do harm in patients who are emotional and already too sensitive. However, it is often successful in inducing sleep in those who badly need it. Sometimes delusions are shifted by hypnotic suggestion. Society is very much alert on the subject of prophylaxis, but we have not got so far as our American friends, and I do not think we ever shall: "Although it is desirable for the good of the community that only individuals who are mentally sound should propagate their kind, it is scarcely to be expected that the passage of laws similar to the one in Minnesota will in any degree do away with the possibility of marriages, even amongst those who are mentally defective. Hence we are left with only two methods by which these doctrines can be met, namely, ample provision for the poor unfortunates in institutions, or, if they be left at large, castration."

NOTE.—*A Clinical Lecture, by a well-known teacher, appears in each number of this journal. The lecture for next week will be by R. J. Kinkead, M.D., Dub., L.R.C.S.I., Professor of Obstetrics in Queen's College, Galway: Physician and Gynæcologist to the Galway Hospital. Subject; "The Consequences and Treatment of Laceration of the Female Perineum."*

ORIGINAL PAPERS.

RHEUMATOID ARTHRITIS

AND THE MORBID CONDITIONS WHICH SIMULATE IT; WITH SPECIAL REFERENCE TO PATHOLOGY AND TREATMENT. (*a*)

By ARTHUR P. LUFF, M.D., B.Sc., F.R.CP. (LOND.),

Physician to St. Mary's Hospital.

THE term "rheumatoid arthritis" is objectionable, as suggesting a causal connection with rheumatism. If, however, it is employed and understood as merely meaning an arthritis somewhat resembling some forms of rheumatism, the term may be retained, although the name "arthritis deformans" is less open to objection. I suggest, however, in this discussion that we retain the term "rheumatoid arthritis" owing to its long usage, as I am afraid that the description of the disease under another and less recognised name may lead to confusion.

Rheumatoid arthritis is held by some to be a very complex disorder which has many factors concerned in its etiology. I do not hold with this view. My own opinion is that although there are several infective diseases of the joints which somewhat resemble it, yet that rheumatoid arthritis is a distinct clinical entity, which, with care, may be distinguished from other forms of arthritis.

Rheumatoid arthritis is a constitutional disease, not a local one—the affection of the joints is only a part, although an important part, of the morbid process. It is, I believe, a disease due to the presence of micro-organisms which gain access to the blood in the majority of cases probably through some chronic catarrh of the alimentary tract, although the invasion may occur from the nose, pharynx, or air tubes. After gaining access to the circulation they find a suitable nidus for their growth in the joints, where they grow and propagate in the synovial membranes, ligaments, cartilages, and bones. As a result of their presence inflammatory changes occur which result in ulceration, erosion, destruction, and, coincidently as a rule, in hypertrophy also. During the active growth of these micro-organisms toxins are produced and discharged into the circulation, and by their action on the nervous system give rise to the nervous symptoms of the disease, while the toxins acting on the vasomotor nerves and the trophic nerves of the skin produce the local sweatings and pigmentation which occur in connection with rheumatoid arthritis.

That it is an infective disease is shown by the febrile disturbance, which, although not severe, always accompanies the early stages of the disease, by the rapidity of the pulse, the local sweating of the hands and feet, and by the progressive involvement of many joints. In its early stages it may very closely simulate subacute rheumatic fever, but it may be distinguished from it by not reacting to treatment wth salicylates. The disease usually commences in one joint, commonly one of the metacarpo-phalangeal articulations, and then rapidly spreads to other joints. Shortly after its commencement it is always polyarticular. The so-called forms of monarticular rheumatoid arthritis are, in my opinion, always traumatic in origin, and are due to degenerative changes set up within the joint as the result of chronic inflammatory processes which result in the disintegration and wearing away of the joint cartilage. It would be better, I think, to restrict to these forms the name "osteo-arthritis."

Rheumatoid arthritis occurs in two forms—acute and chronic. Both are due to the same infective cause and simply differ, as regards their clinical features, in the degree or virulence of the infection, or in the different results of a similar process attacking the joints at different ages. It is commoner in females than males. In the acute form it is generally met with in earlier adult life. The chronic form may be a later stage of the acute disease, or, as is more frequently the case, it is chronic from the first, and occurs especially in middle life and in females. In the latter it is specially prone to start about the climacteric period. Comparatively slight injuries of a joint, especially of a small joint, may lead to rheumatoid arthritis, and to an extension of the process to other joints in a symmetrical order. The injuries are frequently the outcome of excessive work and strain, especially in elderly and enfeebled persons with a diminished power of resistance, increasing with years, and with imperfect nutrition.

In the acute form the synovial membranes are primarily and mainly affected, while the ligaments are softened and infiltrated, presenting the well-known spindle-shaped enlargements of the joints. The cartilages are damaged secondarily, and it is not until the disease has assumed the chronic form that the signs indicative of destruction of cartilage become evident, accompanied with cartilaginous and osteophytic outgrowths.

Cases of Heberden's nodes represent the mildest degree of the disease. The nodes consist of little hard swellings of the finger joints, affecting almost entirely the terminal phalangeal, and are due to a very chronic form of rheumatoid arthritis. This type is more commonly met with in women than in men, and usually at or after the middle period of life. The nodules are due to enlargement of the ends of the bones, which are frequently covered by a pouch of the projecting synovial membrane, which acts somewhat as a bursa. The joints become swollen and tender. The cartilages are softened, and the ends of the bones are eburnated. The enlargements are osseous in character, but there may be a certain

---

(*a*) Opening of Discussion in the Section of Medicine at the Exeter meeting of the British Medical Association, August, 1907.

amount of increase of the periarticular fibrous tissues. After a time the disease usually becomes arrested, but the swellings remain, and eventually may cause no discomfort.

In the great majority of cases rheumatoid arthritis is a primary disease, but at the same time it is probable that in a small number of cases an antecedent attack of rheumatic fever, or of some form of septic arthritis, such as gonorrhœal arthritis, or even an acute attack of gout, may have left the joints in such a vulnerable condition that they may subsequently become the seat of true rheumatoid arthritis. Any debilitating condition may predispose to this disease, and especially of late years I have seen many cases of rheumatoid arthritis which have followed repeated attacks of influenza.

Treatment.—Rheumatoid arthritis, if left untreated, tends to spread from joint to joint, and produces progressive destruction of the joint tissues. Occasionally treatment fails to effect any arrest of the disease, and this is especially apt to occur in connection with the rheumatoid arthritis of the old. For the successful treatment of this disease it is essential that the treatment should be commenced while the disease is in its early stages; hence the importance of an early recognition of the malady, and of its distinction from gout and rheumatism. The treatment must be persevered in for a long period of time, generally a year or two, and during the treatment everything possible must be done to increase the patient's strength, and to maintain the general condition of nutrition at the highest possible level.

If rheumatoid arthritis is seen and recognised early in the acute stage it is curable. In the later chronic stages it is possible to arrest the disease, to remove the pain, and to secure greater movement of the joints; but it is not possible to bring the disorganised and deformed joints back to their normal state. It is remarkable, however, even in many chronic cases, what a considerable amount of improvement may be effected in the joints if suitable treatment is persevered with for a prolonged period of time.

The not infrequent mistake of diagnosing rheumatoid arthritis as gout, and the consequent placing of the patient on a restricted and spare diet, has undoubtedly led to the development of severe and incurable forms of the disease. It is essentially a disease that requires good and nutritious feeding, and I have seen many cases of rheumatoid arthritis which have gone thoroughly to the bad, through the initial error of mistaking the disease for gout, and treating it with a spare diet. The diet should be as liberal and as good as the patient can digest, and animal food should be partaken of freely, though not to the exclusion of vegetables. A moderate quantity of wine or stout should be taken with lunch and dinner. Any kind of wine that agrees with the patient may be taken, but perhaps a generous red wine, such as Burgundy, is the most suitable.

The drugs that I have found most useful in the treatment of rheumatoid arthritis are guaiacol and potassium iodide. I have now employed guaiacol in over three thousand cases, and as the result of my experience I do not hesitate to say that, if administered in sufficient quantities and for a sufficiently long period, it is capable in the great majority of cases of arresting the disease, of diminishing the size of the joints, and of permitting increased movements. It also relieves pain markedly. It is useful in both the subacute and chronic forms of rheumatoid arthritis. The guaiacol probably acts by inhibiting the growth of the specific micro-organism in the intestinal tract, and after absorption by combining with the bacterial toxins and assisting in their elimination. It is not to be imagined for one moment that the guaiacol renders the intestinal tract sterile, but just as the administration of cinnamon oil in cases of enteric fever exerts a restraining influence on the propagation of the typhoid bacilli, and renders them less capable of elaborating a virulent toxin, so, I believe, the guaiacol exercises an inhibiting effect upon the micro-organisms responsible for the production of rheumatoid arthritis. The iodide of potassium probably acts by promoting absorption of the hypertrophied fibrous tissues.

The most convenient form of administering the guaiacol is the carbonate in cachêts. This salt is a white powder which is free from the disagreeable odour, taste and irritating effects on the stomach of guaiacol itself. In the intestines it is slowly split up into guaiacol and carbonic acid gas. At first from five to ten grains of the carbonate of guaiacol should be given three times a day, and the dose should be increased by one to two grains each week until from fifteen to twenty grains are being taken in each dose. It is essential that this treatment should be continued for at least twelve months. The beneficial effects of the guaiacol are very much increased by administering at the same time a mixture containing potassium iodide; the depressing effect of the iodide should be counteracted by its combination with tonics.

The treatment that I have just detailed, is, in my experience, incomparably superior to the prolonged treatment for two, three, or more years of such cases with small doses of arsenic and iron, a method of treatment which still has many supporters.

After the treatment with guaiacol carbonate and potassium iodide of a very large number of cases of rheumatoid arthritis I am convinced that it is capable in the great majority of cases of arresting the disease, and so of preventing the frightful suffering connected with movements of the affected joints, a condition which is so common in cases of unrelieved rheumatoid arthritis. If the treatment is commenced in the comparatively early stages of the disease, then recovery with very little deformity may result; but even if after arrest of the disease much deformity results, very considerable mobility of the joints may be promoted by baths, superheated air, massage, and passive movements. It is frequently remarkable to find after such treatment what an amount of mobility and capacity for usefulness has been restored to joints which have been left in a severely deformed but quiescent condition.

The thermal treatment of the affected joints, either by means of baths, superheated air, or electric light baths, is most beneficial. Douche massage is the most effective form of treatment with hot water, and perhaps next to that rank peat baths and brine baths. Electric light baths, in which the affected joints are bathed in the heat and light rays reflected from a number of incandescent electric lamps, are also beneficial in many cases. Properly regulated movements and properly applied massage are of great use in overcoming the stiffening and fixation of the joints, and the muscular wasting in their vicinity.

Climate.—Dry heat benefits cases of rheumatoid arthritis, whereas damp cold increases the disease. Seaside resorts are not suitable for most cases. As a winter resort there is no better climate than that of Egypt.

ON
AUTO-DEFORMITIES OF THE FOOT.

By PAUL GALLOIS, M.D.,
Surgeon to the Paris Hospitals.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

THE perfection to which the hand has attained, making it an incomparable weapon in the struggle for existence has been in great measure rendered possible by the fact that the whole weight of the body falls upon the lower limbs. This weight is a matter of moment, seeing that it averages nine stone. If we suppose a foot 30 cm. long and 10 cm. in breadth at its widest part, this gives us 300 square centimetres, a surface of 300 q.c. for each foot, *i.e.*, 600 q.c. for the two. Every square centimetre of the plantar surface consequently has to support 100 grammes pressure. But if we take the imprint of the moistened foot on a plane surface, we find that only a part of the plantar surface comes into contact with the ground (1) the heel; (2) what has been called the anterior heel, constituted by the metatarso-phalangeal articulations and (3) by a band running along the outer border of the foot joining the anterior and posterior heels.

In standing, a man distributes the weight of his body fairly equally over the various parts of both soles, but this is by no means the case in walking, when necessarily each foot has to bear the whole weight in its turn, and in respect of each foot the weight is successively shifted from the posterior to the anterior heel. Let us assume for instance that the heel measures 6 cm. in length and 5 cm. in width, *i.e.*, 30 q.c. of surface area, it will be seen that at certain moments each square centimetre of the heel surface is called upon to support a weight of two kg. and this weight is notably increased in running and jumping.

Overstrain is a recognised cause of disease in any organ, and it is therefore by no means surprising if persons, who are obliged by their calling to walk a great deal or to stand the livelong day, ultimately suffer from various local disturbances in the feet thus subjected to excessive functional strain. This is so self-evident that it seems almost idle to insist upon the fact, but it has often happened to me to see patients suffering from troubles due to foot fatigue, the existence whereof had been ascribed by their medical advisers to various other causes. In some cases the pain &c., had been ascribed to rheumatism, this refuge of the destitute in diagnosis, and the patients were accordingly stuffed with salicylate. In others, surgical intervention had been proposed yet in all immediate and marked improvement usually followed a period of functional rest. It may therefore be as well, after all, to emphasise this pathogenesis and to discuss the various troubles due to foot fatigue as a whole, so that they may all be grouped under one head.

The term I propose is "auto-deformity of the foot." No doubt the term deformity is rather too strong for certain forms of foot fatigue, and in reality only applies to extreme cases, but on the other hand a milder term would fall short of the graver cases. "Auto-deformity," therefore, seems to me to express with sufficient precision the troubles determined in the bones of the foot by the excessive or unduly prolonged pressure of the weight of the body.

The foot rests on the ground on the anterior and posterior heels, but these two heels are but the pillars of an arch which has to support the direct weight of the body and transmit it to the calcaneum on the one hand and to the heads of the metatarsal bones on the other. This arch comprises the tarsal and metatarsal bones. The troubles induced by the weight of the body may therefore bear on (1) the calcaneum; (2) the tarsal bones; (3) the metatarsal bones; and (4) on the heads of the metatarsal bones which together form the anterior heel. It follows that we have to consider four distinct types.

(1) *Talalgia.*—Talalgia is characterised by a more or less troublesome pain on the plantar aspect of the heel. The pain is felt especially when standing, and may be elicited by pressure with the finger. It may persist even in the absence of pressure. Talalgia is especially frequent in persons who are constrained to the erect position possibly more than in those who have to walk a great deal. It has been described as "Policeman's Disease." It is also met with in bank messengers, shop employés, omnibus conductors and porters. It may be caused by irregularities in the boots throwing the weight of the body on a part only, instead of the whole, of the calcaneum. This bone, which is in this way subjected to a sort of perpetual bruising, becomes painful. Now, as a general rule, once a bone has become painful it remains so for a long time. Talalgia was attributed by Jacquet to gonorrhœa which he claimed gave rise to hyperosteosis of the calcaneum. I am not disposed to deny this possibility but I cannot say that I have ever observed an example thereof, although my attention was long since drawn to the question. On the contrary the perpetual bruising of the calcaneum appears to me to be a much more frequent cause. Some practitioners attribute the pain to rheumatism and have recourse to the salicylates which rarely give any result worth speaking of. Enterprising surgeons, having discovered the existence of abnormal prominences on the calcaneum, have gone so far as to propose partial resection of the bone. The conception of chronic bruising infers much milder measures. All we have to do is to get the patient to change his occupation if that be possible. Otherwise we must advise him to wear rubber soles inside his boots or to fix rubber heels outside, these articles being now on sale everywhere.

(2) *Tarsalgia.*—Tarsalgia occurs in all degrees of severity. In slight cases, which are the most frequent, patients complain of pain in the instep. If we run the finger over the arch in order to make out the exact spot it will usually be found on the inner side of the foot opposite the inter-articular spaces separating the first cuneiform from the scaphoid or the first metatarsal. This mild form of tarsalgia is generally ascribed to ordinary rheumatism.

A more advanced form is that of "adolescent tarsalgia," or flat-foot. Years ago Gosselin attributed it to contraction of the lateral peronei, but at present the theory of auto-deformity is generally admitted, and A. Broca in particular fully adopts this explanation in his treatise on children's diseases. Crushed by the weight of the body, the plantar arch gives way. Coincidently with the flattening of the foot the scaphoid is displaced inwards, and its normal prominence becomes unduly pronounced. In flat-foot of old standing the pain is often but slight, and patients suffering therefrom, in spite of the deformity, are very good walkers. This form is very frequently met with in Arabs. Tarsalgia with flat-foot is particularly frequent at adolescence at a time when the body is rapidly increasing in size and weight, and the bones of the foot become lengthened, although retaining an infantile consistency. The treatment consists in supporting the plantar arch either by insisting on boots that hold the foot well together, thickened on the inside, corresponding to the arch, or by using pieces of cork or rubber modelled to the normal arch, or metal supports of the same kind. Simple or comparative rest, however, often suffices to effect a cure.

The grave form of tarsalgia is that associated with tabes. The mechanism is the same, but as the bones in ataxic subjects are abnormally fragile they do not merely slide one over the other, but they give way and break, with a sudden yielding of the arch, the fractured ends uniting with deforming callus.

(3) *Metatarsalgia.* This type of crushed foot is well-known to military surgeons under the name of "forced foot." It is an acute accident characterised by sudden painful swelling of the foot over the metatarsal bones. Skiagraphy, confirming what had already been suspected, has enabled us to distinguish a fracture usually of the fourth metatarsal bone.

It may be asked why this metatarsal bone should be affected in preference to any of the others. A fracture of the internal or external metatarsal bone would be easier to understand but the first metatarsal bone is very strong and the fifth is also fairly resistent, moreover it rests its whole length on the ground as shown by the footprint. It follows that these two metatarsal bones are likely to resist the crushing influence. As to the three intermediate metatarsals they are approximately of the same size, yet the fourth is, if anything, rather smaller. Moreover, we must bear in mind that the metatarsal bones taken together represent an arch, not like the instep antero-posterior, but transverse. It is the heads of the first and fifth metatarsal bones that rest on the ground, as anyone can see for himself if he examines a normal plantar surface. The skin over them is thicker and the fatty padding is more marked. On dissection we find bursæ over them, indicating that these are the two bones that do most of the work. Now when the foot is fatigued by long marches, as in soldiers who have, moreover, to carry a knapsack, this transverse arch gives way, and of the three middle metatarsal bones which are less protected and less strong than the others, the first to come into contact with the ground is the fourth, hence the frequency with which it is fractured.

(4) *Morton's Neuralgia.* In the affection known under this name it is again the fourth metatarsal bone that is the seat of pain, opposite to its articulation with the phalanx. When chronic the mechanism is the same as in "forced foot." There is also some relaxation of the ligaments binding together the metatarso-phalangeal articulations, with flattening of the transverse arch, bringing the head of the fourth metatarsal bone into contact with the ground, and as it is less protected the chronic bruising to which it is subjected provokes an abnormal pain similar to that in the calcaneum in ordinary talalgia, in other words it is an anterior talalgia.

The theory of neuralgia infers that the nerve filaments are compressed between the heads of the fourth and fifth metatarsal bones and the advice usually given is to wear wide boots with thin soles, or light slippers. But in reality it is better to have thick soles, thus distributing the pressure over the anterior heel and keeping the fore part of the foot rather tightly bound so as to reform the arch of the anterior heel. In some instances a simple ribband tied round the metatarso-phalangeal articulations will suffice to give relief.

Rest is obviously the best way to effect a cure, but we must remember that, just as in talalgia of the calcaneum, the pain induced by bruising of bone is usually very persistent and subsides but slowly. Surgical operation, resection of the head of the painful metatarsal bone, has been proposed in Morton's neuralgia, just as in talalgia.

It will be seen then that overstrain of the foot determines various deformities of the bony framework of the foot. By considering them together we are better enabled to appreciate the mechanism of their pathology. It is important to recognise them properly, if only to avoid useless medical treatments and uncalled-for surgical interventions. They may be improved by various modifications of the foot gear, by massage, electricity, baths, and the administration of phosphate of lime, but we must at all times bear in mind that there is really only one effectual means, viz., rest.

THE MEDICAL ASPECT OF DENTAL CARIES IN CHILDHOOD. (*a*)

By G. F. STILL, M.A., M.D., F.R.C.P.,

Professor of Diseases of Children, King's College, London: Physician for Diseases of Children, King's College Hospital; Assistant Physician to the Hospital for Sick Children, Great Ormond Street.

Caries of the teeth is an important cause of ill-health in children, and one which is apt to be overlooked; the converse is also true that ill-health in children is a cause of dental decay. Decayed teeth interfere with the proper assimilation of food, and such interference is most serious in childhood when growth and development, physical and mental, should be at their greatest activity. Any widespread prevalence of dental decay in childhood is a menace to our national physique. A series of observations taken amongst children brought to hospital for other conditions showed that 82·7 per cent. of children between 5 and 12 years of age had decayed teeth, and 39·8 per cent of children between two and five years old. Some of these children had 10–15 carious teeth.

Parents as well as medical men ought to know how much a child's health may suffer from decayed teeth. The commonest evil therefrom is digestive disorder, and this in a child is often shown by loss of flesh, loss of appetite, enlargement of the abdomen, and sometimes by frequent pains in the abdomen. Anæmia is also sometimes due to dental caries, perhaps in consequence of chronic poisoning from the foul condition of the

---

(*a*) **Abstract of paper read before the Dental Section at the Exeter meeting of the British Medical Association, August, 1907.**

teeth. Decayed teeth also form a nidus for micro-organisms which may set up inflammatory disorders in the mouth or pass into the blood or into the neighbouring glands and produce more serious disease. It has been thought that tuberculous disease of the glands in the neck may arise from infection from decayed teeth; the tubercle bacillus has been found in decayed teeth, and enlargement of glands is very frequently associated with decayed teeth, but it is very uncertain how often any tuberculous infection is due directly to the teeth, for there are other and probably much commoner sources of infection; but there can be little doubt that indirectly by causing swelling of the glands dental caries is a powerful predisposing cause of tuberculous infection of these glands.

Decayed teeth are also a cause of frequent headaches in some children, and occasionally give rise to more troublesome nervous disorder such as habit spasm, and in a few recorded cases even epilepsy.

Lack of proper cleaning of the teeth is one factor, but not the only one, in the production of dental decay. Considerably more than 50 per cent. of children of the hospital class at the school age have never cleaned their teeth in their lives. But it has been shown that children of the well-to-do classes are just as liable to dental caries as the poorer and less well-cared for children, and whilst the most scrupulous cleanliness will not always prevent decay, complete ignorance of a tooth-brush is not inconsistent with a perfect set of teeth.

There are differences in the teeth of different children; in one the enamel is thicker and more perfectly formed than in another, and this difference may be congenital and perhaps peculiar to particular families so that the children of one family may have teeth more resistant to decay than those of another family; but imperfect development of the teeth, particularly of the enamel, may be due to preventable disease, namely rickets: and any profound disturbance of nutrition in infancy, such as is produced by improper feeding, may interfere with the perfect development of the teeth and so make them more liable to decay.

Diet has some influence in producing decay of the teeth after they have already been cut, but probably this influence is chiefly indirect; any food which causes digestive disorder, thereby alters the secretions of the mouth so as to favour the action of bacteria in producing fermentation and eroding the enamel. Sweets, which are generally supposed to harm the teeth, probably do so only in this indirect manner, for, given at wrong times and too frequently they are specially apt to upset digestion.

The prevention of dental caries must date from earliest infancy. If 39·8 per cent. of children between two and five years of age have decayed teeth, it is evident that the mischief is often present before the school age, and no dental inspection of schools can take the place of parental care in preventing this evil. Proper feeding in infancy and the prevention of rickets and of digestive disturbances in early life are of prime importance. The teeth from their earliest appearance, should be cleaned twice daily, especially in the evening.

There is a most erroneous and mischievous idea current that decay of the first teeth is of little importance, whereas it is probably more liable to injure the general health and the physical development then than at any other period of life. If parents would take their children regularly to a dentist for inspection two or three times a year, and if dentists would see that decayed teeth were stopped whenever possible, there would be less ill-health and difficulty of digestion in early childhood, and probably also less decay in the permanent teeth.

THE OUT-PATIENTS' ROOM.

ROYAL FREE HOSPITAL.

Patient on whom Colotomy had been performed for Intestinal Obstruction.

By J. P. LEGG, M.S., F.R.C.S.

MR. LEGG showed a patient on whom he had performed colotomy for chronic intestinal obstruction more than a year ago. She was a woman, æt. 44, who had suffered from gradually increasing constipation, abdominal pain, and distension during several months previous to the operation. She had lost flesh also to some extent, but was not emaciated. On examination of the abdomen, peristaltic movements of the descending colon and sigmoid were very obvious, and whenever a wave of peristalsis occurred she complained of a certain amount of discomfort and wind which could be heard gurgling in the intestine. Deep down in the left iliac fossa a definite hard mass was discovered which was easily felt in Douglas's pouch on making a vaginal examination. She had had no mucoid or blood-stained discharge from the rectum, which was found to be quite healthy. At the operation it was evidently impossible to do an excision of the growth, and therefore a colotomy into the highest part of the sigmoid was done. As the symptoms were not very urgent, the bowel was not opened till the seventh day. Mr. Legg showed the case, and pointed out the several indications for doing a colotomy, the advantages and disadvantages of the operation. As regards the indications, he said, this woman furnished a typical example of a patient suffering from intestinal obstruction with an irremovable growth, and it was important to remember that the obstruction was the chief factor in influencing the surgeon to do a colotomy. Many patients had an irremovable growth in the rectum, but this fact alone was not a sufficient indication for the performance of this operation. Before advising such patients to have a colotomy, the symptoms which the malignant disease was causing had to be carefully considered. Thus, if a growth was extensively ulcerated and there was a constant discharge of bloody mucus from the anus, or if the patient was suffering from diarrhœa and very severe pain caused by the ulceration colotomy was frequently of great value in relieving the symptoms. One had also always to remember that at most colotomy was only a palliative operation, and although patients frequently obtained a certain degree of control over the artificial anus, yet that control was never perfect and the presence of the colotomy might add to the discomforts of the patient without relieving the symptoms if it was done in unsuitable cases. In doing the operation, an essential feature was to obtain a good spur separating the upper from the lower opening in the bowel. Then, it should be done through as small an incision as possible, and the lowest part of the descending colon or the highest part of the sigmoid should be fixed to the parietes, thereby lessening the chance of the formation of a ventral hernia and of prolapse of the intestine through the incision. In order to obtain a good spur, a V-shaped loop of the intestine must be brought out on to the abdominal parietes and the meso-sigmoid transfixed by a suture, which also fixes the two sides of the incision to each side of the mesentery, and in order to increase the chances of the patient having more perfect control over the passages of the fæces, it was a good plan to split the muscles of the abdominal parietes in the direction of their fibres rather than to cut straight through them. Mr. Legg, however, was inclined to attach more importance in this respect to obtain a good spur separating the two openings in the bowel; both openings were circular in shape and were completely surrounded by the muscular coats of the intestine, and if the surgeon's finger was inserted into the orifices it was easy to feel the grip or contraction of the muscle fibres. As in this patient, the skin around a satisfactory colotomy should be quite healthy, not red or excoriated, and, as in this patient, the colotomy should not require dressing more than twice a day. To further add to the comfort of the patient, it was a very good plan to irrigate the lower piece of bowel, namely, that to which the growth was still connected, either through the lower colotomy opening or through the anus. By this means the discharges from the growth were washed away every day. A belt of some sort was necessary, and he thought the most convenient and useful, most easily kept clean, was one in which there was a thick glass reservoir covering the openings into the bowel Plugs fitting into the apertures should not be used, and if the operation was done as described in this case there was no tendency for a stricture of the orifices to form. The woman as now seen was in very good health; she had been able to do her work as a caretaker in a large warehouse for the past seven months. The skin around the colotomy was quite healthy, there was no prolapse, and only a slight amount of bulging of the scar. The colotomy, she said, acted two or three times a day, and she knew when it was going to act if the bowels were not relaxed from any cause, and this, she asserted, rarely happened. On making a vaginal examination the growth did not appear to have extended, and there was no evidence of secondary growth in the liver, although it was more than a year since the colotomy was done. Mr. Legg pointed out that carcinomata of this type found in the sigmoid were not so malignant as other carcinomata of the rectum, and, as a rule, can be excised with or without a colotomy; in this particular instance the growth was not excised because it had infiltrated an adjacent portion of small intestine and was closely bound down to the pelvic walls. He added that such growths were the commonest cause of chronic intestinal obstruction in people æt. over 40.

OPERATING THEATRES.

KENSINGTON GENERAL HOSPITAL.

Nephropexy: Spinal Analgesia.—**Mr. Canny Ryall** operated on a woman, æt. 40, who had been admitted suffering from movable right kidney. For some years the patient had had all the cardinal symptoms of this affection, but the usual nervous symptoms, which are so often met with in these cases, were absent. The patient was seated on the operating table with the shoulders well arched, the skin over the lumbar spinous processes, which had been previously prepared, was now thoroughly swabbed with alcohol, then frozen with ethyl chloride. A puncture was then made with Mr. Canny Ryall's puncture knife and the platinum iridium needle of his apparatus for spinal analgesia was next inserted into the spinal canal through the median plane; cerebro-spinal fluid at once flowed in a good stream, and 10 cc. were withdrawn. A 1 per cent. solution of novocain with synthetical suprarenin was injected. The patient was kept seated in the vertical position for five minutes, and then placed on her left side with a sand-bag under her loin, and the usual oblique incision immediately below the last rib was made. The kidney having been rapidly exposed and drawn through the wound, a narrow strip of the capsule was raised from the lower to the upper pole of the kidney and twisted into a cord. A blunt needle was then passed beneath the skin from without inwards over the last rib, the twisted portion of capsule was next threaded through the eye, withdrawn from within outwards, and securely fixed to the adjacent muscular tissue. It was then seen that by this means the kidney was well slung. In addition the remaining part of the capsule on its posterior aspect was divided transversely: this enabled four flaps of the capsule to be raised, which were fixed with catgut to the adjacent muscles. It was now apparent that the kidney was securely placed in a high position. The wound was then closed. Mr. Canny Ryall said that the first point to be noticed was the sleepy condition of the patient when she was brought into the theatre: this was due to her having previously had two injections of scopalamin and morphia, given, the first two hours before, the second one hour before the operation. In some cases he gave three injections. He pointed out that he now always uses scopalamin and morphia in conjunction with novocain for operations on the gall bladder, the stomach and kidneys, also for hysterectomies, and where it is anticipated peritoneal adhesions exist. In the first place the lumbar puncture should be made in the median line, and not to one side of it, as it is sometimes done by surgeons in this country. If the lateral method is employed semi-analgesia or imperfect analgesia may be the result; the advantages in his opinion of median puncture are that one always gets perfect analgesia, and there is no risk of injuring the cauda equinia. He said he was the first surgeon in this country to use novocain for the production of spinal analgesia; also synthetical suprarenin in conjunction with it, as well as scopalamin and morphia as an adjunct for higher operations in the abdominal cavity. He stated that he could not speak strongly enough in favour of spinal analgesia, for, of all methods for combatting shock, none could compare with this one. It was particularly indicated in patients suffering from heart disease, diabetes, alcoholism, for aged people, for those suffering from shock following injuries to the abdomen and lower extremities, or in operations such as excision of the rectum, strangulated hernias, hysterectomies, amputations of the thigh, prostatectomies, and to ward off the shock which so commonly follows these operations. He had performed all these operations with analgesia produced by this method, and was particularly struck by the absence of subsequent shock. As regards drugs for spinal injection, surgeons had novocain, stovain, tropococaine and alypin' to choose from, all of which had been discovered within the last few years. Novocain, in his opinion, was far superior to any of the others. He had used a 10 per cent., 5 per cent., 2 per cent., and now only employed a 1 per cent. solution of novocain. In general anæsthesia the rule was to use as little ether or chloroform as possible, and going on these lines for spinal analgesia, he now worked with a 1 per cent. solution of novocain in conjunction with synthetical suprarenin, which gave perfect results. He considered that the duty of injecting the patient should fall to the lot of the ordinary anæsthetist, provided that he (the anæsthetist) was well versed in aseptic measures, and the duty of the anæsthetist after the injection would be to keep the patient's attention occupied by continuous conversation. Mr. Canny Ryall would advise chloroformists to practise lumbar puncture on the dead body before performing it on the living; he said spinal analgesia should never be carried out in acute septic or infective cases.

FRANCE.

Paris, Aug. 11th, 1907.

Exophthalmic Goitre.

The first complete description of exophthalmic goitre was due to the celebrated physician, J. P. Graves, and to a German doctor, Basedow; consequently this affection is frequently called Graves', or Basedow's, disease. These two authors, whose publications date as far back as 1840 and 1843, had, however, some predecessors amongst whom may be cited Parry (1825) and Flagani (1802), an Italian. In Italy it is still called Flagani's disease.

In France, the clinical lectures of Trousseau and the publications of Charcot, Rendu Marie and Bellet, made known the symptomatology of exophthalmic goitre.

Goitre, exophthalmia, tachycardia, trembling, such are the four essential signs of Graves' disease. These symptoms are not, however, of equal value, for in the attenuated form certain of them may be absent; but the most constant is tachycardia or cardiac palpitation.

Exophthalmic goitre is most frequent in women; rare before puberty, it is exceptional after the age of fifty.

Cardio-vascular troubles are generally the first symptoms observed; the others develop little by little.

In very rare cases, the initial symptoms set in very suddenly, but even here, intelligent questioning of the patient will reveal that the malady had already set in by slight signs which had passed unperceived.

Yet there are on record certain cases where the attack came on suddenly from violent emotions. Trousseau relates the case of a woman who had lost her father, to whom she was greatly attached. In one night that the patient had passed in weeping, she felt all of a sudden her eyes swelling so as to prevent her from closing the eyelids, the thyroid gland developing considerably and violent palpitations. Dieulafoy mentions a similar case provoked also by a violent emotion. However, in the immense majority of the cases, the disease sets in gradually.

Hypertrophy of the thyroid gland generally begins insidiously, and it is not until after some months that the patients remark that the front of the neck is somewhat enlarged. It rarely attains a considerable volume, and sometimes it is hardly visible, palpation alone permitting to assure oneself of the extent of the hypertrophy. Both lobes of the thyroid gland may be affected, but that on the right side is always the larger. In any case, the degree of consistence and the volume vary from one moment to another; an attack of palpitations, deep emotion, anger, are sufficient to provoke a notable increase in the dimensions of the gland. The tumour is pulsatile, animated with a movement of expansion at each contraction of the heart. These pulsations are a distinctive sign, as they are not found in ordinary goitre.

Exophthalmia is the most inconstant of the four cardinal signs of the disease, but where it exists it does not fail to draw immediate attention by the strange look it gives to the physiognomy.

Many patients, says Trousseau, affected with exophthalmic goitre come to consult for palpitations of the heart; but the strange look on their faces, seeming to express both astonishment and fright, will soon attract attention and render the diagnosis easy.

When the exophthalmia is very accentuated, complete occlusion of the eyes becomes impossible even during sleep; the cornea remains exposed and is only protected by the lacrymal hyper-secretion which is generally produced; but if this secretion ceases, the cornea dries up and sometimes becomes infected and ulcerates. Grave lesions may be the result.

In every patient suffering from Basedow's disease, three symptoms should be sought for which generally accompany exophthalmia, and although they are not always present, they are of a certain importance. The most frequent of these symptoms is the sign of Graefe, which is characterised by a want of synergia of the movements of the eyelids and the ocular globe; when the patient looks up or down, the movement of the eyelid is slower than that of the eyeball. The sign of Stellwag is less frequent; it consists in a considerable enlargement of the palpebral slit and in the incomplete occlusion of the eyes when the patient thinks he has closed them.

The third symptom, or sign of Möbius, is characterised by the difficulty or impossibility of converging the eyes.

The cardiac troubles drew the attention of the first authors, and in reality they constitute the most constant symptoms and in general the most precocious of exophthalmic goitre; the patients nearly all begin by complaining of palpitations, which are sometimes violent and prolonged, causing a bulging forward of the thoracic wall and the heart-beat against the chest is so considerable that it can be heard sometimes at a distance.

These palpitations become more frequent and stronger under the influence of moral emotions or effort. The pulsations of the carotids are stronger than in the normal state, and are a cause as well as the jugular veins, of the bruit perceived over the thyroid tumour

They are not permanent, but come on in the form of attacks, provoked by moral emotions and efforts. They are generally accompanied by a temporary dilatation of the heart. True hypertrophy of the heart is rare. Auscultation reveals an acceleration of the heart-beats and frequently a souffle extracardiac.

Trembling in exophthalmic goitre was described by Charcot and Pierre Marie. The patient, said P. Marie, is in a state of continual vibration, standing or sitting, the body is animated with a perpetual tremulation, and all the surface of the body is the seat of a kind of general palpitation of a very singular character. It affects the body, head, and, above all, the hands.

Sometimes, it is localised to the extremities, the hands; but the whole hand, and not as in hard drinkers, individual trembling of the fingers.

Other very important symptoms, although secondary and inconstant, may be found grouped around Graves' disease. Those belonging to the nervous system take the first rank: paresia, asthenia, paraplegia, pseudochorea, cephalalgia, rachialgia, neuralgia. Psychic troubles are nearly always constant. From the very beginning, says M. Boix, frequently before the cardinal symptoms have commenced to reveal themselves, the patients show signs of a particular mental condition. They are tormented by an indefinable agitation; their sensitiveness knows no moderation, marks of joy and sadness are excessive, and without proportion with the motives and even without motive. They pass without transition from enthusiastic gaiety to bitterness and discouragement. Ideas rush upon them in quick succession, and are ever changing; they speak with volubility, and are haunted with an uncontrollable desire to be doing something; they cannot keep quiet. At the same time, their character sours; they become difficult to live with. Impatient and irascible, they break out at the slightest contradiction; they are never satisfied, nor ever grateful for any services rendered them.

GERMANY.

Berlin, Aug. 11th, 1907

At the Verein für Innere Medizin, Hr. Hans. Hirscfeld showed preparations from a case of

Poisoning by Chlorate of Potash.

He said the preparations showed not only the known changes in the red blood corpuscles, but also changes in the white corpuscles that had not been hitherto described. The case was that of a girl, æt. 19, who had taken 20grm. of chlorate of potash on June 4th, and was admitted into hospital two days later. She was dull, had the typical blue-grey colouration of the skin, the corneæ were icteric, the urine scanty, dark brown, and containing a large quantity of methæmoglobin. After venesection, performed at once, followed by transfusion of human defibrinated blood, there was slight improvement. During the following days the excretion of urine was scanty, œdema and vomiting were present, and there were also signs of cardiac failure. The treatment consisted in saline infusions, hot baths, injections of pilocarpine and inhalation of oxygen. Death took place on the ninth day after the poisoning. On the first day, the red blood corpuscles showed discolouration of the stroma, within, small nuclei containing a large quantity of methæmoglobine; many had escaped, and were floating free in the blood plasma. On the fourth day of observation red cells were no longer seen undergoing the process of destruction; the number of erythrocytes, 1,500,000; of leucocytes, 15,000; neutrophile hyperleucocytcsis, also myelocytes. Repeatedly leucocytes with polymorphous nuclei were observed, the remains of red blood corpuscles. Besides this, cells with distinct alteration of the neutrophile granula were seen (swelling or destruction); further, neutrophile elements, with clubbed nuclei, *i.e.*, a number of globular structureless nuclei intensely coloured; such cells had never been described as seen in the blood, but in pus, and especially in that of gonorrhœa. Further, quite small cells with round nuclei containing neutrophile granula, which were identical with Ehrlich's pseudolymphocytes. Ehrlich had only once seen them in the blood—in a case of hæmorrhagic smallpox. Lastly, neutrophile cells containing polymorphous nuclei, were very singular, as also some large mononuclear elements which contained from one to several large colourless vacuoles. The speaker believed these were cells that had eaten up red blood corpuscles or their remains; the vacuoles remaining at the spot where this nutrient material lay. It was in favour of this that here and there small fragments containing hæmoglobine still remained in them. That these structural anomalies which had been already described as being present in pus were present also in the blood had not before been recorded.

Hr. Hans Kohn demonstrated preparations from a case of

General Melanosarcomatosis

(liver, lungs, pleura, spinal column, skull, brain, suprarenal capsules, intestine, and uterus) in which the starting point from a pigmented organ was not demonstrable (the suprarenal capsules contained only metastases), and two nævi could not be looked on as point of origin as they had a perfectly harmless appearance and other pigmented organs, such as the choroids were healthy. For this reason the question pressed as to whether if such a starting-point in a pigmented organ was necessary, the pigment may not be developed in the organ itself, as a result of some chemical process. That pigment may develope from chemical causes, Addison's disease and other cachectic pigmentations showed. One might think that a chemical cause perhaps a special ferment, might lead to the formation of a pigment out of the albumen of the tumour. It was in favour of this that in similar cases many tumour nodules were strongly pigmented, many only in part, and others not at all. The liquefying also of many nodules spoke in favour of a fermentive process. V. Fuerth also had made a certain ferment responsible and had assumed that tyrosinase, acting on tyrosine and other hydrochloric substances of the aromatic series formed pigment, and Gessard claimed that he had found tyrosinase and tyrosine in a melanotic carcoma of a horse.

Hr. Westenhoeffer remarked that he had seen a similar case along with V. Leyden. It led a rapid course, and terminated fatally under febrile symptoms in three weeks. What was the course in the case shown?

Hr. Kohn replied that the case ended fatally after a six to eight weeks' febrile course.

AUSTRIA.

Vienna, Aug. 11th, 1907.

Secondary Vaccination.

At the Gesellschaft für Innere Medicin Friejung presented a four-year-old child with a perfect vesicle on the face, the result of contact with her younger brother. The transmission seems to have taken place thirteen days after the vaccination of her brother, which was looked on as very late, and rather remarkable.

Meningo-Cocci Serum.

Jehle showed a case of cerebro-spinalis which he had successfully treated with meningo-cocci serum, according to Paltauf's theory. About seventy-two hours after the disease had declared itself lumbar puncture was made and 20 cubic centimetres of cloudy purulent matter withdrawn which, the microscope demonstrated, held large quantities of meningo-cocci. Twenty cubic centimetres, *i.e.*, the whole of the fluid, was intra-durally injected, after which the temperature fell within twelve hours from 40° centigr. to 36.4° centigr., but the stiffness in neck remained unchanged. The fluid from the lumbar punctures which were made on the next two days was free from all trace of the cocci as far as the microscope could discern, but by cultivation a few tiny colonies presented themselves. About forty-eight hours after the first injection the temperature again rose to 39.2° centigr., but on the following day fell to 36.8° centigr. In the evening of this same day the temperature rose again to 39.3° centigr. with increased stiffness of the neck. Another serum injection (freed from the cloudy purulent matter), containing 30 cubic centimetres this time, was injected which brought the temperature to a normal state, relieving all the stiffness from the neck and, twenty-four hours afterwards, the patient was apparently quite well.

Forty-eight hours after the second injection the fluid extracted by lumbar puncture was perfectly clear and free from any morphological element or bacteria. On the sixth day of the disease, or three days after the first serum injection, an interesting eruption appeared on the upper part of the left arm covering an area as large as the palm of the hand, and resembling Herpes, which rapidly spread on the following day. The vesicles contained a purulent fluid which contained the meningo-cocci, when examined by the microscope.

Escherich thought these meningo-cocci found in the vesicles had found their way from the circulation as a form of metastasis irritating the trophic nerve and producing the vesicle. He said this experiment was no novelty as he had been practising this for some time with perfect success. He had used different meningo-cocci sera, but more particularly Jochmann and Ruppel's better known to the Austrian Sera-therapists. He usually injected 10 to 20 centimetres intra-durally at the earliest moment after diagnosis was complete and before any cerebral destruction took place. In slight or moderate cases the favourable effects are early observed by a rapid fall of the temperature, disappearance of the delirium, and relaxation of the stiffness in the neck—sometimes a perfect recovery within 24 hours. In all cases local disinfecting of the nasal and buccal cavities should be thoroughly carried out.

Disease in the Quadrigemina Region.

Infeld next showed specimens taken from subjects who had suffered from morbid change in the brain in the neighbourhood of the quadrigemina. The first was taken from an old man, æt. 70, who had suffered from an injury to the head when five years old. In life there was paralysis of the trochlear and oculo-motor muscles on the left side, while the right side of the body was atrophied with spastic paresis, disturbed sensibility, and chorea from movements of the paralysed side. There was also hyperflexibility of the fingers, clonic reflex of right leg, but the reflex was absent on the right side of the abdomen, while Babinski phenomenon could not be excited.

The *post-mortem* confirmed the diagnosis of tubercle in the left red neucleus of the quadrigemina.

The second preparation was from a young woman, æt. 25, who had suffered from left otitis, subsequently undergoing operation for radical cure. In life she complained of a numb condition of the left side, diffuse bronchitis, tubercle in the apex of left lung, congestion of the papilla in the fundus of eye, stiffness and feeling of pressure in the neck, vaso-motor disturbance in the skin, hyperæsthesia of the lower half of trunk, marked ptosis of right eye with slight facial paralysis on same side, right papilla wider than left, but reflex lost in both eyes. At an earlier period in the disease, there were right-sided hemianopsia, paralysis of lids, ataxia in the upper extremities, loss of patellar reflex in left leg, but only reduced in right, and no Babinski phenomenon. For two years she had suffered from headache and giddiness, and the last year with vomiting. The *post-mortem* revealed tubercle in the quadrigemina.

HUNGARY.

Budapest, August 11th, 1907.

At the recent meeting of the Budapest Interhospital Association Dr. Bauer exhibited a case of

Sclerosis Multiplex Congenita.

All the chief symptoms consisted in the greater spasticity of the lower and less spasticity of the upper limbs. The deep reflexes were exaggerated. Besides, there was in some measure tremor present, which seemed to be more expressed at intended movements. We are encountering the pathological picture of sclerosis multiplex often enough in old individuals, but it is very seldom seen in children, especially when we can easily diagnose that it is congenital.

Dr. Keller exhibited a case of

Paralysis Progressiva Juvenilis.

In a patient, æt. 19 years, acquired syphilis could be excluded; according to probability nervous disorder of other nature could also be regarded as excluded. Thus we had to assume that the paralysis affected a man who had inherited the tendency, and in whom the disease occurred, on the ground of unknown influences.

Dr. Ivànyi read a paper on the

First Manifestation of Syphilis on the Cheek.

Also in this case, the patient, on account of the extragenital manifestations having been overlooked, came under proper treatment when already infected with grave symptoms. The patient, a female servant, æt. 24 years, was admitted to hospital with general papular syphilides, which had existed for three weeks, while the primary sclerosis on the right cheek and the glands, the size of nuts, on the right side of the neck, had been seen for three months. The patient was not attended to up to this time. The cause of infection could not be detected.

A Case of Spastic Spinal Paralysis.

Dr. Salgo exhibited a patient, æt. 31, who fell ill three years ago with similar symptoms as those complained of at present. Three years ago, after finishing a systematical antisyphilitic cure, the patient has improved so far, that he could follow his vocation without any trouble. At present he can walk only with the aid of a stick, and even so his gait was unsteady, he could not bend his knees, his paces were short, and the feet almost stick to the earth. The knee was stiff, and during the act of walking not only the muscles of the lower limbs became strained, but the exertion was apparent even on the upper limbs, too; besides, walking was uncertain, and on the whole the complexity of symptoms showed that type, which is called by Charcot and Erle, the spastic paretic gait. Beside this paresis of the lower limbs the atrophy of the muscles were absent, even in a lying posture the muscles were able to show considerable strength.

Further, any lesion of sensation and urinary difficulties were absent. However, the general exaggerations of the knee jerks was striking; a slight knocking of the knee tendon resulted in great elevation of the foot. The touching of the Achilles tendon resulted in a clonic spasm. The passive dorsal flexion of the foot was followed by a long-standing clonus. If the sole was touched the toe had a dorsal flexion. (Babinski's symptom).

From these positive and negative symptoms the diagnosis of spastic spinal paralysis was drawn.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

BELFAST.

Paintings by a Medical Man.—An interesting exhibition of pictures by the late Dr. James Moore has just been opened in the Municipal Art Gallery at Belfast. Dr. Moore was one of the foremost surgeons in Ulster some thirty years ago, and at the same time an artist of no mean ability. It is said that he never went to a country consultation without carrying a colour-box and sketching-block, with which he filled in many a spare hour when waiting for trains, etc., so that when he died in 1883 he left behind him a great number of sketches and paintings, chiefly of landscape and seascape in Ulster. It is, indeed, by his sketches and by the many tales of his ready wit that he is now remembered. He was a frequent exhibitor at the Royal Hibernian Academy, and was elected an honorary member of that body. He was probably more appreciated in Dublin than in his own city, if one may judge from the story told of a hospital bazaar, for which a lady persuaded him to do several small water-colours, which he expected would sell for about a guinea each. Some time afterwards he met the lady who, with a pleased smile said, " Oh, Dr. Moore, I have sold all your pretty pictures and I I got half-a-crown apiece for them." Few of his pictures have come into the market; but one, "Slieve Bernagh, Mourne Mountains," has lately been acquired by some of his old friends, and has been presented to the Belfast Art Gallery as a permanent memorial of Dr. Moore.

The Corporation and Physical Degeneration.—Some months ago there was some stir in Belfast over a placard issued by the Corporation, and posted all over the city, calling the attention of the people to the conclusions of the Royal Commission on Physical Degeneration on the subject of the abuse of alcohol. The Vintners' Association protested at the time, but after much wordy warfare the placards were eventually issued. But the Vintners still protested, and appealed to the Local Government Auditor, who had disallowed a payment of £10 10s. for the placards, on the ground that he can find no statutory authority for the payment. He has, therefore, surcharged the three members of the Corporation who signed the cheque for the amount, and it now turns out that one of the three was a leading member of the Vintners' Association—a truly Gilbertian conclusion to the affair!

LETTERS TO THE EDITOR.

THE COLLECTION OF DEBTS BY DEBT-COLLECTORS.

To the Editor of The Medical Press and Circular.

Sir,—I ask space for a few remarks on the letter of " Medicus " and your comments on it. The collection of debts by debt-collectors is very common, and in most parts of the United Kingdom solicitors will generally undertake to collect debts at a percentage—usually 25 per cent.—relieving the client from all risk. But, of course, this is only done when the medical man places a number of debts in the hands of the same solicitor for collection. Against debt-collectors generally I have nothing to say; but I fancy what Judge Mulligan said was that when a debt-collector was not a solicitor he would not allow him to plead a cause in his Court. In this I think he was right, whatever the practice of his predecessor may have been. When a proceeding has to be taken in Court and the plaintiff cannot attend in person (or at all events, by his clerk, foreman, &c.), I think he should be required to employ a solicitor. The debt collector cannot be in a position to prove the debt unless he produces his employer's books, &c., for the purpose. That the doctor told him it was due and asked him to recover it is not evidence, and it would be unsafe to accept the evidence of a debt-collector, whose remuneration depends on his success, as to verbal admissions by the debtor unless there was some one to examine him.

But I apprehend that the debt-collector more frequently appears on the subsequent application for an instalment order or a committal order, though even here I am doubtful whether it ought to be permitted, He makes inquiries as to the debtor's means and knows much more about them than the creditor probably does; and he is the proper witness to show what instalment the man is able to pay and whether he should be committed to prison for non-payment. But we must here also distinguish between the man who conducts the case and the witnesses whom he calls. If nobody appears on behalf of the plaintiff except the debt-collector, whose function is merely to give evidence, would not the judge be justified in striking out the case on the ground that there was no appearance for the plaintiff?

What you say about a solicitor is correct enough, but the solicitor need not personally interview the debtor or write to him. He may employ a clerk for the purpose or even employ a debt-collector to do all the business except the conduct of the case in Court, and though his commission would be somewhat higher it would be worth paying, and I think solicitors would find it worth while to take up this class of business at a percentage.

But I do not think a doctor would gain much by trying to collect his debts by imprisonment—the favourite remedy, it would seem, of debt-collectors. If there were two doctors in the same locality one of whom imprisoned his debtors while the other did not, the latter would soon obtain all the business of the poorer people. And imprisonment for debt has now attained such dimensions and has created such an outcry that its days seem numbered. Certainly the public will not support any measure for making imprisonment cheaper and more expeditious than at present.

I am, Sir, yours truly,

B. L.

LAW FOR DRUGGISTS AND LAW FOR QUACKS.

To the Editor of The Medical Press and Circular.

Sir,—At the Mansion House on Friday last a firm of chemists was fined 40s. and 20s. costs for dispensing a prescription deficient in cinchona alkaloids to the extent of 55 per cent. of the amount that should have been present. The Magistrate wisely observed that it was a serious case because it was important to protect the public when they had prescriptions to be made up. In this case, the firm being one of repute, it is probable that the deficiency occurred owing to a mistake, and of this they, pleading guilty, accepted the responsibility. If the law has been made sufficient to reach comparatively trivial offences of this kind is it too much to ask that it should be extended to include the systematic and cruel frauds which are now allowed to be carried on with impunity by proprietors of quack medicines? Deducting the value of the small percentage of legitimate preparations paying stamp duty from the gross sum expended annually on "patent" medicines there remains a total of not less than £2,500,000 out of which the people are annually fleeced by vendors of quack nostrums. If this plunder represented merely pocket-picking it ought not to be allowed, much less ought such a trade be tolerated when associated with the infliction of suffering, injury and death. In previous communications I have explained and illustrated the cruelty of this form of quackery. My enquiries into the question continue, and they strengthen my opinion that the educated public and the legislature would not long tolerate the present abuses if once fully exposed. During the past few weeks, as visiting member of a hospital committee, I have given attention to cases of gastric ulcer. These have been patients of the domestic servant and dressmaker class. In a large proportion of instances I have found that these poor girls, often for prolonged periods before applying for medical advice have been relying upon one or other of the advertised cures for dyspepsia and stomach troubles; and have thus passed into a serious or dangerous condition (I have seen one fatal case of perforation within the past few weeks) which proper treatment might easily have averted. The bogus medical remedy trade is not only fraudulent, it is murderous; and this could be easily proved before the Royal Commission, which, let us hope, may be demanded and granted within the next few years.

I am, sir, yours truly,

Henry Sewill.

Cavendish Square, August 10th, 1907.

MILK AND TUBERCULOSIS.

To the Editor of the Medical Press and Circular.

Sir,—In view of the fact that Dr. Granville Bantock's opinions put forth during a discussion under the above heading in April last, must have influenced many of your readers and perhaps made some of them sceptical as to the necessity of the precautions against tuberculous infection insisted upon by the great majority of scientific sanitarians, it would be most interesting if Dr. Bantock would tell us whether he has read Dr. H. E. Armstrong's paper, published in the Medical Press of to-day (August 7th), and, if having read it, he adheres to the opinions he held four months ago. The tremendous practical importance of the issues involved seems to me to make it almost obligatory upon Dr. Bantock to justify his position, or to confess that it can no longer be maintained.

I am, Sir, yours truly,

A Family Doctor.

August 7th, 1907.

SPECIAL ARTICLE.

ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

Exeter, July 27th to August 3rd, 1907.

[From our Special Correspondent].

(*Conclusion.*)

The seventy-fifth Annual Meeting has come and gone and by one and all has been voted a great success. Scientific discourses, social functions, and renewals of friendships have each played a part; and if we mistake not the tastes and wishes of every type of visitor must have been thoroughly met. And now all that remains are pleasant memories and a plethora of papers which we imagine will more than meet the requirements of our contemporary, the *British Medical Journal*, during what even in the medical profession must be considered "the slack season."

Recollections and Reflections.

Our retrospect fills us with a general sense of satisfaction. The more successful a meeting is, however the more anxious should we be that its benefit and influence may be widespread and permanent. As compared with the conferences held by many other scientific and technical bodies, it must be admitted that the chief annual meeting of British medicos would not strike the onlooker as being what is most comprehensively described as "serious." There are many who deplore, and rightly so, the apparent lack of real interest in the consideration and discussion of those scientific principles and facts which should afford a sure and rational basis for the practice of the healing art. There certainly seems to be a danger that while the British Medical Association is undoubtedly attracting to its annual gatherings those who are keenly interested in what may, without discredit, be termed its "trade union" matters, those caring little for medico-ethical and medico-political discussions, but deeply concerned with scientific research and pathological progress, are quietly dropping their adherence and silently ceasing to take their part. Certainly in the recent meeting some of the best-known scientists and experts in medical science in this country were conspicuous by their absence. If this lapse of the scientific side of the annual meeting is to be allowed to continue, medical science will suffer incalculable loss. It is clear that there is need for special encouragement and thorough organisation. The work of the Sections requires to be arranged with greater care. Discussions should be planned with discrimination, and those specially qualified to take a useful part should be individually invited. Papers should be printed in advance. A Manual of Abstracts of all papers to be presented should be available a week before the meeting commences. It should be permissible for an author to arrange for the publication of his paper whenever he thinks fit. And perhaps most important of all, the scientific work should be collected and published in a special single number of the Association's *Journal* immediately after the meeting. These are not impossible suggestions, and if carried out they would go far to increase the real scientific value and general instructiveness of the meeting, without impairing its social enjoyments or robbing it of its justifiable picnicking.

THE PATHOLOGICAL COLLECTION.

Undoubtedly the most valuable feature of the Exeter Meeting was the very admirable Pathological Museum. Last week we were only able to refer to some few of the exhibits. Where every specimen presented points of interest it is extremely difficult to particularise. The catalogue provided was excellent, but it needed an index and lacked a conveniently arranged list of exhibitors.

A particularly helpful section was that portraying morbid affections of the skin. Mr. Jonathan Hutchinson sent a series of photographs and water-colour drawings illustrating various forms of cutaneous disease. Dr. David Walsh exhibited some particularly interesting photographs showing a frontal band area devoid of long hair or sparsely-haired or pencilled with a thin rim of hair, on one or both sides of the forehead, in cases of enlarged thyroid, and patients with potential Graves' disease and other somewhat allied affections. He also showed interesting water-colour drawings and photographs of generalised condylomata following primary infection of the left side of the upper lip.

Other valuable skin exhibits were made by Dr. P. S. Abrahams, Dr. B. H. Spilsbury, and the London School of Clinical Medicine. Dr. A. Moritz and Mr. P. B. Tubbs furnished a beautiful series of colour photographs of syphilitic and other lesions, taken by the Sanger-Shepherd process.

A feature of particular interest to teachers of morbid anatomy was Mr. G. Lenthal Cheatle's collection of giant sections, invaluable for the instruction of the student. Dr. William Hunter showed a number of specimens illustrating the hæmolytic, glossitic, gastric, and intestinal infective lesions of pernicious anæmia, which proved a valuable supplement to the discussion on this subject held in the section devoted to pathology.

It is quite impossible to mention anything like all the exhibitors, but we may note that preparations of particular interest were shown by Professor Walker Hall, Dr. F. W. Mott, Professor Symmers, Dr. J. Mitchell Clarke, Dr. T. Grainger Stewart, Dr. C. H. Miller, Professor G. A. Wright, Mr. B. G. A. Moynihan, and Mr. J. Bland-Sutton.

Many X-ray photographs of considerable clinical interest were exhibited by Dr. Reginald Morton, Mr. Rutherford Morison, Dr. J. Delpratt Harris, Dr. W. Cheyne Wilson, and Mr. E. W. H. Shenton. It should also be added that many specimens had been lent by the Royal Devon and Exeter Hospital; the Faculty of Medicine, University College, Bristol; the Royal Dental Hospital; the London School of Clinical Medicine, and other public bodies.

We have at least shown that the collection was a thoroughly representative one. Its usefulness would have been immeasurably increased if arrangements had been made whereby the various exhibitors could have demonstrated their particular specimens at set times. It is to be hoped that those responsible for the Museum at next year's meeting at Sheffield will make special arrangements for lantern and other desirable forms of practical demonstration of the more important specimens, instruments and photographs exhibited in the Pathological Museum.

We would suggest that those arranging for the collection at Sheffield would do well to endeavour to provide specimens and photographs of those particular deformities and diseases which directly or indirectly are connected with or in any way dependent on the very special forms of employment followed by such large numbers of the population in that great centre of industry.

GATHERINGS: OFFICIAL AND NON-OFFICIAL.

The Association's Annual Meeting furnishes opportunity for numerous and varied gatherings, some scientific, many social, both official and non-official. A broad-minded spirit of tolerance, sympathy and co-operation prevails, and such is to the general good.

On August 1st the Science and Education Committee of the National Temperance League held its annual breakfast, when some 160 members attended. The Mayor of Exeter (Mr. W. H. Reed) presided, and the president (Dr. Henry Davy), the Sheriff of Exeter (Dr. Ransom Pickard), the ex-president (Dr. R. A. Reeve, of Toronto), Sir John Moore, Mr. McAdam Eccles, Dr. A. T. Schofield, Dr. William Odell, Dr. T. N. Kelynack, Dr. Basil Price, and Mr. J. T. Rae (secretary of the National League) took part in the proceedings.

The same evening the Annual Dinner of the Association was held under the presidency of Dr. Henry Davy, when many toasts were enthusiastically honoured, and numerous eloquent speeches delivered.

Also on August 1st the Continental Anglo-American Medical Society held its annual luncheon, Professor W. Osler being in the chair, with a representative gathering of members and guests, including Dr. T. McCrae, of Baltimore, Dr. F. M. Sandwith, Dr. Newton Pitt, Dr. Ward Cousins, Dr. Galabin, Dr. Watson Williams, Dr. T. N. Kelynack, Dr. Herbert Tilley, Dr. Cholmeley, and many others.

The Irish Medical Schools' and Graduates' Association also gave a luncheon, and held their annual summer meeting.

Numerous garden parties, receptions, private luncheons, short tours, excursions, golfing and other pleasurable pursuits were crowded into Exeter's record week.

Among the many who have earned the sincere thanks of the Association and all its members, reference must be made to the genial and indefatigable President, Dr. Henry Davy, the alert and painstaking Hon. local secretaries, Mr. Russell Coombe, Dr. Clapp and Mr. Leonard Tosswill, and their numerous colleagues and helpers, the organisers of the Pathological Museum, Drs. Solly and Hawker. Indeed, to all our professional brethren in and about Exeter, and to the civic authorities and citizens generally, we offer on behalf of those who have enjoyed West Country hospitality, a very warm expression of appreciation and thanks.

THE ANNUAL EXHIBITION.

OWING to the necessarily condensed review of the recent Exhibition at Exeter, we were unable to deal as we could wish with certain preparations of particular interest to medical practitioners. Prominent amongst these the Nestlé's Anglo-Swiss Condensed Milk Co., Ltd., showed specimens of their Infants' Food, now well-known under the name of "Milo." This food has been produced in accordance with the strict physiological requirements of infant life.

A new Non-Irritant local anæsthetic "Novocain" was shown by the Saccharin Corporation, Ltd., of 165 Queen Victoria Street, E.C. This agent is being extensively employed for infiltration anæsthesia as it is much less toxic than Cocaine and can be used in conjunction with Adrenal products and is most effectual for lumbar anæsthetics, and in Ophthalmic, Dental and Naso-Laryngological work.

REVIEWS OF BOOKS.

THE MIND AND THE NERVOUS SYSTEM. (*a*)

This volume adds still another to the valuable series of works on general topics that have been given us by the well-known Zurich psychiatrist. As might have been expected, it is written in an interesting style and from a broad standpoint. It aims at presenting the rules of mental hygiene that should guide both the individual and society, and, as the author holds that for a full comprehension of the *rationale* of these rules, a fair knowledge of the mind and nervous system is essential, he has devoted two-thirds of the book to expounding the elements of normal and pathological psychology and physiology. The first section on psychology is written in a popular way that should increase its value to those medical men—unfortunately only too numerous in this country—who have had no training in this subject. The hygienic admonitions are sound throughout and largely follow the lines laid down in the author's larger work, "Die Sexuelle Frage."

ADAMS ON INFLAMMATION. (*b*)

We presume that many of our readers are already perfectly familiar with this monograph, which is in reality an extension of the article on Inflammation in Allbutt's well-known *System of Medicine*. It is, however, more complete and up-to-date. A fuller descriptive account of Wright's Opsonic theory is given. Likewise Bier's treatment of inflammation by induced hyperæmia has received attention. As regards the definition of the term inflammation, Adams leans to that put forward by Grawitz, who maintains that inflammation is the reaction of irritated and damaged tissues which still retain vitality. The manifestations of this process, under favourable conditions, are redness, swelling, heat and pain, to which Adams adds a fifth, viz., disturbance of function. Under unfavourable conditions all or nearly all of these symptoms may seem wanting, yet a minute examination of the tissues will show the same succession of changes.

The comparative pathology of inflammation is treated in an interesting manner, and a summary of the results so far reached at present is given. In the second part of this monograph the part played by the leucocytes in this process is very fully and clearly set forth. The chapters in this part of the book, describing the varieties and classification of the leucocytes, their functions and properties, and the theory of phagocytosis, are certainly, to our mind, the most valuable of all, and will be read with great advantage by every medical man who wishes to have a clearer conception of these matters. The author's remarks on the nature of the inflammatory exudation and the part played by the blood vessels and the nervous system in the process are clear and precise.

A very suggestive and helpful chapter is that dealing with the principles of treatment. The author shrewdly remarks that inflammation is a danger signal, but by no means necessarily a danger. He concludes by expressing his belief that it is by the study of cellular pathology in its strictest sense that the surest advance has been and is to be made in our knowledge of this the dominating process in disease. Professor Adams has been well advised in issuing in separate form this contribution to the modern pathology of inflammation. His observations shed a vast amount of light upon a somewhat obscure subject.

MEDICAL NEWS IN BRIEF.

Second International Congress of School Hygiene.

At the University of London Buildings on Monday, August 5th, at 3 p.m., the Earl of Crewe, Lord President of the Council, formally opened the Second International Congress of School Hygiene. On the previous Saturday an informal reception of the delegates had taken place at the University, and also two invitation receptions in the afternoon and evening respectively by Lady Londonderry, at Londonderry House, and by the Mayor of Westminster, at Caxton Hall. The Congress was very well attended, remarkably so when it is considered that a fortnight previously all the foreign invitations were in a state of chaos owing to the formalities that the Government offices insisted on with a determination worthy of a better cause. Most of the large and many of the smaller continental countries were represented, together with many of the Colonies and the United States, and a host of municipalities, large and small, in Great Britain. It may be taken as an indication of the world-wide interest exhibited in the Congress that even Siam thought well to appoint a representative. Lord Crewe, after conveying a special message from the King and a formal welcome from the Government, proceeded to deliver one of those happy speeches of which he is a past master and in which he threatens to rival his brilliant father-in-law. Lord Crewe had made himself well aware of the objects of the Congress and the methods by which those objects were to be pursued, and, speaking with ease and freedom, he created an excellent impression. No one who heard him was surprised that he had been chosen as the Government spokesman, though the absence of Mr. MacKenna, as Minister of Education, was much regretted. After Lord Crewe's speech, Lord Londonderry said a few agreeable words to show that the interest in the question in political circles is not confined to our side. Sir Lauder Brunton then delivered his presidential address. He, too, welcomed the delegates on behalf of the Executive of the Congress, and told them how much of the success of the undertaking was due to the personal influence and interest of that excellent diplomatist, the King. In an address, that was directed as much to the public as to the audience before him—for the great object of the Congress is to awaken general interest in the subject of School Hygiene—it was difficult for Sir Lauder to give those evidences of the originality of his genius which he has displayed in so many other fields, but his was a sound common-sense speech, and one eminently calculated to impress people with the idea that the question at issue is a practical one, and not an exotic off-shoot of the imagination or the silly creed of whimsical fanatics. After his speech, votes of thanks to himself and Lord Crewe having been passed with acclamation, a telegram was sent to the King expressing the thanks of the Congress for his interest. A conversazione was held in the University buildings in the evening, and on Tuesday the sections got to work. They met every day for papers, and such discussion as time permitted on the papers from 10 a.m. till 2 p.m., but their work was somewhat interfered with by the holding of a general discussion each day at noon on some set subject. On Tuesday this discussion centred on the methods of the first and subsequent medical examinations of school children; on Wednesday it concerned the lighting and ventilation of classrooms; on Thurs-

day, the school and its relation to tuberculosis, and on Friday, the last working day, on school-work in its relation to the duration of lessons, the sequence of subjects, at this season of the year. In the evenings, before and after dinner, there were lectures by eminent men on school subjects, and a number of excursions and visits to places of interest were organised by various committees and individuals. We hope to publish abstracts of some of the more interesting and important papers in the course of the next few weeks.

EXHIBITION OF BUILDINGS AND APPLIANCES.

Although the International Congress on School Hygiene has concluded its sittings, the exhibition of school building and furnishing appliances organised by the Royal Sanitary Institute will remain open at London University, South Kensington, until to-day. Taken collectively the exhibits brought together at South Kensington appear to present many essentials, from a hygienic point of view, for the equipment of elementary schools. International in its character, the exhibition shows in tangible form the movement for improving the hygienic conditions of schools now going on in so many countries. The features of the various systems favoured by countries other than our own in many cases are presented to the visitor by means of illustrations merely. In part, however, the exhibition consists of practical examples of school building and furnishing appliances. All departments of school hygiene are represented, ranging from building materials, floor and wall surfaces, water supply, drainage, sanitary appliances, warming, lighting, and ventilating, to the details of equipment, furnishing, teaching and technical appliances, gymnastic apparatus, and the accessories of the playground. To the appliances attempting to solve the problem of securing efficient ventilation without draughts one will naturally turn between much of the restlessness and inattention of which teachers complain arises from the enervating effects of stuffy classrooms. There is much in the exhibition to encourage hope of the problem, as applied to the schoolroom, being successfully solved. Improved types of desks, facilities for drying children's coats, shoes, and other apparel, and many more well-considered devices are shown for minimising the discomforts of school life and keeping children in health. In the grounds forms have been erected, among other structures, a handsome portable school pavilion of German make and design which, with the model and photographs of the Charlottenburg Forest School, presents many features that may profitably be studied.

Cholera Nostras in St. Petersburg.

ON August 9th there was a suspicious case of death at St. Petersburg. A *post mortem* examination has revealed the fact that death was due to cholera nostras. Telegrams from Samara, however, state that further fatal cases of cholera Asiatica have occurred there.

Status Lymphaticus Again.

AT Islington Coroner's Court on August 3rd, Mr. Schroder held an inquest on the body of William Percy Bishop, æt. 17, an indoor servant at Kensington, who died at the Great Northern Hospital. Bishop had a swelling in the upper part of the nose and went to the hospital to be operated upon. Dr. A. C. Brown, senior house surgeon, said that the operation took place, Dr. Rubra being the anæsthetist and Dr. Gay French, of St. Mary's the surgeon. The first incision had just been made in the nose when Bishop became white, and both operation and anæsthetic were stopped, but he died about two minutes later in spite of the efforts to revive him. The witness made a *post mortem* in the presence of Dr. Willcox, of St. Mary's, the Home Office expert. The *post mortem* revealed an enlarged thymus gland, a most unusual thing for a lad of 17. There was also an adenoid growth in the nose. Death was due to syncope caused by his condition from status lymphaticus. This condition could not possibly be diagnosed and could only be found in the present condition of medical knowledge after death. Dr. Rubra said he gave less than two drachms of chloroform and ether. The disease was receiving very careful medical attention at the present time. He had administered anæsthetic in over 10,000 cases. Dr. Brown, recalled, said status lymphaticus meant that certain glands secreted some fluids which acted as a poison, and evidence of this was found in several organs. There had been a very similar case some time ago in the West-end, that of a young baronet. A verdict of "death by misadventure" was returned.

An Unfortunate Accident.

AN inquest was held in Sheffield on August 12th on Mrs. Elizabeth Carlisle, the widow of a Sheffield ivory cutter, whose death was due to carbolic acid poisoning. The deceased's doctor, it was said, had several times taken to the house a small quantity of carbolic acid for use as a disinfectant. One morning, being in a hurry, he did not prepare the solution, but left the acid behind for Mrs. Carlisle's sister to mix later. Before she did so, however, the servant gave Mrs. Carlisle her medicine and inadvertently added a teaspoonful of the poison. A verdict of "Accidental death" was returned.

General Midwives' Board.

DURING the August sittings of the Examiners one hundred and thirty-one candidates were successful. Of these, the largest number were trained at the Maternity Charity, Plaistow; the General Lying-in Hospital, Queen Charlotte's Hospital, and the Salvation Army Maternity Hospital were also large contributors. Other candidates had undergone training at the Rotunda, Dublin, the Edinburgh Royal Maternity Hospital, Brighton Hospital for Women, etc., whilst a considerable number had attended the classes of Dr. St. Aubyn-Farrer and Dr. A. B. Calder.

The Alltymynydd Sanatorium.

A MEETING of the executive of the West Wales branch of the National Society for the Prevention of Consumption was held at the Carmarthen Guildhall on August 2nd, Mr. E. Trubshaw, of Llanelly, presiding. Dr. Douglas Reid, of Tenby, referring to the main object of the meeting—the consideration of the steps which should be taken to provide funds for the sanatorium at Alltymynydd, near Llanybyther—suggested that, in order to maintain the 20 beds there, the counties of Carmarthen, Cardigan, and Pembroke, should be divided into 20 districts, each of which should be responsible for a bed. He presented two alternatives, that there should be eight or ten districts in Carmarthenshire, six or five in Cardiganshire, and six or five in Pembrokeshire. The yields of the counties in the above order, if each person gave a penny a year, would be £67 10s., or £54 10s. per annum, with a population of 130,000, £43 or £52 with a population of 62,000, and £62 10s. or £75 with a population of 90,000. If possible, patients should pay a small weekly sum. In the event of fewer districts for each county, a few beds could be kept for the paying patients. A district which did not collect the sum required should not have the nomination to a bed. After a discussion, the executive decided to issue circulars to all likely subscribers in the West Wales counties.

University of London—The Rogers Prize.

UNDER the will of the late Dr. Nathaniel Rogers, the Senate offer a prize of £100, open for competition to all members of the medical profession in the United Kingdom, for the best essay or dissertation setting forth the results of original investigations made by the candidate on any medical pathological subject during the preceding two years. Candidates will be permitted to present papers published during the preceding year as the dissertation. The essay or dissertation, by preference typewritten or printed, must be sent in not later than May 1st, 1908, addressed to the Clerk of Committees, University of London, South Kensington.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT MEDICAL LITERATURE.

Treatment of Syphilis by Intramuscular Injections of Mercury.—Lambkin (*R.A.M.C. Journ.*, July, 1907) suggests a new preparation for use in this method of treatment. Hitherto the difficulty has been to find a vehicle which would remain aseptic, and at the same time be soluble in the organism. Glycerine, gumwater, olive oil, vaseline, oil of vaseline, and lanoline have all been used to hold the mercury in suspension, but each and all of them are open to considerable objections. For the past eighteen months Lambkin has been using palmatin as a vehicle. This is a neutral fat derived from palm oil, and having the same chemical composition as the palmatin of the human body. The advantages claimed for it are that it is non-toxic and non-irritant; it is as easily oxidised as the other compounds of human fat; being a normal constituent of the human organism it is easily saponified and soluble therein, and does not enter the circulation as a foreign body; as a vehicle it makes a more homogeneous preparation for injection than any other, and its melting point can be raised and lowered with the greatest facility. In order to obviate the pain which is a serious objection to the injections, especially when calomel is used, Lambkin suggests the use of a combination of pure creosote and camphor. The formulæ of the two mercurial creams which Lambkin is now using are as follows:—Hydrargyrum pur., 10 grammes; creo-camph., 20 cc.; palmatin basis to 100 cc.; 10 m. equals metallic mercury one grain. Calomel, 5 grammes; creo-camph, 20 cc.; palmatin basis to 100 cc. 10 m. equals one half grain of calomel. Each cream has a melting point of 37°C. The creo-camph. consists of equal parts of absolute creosote and camphoric acid. Each of the creams can now be obtained from Messrs. Oppenheimer in aseptules graduated to hold a maximum dose of 15 m.

K.

Acute Dilatation of the Stomach.—Telford (*The Med. Chronicle*, July, 1907) records a case of this rare condition which ended fatally in three days. The patient, a boy, æt. 16 years, was suddenly seized with severe colicky pains in the upper part of the abdomen. These pains persisted for about thirty-six hours, when he began to vomit large quantities of reddish yellow fluid. The vomiting persisted, and there was no motion of the bowels, although some medicine had been taken. The boy left his bed with the intention of going to stool, and on his return was found to be in a very collapsed state, and died in a very few minutes. The patient had not been seen by a medical man before his death. At the *post-mortem* examination the stomach was found to be very considerably distended, and contained six pints of fluid of a similar nature to that which was vomited before death. The stomach walls were deeply congested, and on them there were many submucous hæmorrhages. The first and second parts of the duodenum were involved in the distension, and the pyloric ring was scarcely perceptible. The remaining part of the intestines were collapsed and empty. The distension of the duodenum ceased abruptly at the point where the gut is crossed by the mesenteric vessels, but Telford was unable to assure himself that the gut had been constricted by these vessels. It was ascertained that the boy had had six similar attacks at various intervals during the three days which preceded his death.

K.

The Influence of Heredity in the Prognosis of Phthisis.—Von Ruck (*Amer. Journ. Med. Sciences*, August, 1907) investigates the commonly received opinion of the unfavourable influence of tuberculous ancestors on the prognosis in cases of phthisis. It has recently been suggested that the old idea is not correct, and that the children of tuberculous ancestors enjoy a partial immunity from tuberculous infection; and even when infection does take place the prognosis is better than in those not so protected. Von Ruck gives the figures of Turban and Weicker in support of this hypothesis, as well as the records of the last 1,415 cases treated at the Winyah Sanatorium. Of these patients 31.11 per cent. showed a history of tuberculous ancestry. Of those discharged cured, and of those discharged improved, 32.16 and 31.5 per cent. respectively had an hereditary taint, while of those who failed to improve or got worse only 25.13 per cent. gave such a history. The numbers are not sufficiently large to warrant any dogmatic conclusions, but the indications point in favour of the view that the mere fact of a tuberculous family history need not, in any individual case, diminish the patient's chance of recovery.

K.

The Cause of Sea-Sickness.—Lund (*Practitioner*, August, 1907) investigates the cause of this condition, and comes to the conclusion that the stimulus which causes the vomiting reaches the brain through the auditory nerves. He does not believe that the organ of vision transmits the impulse as blind people are found to suffer from sea-sickness to a greater extent than those who can see. Thus sixty per cent. of the pupils of the Liverpool School for the Blind suffer from the complaint, and another twenty per cent. are uncomfortable when taking a sea trip from Liverpool if the sea is at all rough. He has found, however, that deaf mutes never suffer from sea-sickness, nor do they experience that sensation in the stomach once described as a momentary displacement of the viscera to which most of us are liable when descending in a lift. Lund concludes that there is some mechanism in the auditory organ, possibly the system of semicircular canals, which is directly affected by the oscillations of a vessel at sea, and which acts as a stimulus to the vomiting centre. It is conceivable that these sudden movements may create in the endolymph in the semicircular canals a condensation or rarefaction, or both alternately, thereby altering the pressure on the nerve endings and causing a direct stimulus to vomit.

K.

The Mongolian Pigment Spots.—Brennemann (*Archives of Pediatrics*, June, 1907) deals with the occurrence of these spots in the infants of the American negroes. In the sacral or sacro-gluteal region of nearly all Mongolian children are found one or more well-defined distinctly blue or greyish-blue spots varying in size from that of a small coin to that of an expanded hand. These spots may be found in 97 to 98 per cent. of such children up to two and a half years of age, and in 10 to 12 per cent. after four years, and only rarely after the fifth year. For some time the condition was looked on as a racial characteristic of the Mongolian, but Adachi has shown that it it also occurs, though more rarely in the children of other races. Brennemann has examined forty coloured children under one year of age, and has found the spots well marked in thirty-five of them. In older children it is impossible in the majority of cases to decide whether a spot is still present or not; but in the younger children there is no such difficulty Brennemann is inclined to look on this pigmentation. as a persistence in a rudimentary form of what was once a more wide-spread and functional layer of pigment such as exists in certain monkeys; but why the remnant should favour the sacral and adjoining regions when there is no such tendency in monkeys, he is unable to explain. It is, however, obvious that we can no longer consider these spots as exclusive race characteristics. K.

Kuhn's Lung Suction Mask for Hyperæmia Treatment of the Lungs.—Kuhn's (*Mun. Med. Woch.*, 1907) mask consists of a celluloid cap to cover mouth and nose, which renders inspiration difficult, while expiration proceeds unhindered. This induces hyperæmia in the air passages and lungs. Kuhn's experience at Von Leyden's clinic has been decidedly favourable, and Stolzenburg also reports great benefit from the use of the mask in 24 cases of pulmonary tuberculosis. It not only relieves the patients subjectively, but exerts a favourable influence on the morbid process. He adds that it is perfectly harmless. Kuhn found in 16 patients that the number of reds increased by a million after one hour's use of the mask, while the whites increased by one thousand. He has used the mask further in five cases of fibrinous pneumonia and the disease assumed a very mild course. In a case of severe asthma, the patient, a woman, has been free from attacks for the first time for years since she has been systematically using the mask. D.

Acid Intoxication, a Factor in Disease.—Talbot (*Med. Record*, June, 1907), in investigating the cause of erosion of the teeth, has collected tests of the total acidity of the urine of a large number of patients. He believes that excessive acidity of the urine is associated with interstitial gingivitis and is an indication of faulty metabolism. D.

The Diagnosis of Pyelonephritis Based on the Abnormal Retention and the Delayed Excretion of Methylene Blue.—Beer (*Journal of the American Med. Assoc.*, June 8th, 1907), in a preliminary communication, publishes the histories of two cases which seem to point to a new diagnostic sign of the involvement in suppuration of the kidney parenchyma. In the first case, the patient discharged methylene blue stained pus in the urine at intervals up to two and three-fourth years after the last administration of the drug. The second patient had pyelonephritis (verified by nephrotomy) and recurrent discharges of methylene blue stained pus over a month after the last administration of the drug. He produced pyelonephritis in a dog and then for several days administered methylene blue. The kidney was removed two days later, and after treatment with oxidizing agents, showed multiple bluish-grey foci throughout its substance. He summarises his conclusions derived from the facts so far as follows: (1) There is no differential diagnostic sign between simple pyelitis and pyelonephritis. (2) Pyuria from the upper urinary tract may be due to either of these conditions. (3) By use of the above described methylene blue test it would seem that a differential diagnosis may be made. (4) Methylene blue is deposited in the parenchymatous abscesses and may be stored in these for years. (5) A late discharge of methylene blue, bound to the pus, is indicative of the rupture of such parenchymatous abscesses into the pelvis of the kidney, and is consequently diagnostic of pyelonephritis. D.

The Examination of the Heart in the Trendelenburg Position.—The examination of the heart with the pelvis elevated possesses, according to Stern (*Mun. Med. Woch.*, 1907) the following advantages: (1) The percussion of the right border becomes easier; (2) doubtful systolic murmur at the apex becomes more evident or disappears; (3) the presystolic murmur in mitral regurgitation complicated with stenosis is more readily detected. D.

The Action of Atoxyl upon Syphilis.—Uhlenhuth, Hoffman, and Rorcher (*Deut. Med. Woch.*, 1907) report a series of eleven cases of syphilis treated by atoxyl and conclude that it has an unmistakable good effect when used in sufficiently large doses; it is especially beneficial in the malignant forms. They injected intramuscularly ten cases with a 10 per cent. solution, and one with a 15 per cent. solution. The injections were of .2 to .6 gm. every two days at first, later every three days. It caused no local disturbance. It makes a very important addition to our means of combating syphilis in those cases which have an idiosyncrasy against the mercury and iodide treatment. D.

New Investigation on the Dorsal Foot Reflex.—Lissman (*Mun. Med. Woch.*, 1907). The dorsal foot reflex consists in the movement of the toes on tapping the outer part of the dorsum of the foot with a percussion hammer. Normally the toes (excepting the great toe) are extended, but in disease plantar flexion may occur. Lissman confirms the observations of the two describers of the reflex, finding it positive (*i.e.*, plantar flexion) only in cases with positive Babinski's sign, and absent altogether in anterior poliomyelitis. He also found in infancy the reflex positive in all cases with positive Babinski. The significance of this sign is therefore identical with that of Babinski's, indicating (except in infants) disturbance of conduction in the pyramidal tract. D.

Tuberculosis and Heredity.—With a view of testing the doctrine of the hereditary transmission of tuberculosis, Hagen (*Johns Hopkins Hospital Bulletin*, August, 1907) has examined the condition of certain families, of each of which two or more members were attending the Phipps Dispensary. In all 83 families were examined, containing a total of 534 individuals. Of these 254, or 47 per cent. were tuberculous, and 13 were suspicious. In 62 per cent. of the tuberculous cases there was no tuberculosis in the immediate ancestors, 43 per cent. of those exposed to marital infection became infected, while only 38 per cent. of those exposed to parental infection developed the disease. Only three persons of tuberculous stock developed the disease when not in association with their families. There were eleven well marked instances of house infection. In fifteen instances one or both parents had the disease, while the children were entirely well. Hagen's conclusions, therefore, are entirely opposed to the doctrine of hereditary transmission. Moreover, as his families were selected definitely on account of the large number of infections occurring in each, one would expect in them, if anywhere, to find evidence in favour of hereditary influence. On the other hand, he believes that "infection acquired by long continued and intimate association plays the only *role* in the transmission of pulmonary tuberculosis." R.

Manchester University.

At the Graduation ceremony last week the following were recipients of degrees:—

Degree of Master of Science.—Harry Andrew, George Henry Kenyon, Frederick William Dyson Marshall, and Charles Watson Moore.

Degree of Master of Surgery.—Arthur Ralph Thompson.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Thomas Wingate Todd, first-class honours; John Arnold Fairer, second-class honours; Frank Hartley, second-class honours; Robert Lakin, second-class honours; John Webster Pride, George William Bury, Harold Coppock, Daniel Irving Dakeyne, James Fleming Dow, Frederick Hall, Vasantrio Dinanath Madgavkar, Peter Moran, Wilfrid Nightingale, Alice Oberdorfer, George Rainford, Robert Robertson, Douglas Rodger, Elsie Marsh Royle, Vincent Southwell, Gilbert Bertram Warburton, Henry Whitehead, and Norman Reginald Williamson.

NOTICES TO CORRESPONDENTS, &c.

☛ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessary for publication but as evidence of identity.

ESPERANTO.—The address of the Esperanto headquarters is Arundel Street, Strand, W.C. You had better apply to the Secretary, as he will probably be able to say whether any medical books are published in Esperanto. We do not know of any.

GYM.—The founder of the system known as "Swedish Gymnastics" was one Henrik Ling, a university fencing Master at Lund, Sweden. He founded the Central Gymnastic Institute, and published a large book on "General Principles of Gymnastics." Ling was born in 1776, and died 1834. He was succeeded and his methods developed by Gabriel Branting (1799-1881) and his own son, Hjalmar Ling (1820-1886).

THE GREAT PEPPERMINT CURE.

Readers who are unacquainted with the recondite properties of peppermint will be surprised to learn, from the following extract from the *Financial News*, the amount of commercial value they represent:—

"W. E. Woods Great Peppermint Cure Company.—July 30. £20,000 (£1). To adopt agreements (1) with the W. E. Woods Great Peppermint Cure Company, Limited (registered in New Zealand), and W. E. Woods; (2) with H. T. Tompsitt and S. Fripp; and (3) with Spottiswoode, Dixon and Hunting, Limited, to pay to the said New Zealand Company royalties on sales by this company of "Peppermint Cure," and to carry on the business of proprietors and manufacturers of and dealers in patent medicines, etc. No initial public issue. First directors (not less than three nor more than five): J. P. Humphris, W. E. Wood, and R. St. J. Hughes. The said New Zealand Company may, while holding £5,000 shares, appoint a permanent director, the said W. E. Wood being its first nominee. Qualification (except permanent director), 250 shares, £100 each per annum. 57 Moorgate Street, E.C."

H. N. T.—The routine administration of potassium iodide in cases where excess of mercury has been taken is not unattended with danger, as by releasing the metal from the tissues it passes into the circulation, and may considerably aggravate the symptoms.

ETHICAL.—We cannot undertake to recommend particular disinfectants, as such advice is out of our province, but you may take it that the advertisements of such as are admitted to the columns of reputable medical papers are all pretty efficient, and the makers will gladly supply you with literature concerning them.

Vacancies.

Bailbrook House, Bath.—Medical Superintendent. Salary, £450 per annum. with board for self and wife if married, furnished quarters, laundry, attendance. Applications to Herbert Coates, Secretary, 49 Broad Street, Bristol.

North Lonsdale Hospital, Barrow-in-Furness.—House Surgeon. Salary, £100 per annum. with board and lodging. Applications to the Secretary, North Lonsdale Hospital, Barrow-in-Furness.

Egyptian Government.—Kasr El Ainy Hospital.—Resident Medical Officer. Salary, £250 a year, with quarters, servants, washing, coal, and light. Applications to The Director-General, Public Health Department, Cairo.

Egyptian Government.—Ministry of Education.—School of Medicine, Cairo.—Assistant to the Professor of Pathology. Salary, £E.320 per annum. Applications to The Director, Government School of Medicine, Cairo, Egypt.

Royal South Hants and Southampton Hospital.—House Physician. Salary, £100 per annum, with rooms, board, and washing. Applications to T. A. Fisher Hall, Secretary.

Loughborough and District General Hospital and Dispensary.—Resident House Surgeon. Salary, £100 a year, with furnished rooms, attendance, board, and washing. Applications to Thos. J. Webb, Secretary.

Glasgow District Asylum, Woodilee, Lenzie.—Assistant Medical Officer. Salary, £135 per annum, with board, lodging, washing, etc. Applications to the Medical Superintendent.

Worcester County and City Asylum.—Assistant Medical Officer. Salary, £140 per annum. Applications to Superintendent Powick, Worcester.

Devon County Asylum.—Assistant Medical Officer. Salary, £140 per annum, with board, apartments, and laundry. Applications to the Medical Superintendent, Exminster.

Rochdale Infirmary.—House Surgeon. Salary, £100 per annum, with board, residence, and laundry. Applications to Henry Booth, Secretary, 58a Yorkshire Street, Rochdale.

The Royal Victoria Hospital, Dover.—House Surgeon. Salary, £100 a year, with board, lodging, and washing. Applications to the Hon. Secretary, Arthur B. Elwin, Esq., 2 Castle Street, Dover.

York County Hospital.—House Surgeon. Salary, £100 per annum, with board, residence, and washing. Applications to Fredk. Neden, Secretary and Manager.

County Asylum, Prestwich, Manchester.—Junior Assistant Medical Officer. Salary, £150 per annum, with board, furnished apartments, and washing. Applications to the Medical Superintendent.

Royal Albert Hospital, Devonport.—Resident Medical Officer. Salary, £100 per annum, with apartments, board, fuel and lights, and laundry. Applications to the Chairman of the Selection Committee at the Hospital.

County Borough of Northampton.—Medical Officer of Health. Salary, £400 per annum. Applications to Herbert Hankinson, Town Clerk, Guildhall, Northampton.

Appointments.

BENTHALL, ALBERT, F.R.C.P.Edin., M.R.C.S.Eng., under the Workmen's Compensation Act, 1906, a Medical Referee for Circuits Nos. 40 and 42.

BURTON, C. F., M.R.C.S.Eng., L.S.A., by the Shipping Federation, Examining Officer of Seamen at Whitby under the Compensation Act.

DAVIDSON, THOMAS, M.B.Edin., House Surgeon at the Stockton and Thornaby Hospital.

DE SOUZA, D. H., M.B., B.S., B.Sc.Lond., Demonstrator in Physiology at the University of Sheffield.

GOUGH, A., M.B., Ch.B.Leeds, House Surgeon at the General Infirmary, Leeds.

GREENWOOD, F. G., M.B.Cantab., House Physician at the General Infirmary, Leeds.

RODRIQUES, N. JOSEPH, L.R.C.P. and S.Edin., Assistant House and Visiting Surgeon to the Stockport Infirmary.

TINLEY, W. E. F., M.D.Durh., Certifying Surgeon under the Factory and Workshop Act in the Whitby District.

WALKER, M. G. L., M.B., Ch.B.Leeds, Junior Resident Ophthalmic Officer at the General Infirmary, Leeds.

Births.

COLTART.—On August 4th, at 714 Fulham Road, London, the wife of Guy H. Coltart, M.B.Lond., M.R.C.S., L.R.C.P., of twins (son and daughter).

COOPER.—On August 6th, at 87 Great Portland Street, the wife o A. Tanner Cooper, M.R.C.S., L.R.C.P., of a son.

Marriages.

MUNRO—MACLEOD.—On August 7th, at St. James's Church, Westend, Southampton, Ranald Martin Cunliffe Munro, B.A., Barrister-at-Law, of Queen Anne's Mansions, son of the late Major-General A. A. Munro, Bengal Staff Corps, of Woodside, Frant, to Norma, daughter of Colonel Kenneth MacLeod, M.D., LL.D., Indian Medical Service (retired), Honorary Physician to H.M. the King, and of Mrs. MacLeod, Duncaple, Westend.

PHILIP—KYD.—On August 8th, at Rosebank, Aberdeen, James Farquhar Philip, M.D., Ealing, son of the late Rev. William Marshall Philip, M.A., minister of Skene, to Isabella Caithness, daughter of Thomas Kyd, resident manager at Aberdeen of the Northern Assurance Company.

RAMSDEN-WOOD—WILKINSON.—On August 6th, at Cookshire Quebec, Norris, eldest son of W. E. Ramsden-Wood, M.D., of Waterside, Uplyme, Devon, to Eva Millicent only child of J Wilkinson. Esq., of Cookshire, Quebec.

Deaths.

BENNETT.—On August 8th, at Bimpert House, Shaftesbury, Elizabeth Louisa, widow of W. H. R. Bennett, M.R.C.S., L.R.C.P.

BUNTING.—On August 7th, at Earlham, Torquay, Agnes Selina (Chaplin). the wife of James Bunting, M.R.C.S.Eng.

KALLEY.—On August 8th, at Campo Verde. Edinburgh, Sarah Poulton Kalley, beloved wife of the late Robert Reid Kalley, M.D., Madeira and Brazil.

KENNARD.—On August 2nd, at Bloomfield House, South Lyncombe, Bath, Thomas Atherton Kennard, M.R.C.S., (late of Kempsey, Worcester), in his 74th year.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXV. WEDNESDAY, AUG. 21, 1907. No. 8

NOTES AND COMMENTS.

The Medical Referee Begins.

THE value of the medical referee under the Workmen's Compensation Act, 1906, was demonstrated signally before the end of the first month that the measure came into force, by an incident in the Birmingham County Court. A workman had been injured in the head at some bedstead works, and been paid compensation; but after some time the firm thought him fit to resume his duties. The medical man consulted by the workman's solicitor did not take the view of the firm's medical man, and the question was put by the court to the medical referee. This gentleman, after examination, certified that the workman's pain and giddiness were not attributable to the accident, but to his being out of work and indulging in excess of alcohol. Under these circumstances the judge naturally stopped the payments. Before the employment of referees such a case as this would have been fought out in Court, and besides the waste of time and money, it is just as likely as not that the judge would have given a wrong decision. The whole question in these cases turns on the medical aspect of the case, and no one but a medical man is able properly to judge of that. We venture to expect that if the medical referees are freely employed at first by the County Courts, the bogus claimant and the adventurous solicitor will find the Act is not such a soft thing for them as they anticipate. Under the old Acts, as is commonly known, malingering and fictitious injuries were commonplace scandals, which had only too much chance of encouragement if they went to court.

A Valuable Knee.

WITH a little observation and ingenuity it was quite possible for a sharp workman who preferred half wages and nothing to do to full work and full wages, to make a comfortable living out of some old injury. All that was necessary was to obtain employment, work for a week or two, and then have an "accident" to the old place. The employer was then bound to pay till he got tired. A notable story of an alleged professional claimant was told at West Ham Police Court the other day, when a man was charged with obtaining money by false pretences from a confectioner. It was said that this man had a very profitable knee, which every six months or so was served up in a claim for damages against some local tradesman for having a defective cellar-flap or pavement-light which tripped up the owner of the knee. A tobacconist gave evidence of parting with £33, a caterer £6 in cash, the doctor's fees, and £1 in goods, and a tailor £30 in about 18 months, all for the same knee and for similar accidents. All medical men know the difficulty of resisting a claim where there is a definite lesion involved, even though convinced that it has little or no relation to the accident. It may now reasonably be hoped that in workmen's compensation cases, at any rate, the medical referee will be able to put a stop to much misplaced ingenuity.

Hounslow and Out-patients.

THE dislike and distrust of the out-patient department is growing, if not on every hand, at least in many quarters, and the battles that are being fought against hospital abuse certainly centre round that institution as the worst offender. At Hounslow the medical men attached to the hospital appear to have taken the decided ground that the out-patient department is more abused than legitimately used, and consequently they have intimated that they propose to withdraw giving their services to it at the end of the year. The subscribers who are privileged to give away four out-patient letters in return for a guinea subscription wish to continue the department, and it will be interesting to see if any workable arrangement can be arrived at. There seems to be no doubt that the subscribers have been exceedingly indiscreet in the way they have given their letters away, and have thereby not only deprived medical men of their fees, but have by their action directly discouraged thrift. Dr. Gordon, of Hounslow, asserted in a recent interview that there is absolutely no need for an out-patient department, and that the medical men are determined that it shall cease, at any rate, as far as abuse is concerned. The subscriber who uses his hospital letter as a cheap form of patronage, and not as a public trust, is, alas! only too well known, and it is high time that he should be brought to realise his responsibilities.

Lord Curzon and the Plague.

AT the end of last month a letter written by Lord Curzon to one of those correspondents who ask such convenient questions of public men was published in a Chester paper and republished in the *Times*. In this letter the ex-Viceroy pilloried certain statements made by a Socialist orator that the British administration in India is responsible for the plague, and the Indian Government only exerted "puny efforts" to combat the scourge, as "grossly mendacious and ignorant." His Lordship asserts that the Government have conducted an "unrelenting campaign" for nine years, but that their efforts had been confronted throughout with appalling ignorance and superstition, and that the question often resolves itself into one, not of scientific method, but of administrative expediency. A very pertinent reply to this claim was made a few days subsequently in the columns of the *Times* by Dr. F. Fremantle, a late Plague Medical Officer in the Punjaub, who pointed out that though the Indian Government certainly undertook measures of some magnitude to combat plague in the early stages of the epidemic, they left undone the most important thing of all, namely, the scientific investigation of the cause of plague-spread. The Government have now got together some investigators—a small band—to try to work out this vital point, but it is obvious that this should have been the first step, and not the last. Public health measures are so absolutely dependent on exact scientific knowledge that it is often more than useless to carry out heroic campaigns against the most patent dangers, unless accurate information as to their remedy is previously obtained.

Judge Mulligan and Debt Collecting.

In our last issue we published a letter from a correspondent, "B. L.," on the subject of Judge Mulligan and debt collecting. Much of what he therein said is both true and to the point, and we would most heartily associate ourselves with him in his remarks about imprisonment. In theory, imprisonment for debt in the case of those able but not willing to pay is, of course, justifiable; in practice, it is one of the worst blots on our civilisation. Those who, like ourselves, have studied the question, must we believe hold the very idea in horror, so inequitably and so cruelly does the system operate in practice. The point which we would criticise in his letter, however, is where he speaks of the appearance of the debt collector in court. As our information goes, the debt collector is, to all intents and purposes, the principal in the matter—he proves the debt by means of producing a written acknowledgment of liability from the debtor. A County Court judge has discretion to hear whom he likes, but he can refuse to hear anyone except a party in person or his legal representative. Now, it has been found in petty debt collecting that by a simplification of machinery, sanctioned by custom, the small debtor gets off much more easily than by employing the full legal process, and the creditor is much more likely to come by his own. If abuse were shown we should be prepared to modify our views, but as we read the case his Honour is insisting on the pedantic employment of the full legal machinery, and thereby stultifying the ends of justice.

LEADING ARTICLES.

SOME INDUSTRIAL DANGERS.

The Annual Report of the Chief Inspector of Factories and Workshops, which was noticed in these columns some months since, contains a great deal of matter of medical and of medico-social interest. Now that the responsibility of the employer is fully recognised, the community is to a great extent relieved of the cost of supporting the sick and wounded of the industrial army. It is only by an efficient system of skilled inspection that the workmen will ensure a proper protection and employers will be able to reduce accident and trade diseases to a minimum. The Report of the Chief Inspector, Dr. Whitelegge, for the year 1906, bears testimony to the thoroughness with which an enormous mass of detailed information has been collected and dealt with. There were in all 255,189 works inspected, employing in factories 4,150,000 persons, in workshops 700,000 and in laundries 100,000. The Certifying Surgeons, for medical reasons, rejected no less than 3,257 children and young persons desirous of obtaining employment in factories, and 2,016 for non-medical reasons. These figures afford some idea of the scope of the operations of the Factory Department which has during the year added to its Registers no less than 31,240 factories and workshops. There were 632 cases of lead poisoning notified in the year under report, as against 592 in 1905, 1,058 in 1900, and 1,258 in 1899. In connection with claims under the Workmen's Compensation Act under the heading "encephalopathy," in the cases of plumbism it is interesting to note eleven cases of epilepsy and coma, three of mental derangement, and seven of optic neuritis. The striking observation occurs that in one factory the occurrence of seventeen cases within the last four years led to an examination of 87 of the workers, of whom six showed a trace of a blue line, nine were pale or anæmic, one had definite partial paralysis of the right wrist and one weakness of the fingers. Of sixteen cases in the printing trade eight occurred in compositors, three in stereotypers, two in machine operators, and one each in a type caster, a store room hand, and a general worker. The blue line on the gums, we are told, is rarely found among printers. In thirty cases lead poisoning was returned as the direct or indirect cause of death. There are some ten or eleven thousand persons engaged in the tobacco, cigar and cigarette industry, but out of that number careful enquiry revealed only two cases of nicotine poisoning, two of amblyopia, one of gastralgia, and one of smoker's heart. Clearly, then, it would be impossible to consider that particular industry as an unhealthy one. The laundry industry presents some interesting statistics. In the year 1901 91,086 persons were employed, of whom 50,547 were engaged in steam laundries. During the year 1906 there were 301 accidents reported to the certifying surgeons, as against 288 in 1902. Some interesting facts are recorded in the Report of the Electrical Inspector. There were eight fatal electrical accidents in factories, engineering works, and so on. Four of these occurred under the heading of faulty apparatus, and it is significantly noted that many burns of that class are due to the circuits being too heavily fused, thus allowing heavy currents to flow under short circuit conditions. In one instance a man took hold of a leaky lamp fitting which he was repairing and received 230 volts through his body to earth, whilst standing upon some iron plates. A youth, in a cellar, the floor of which was wet with pickling brine, took hold of the pedestal of a leaky electrical fan with one hand, while he turned on the switch with the other. He received a current of 200 volts, alternating supply, through his body to the ground. He was unable to drop the fan until the current was cut off, when he immediately dropped to the ground and shortly afterwards expired. In another case an electrician was fitting up a temporary light, when he took hold of some wires in a joint which he had neglected to "tape up", and receiving a shock to earth with 200 volts was killed. "He probably," remarks the Inspector, "held the popular but erroneous idea that with such a low pressure there is no danger." In another instance a youth was killed whilst trimming an arc lamp which he had lowered to within a few feet of the ground. The switch was faulty and although the lamp was extinguished, the circuit was broken at one pole only, one blade of the switch remaining in contact with the other pole. The lamp was, therefore, alive at 200 volts above earth, the system being 3-phase, 350 volts per phase. The unfortunate youth was unable to release his hold of the lamp until switched off by another person, when he fell to the ground. This Report is in many ways full of interest to the public in general and may be commended to the notice of medical men in particular, for they will find therein a vast amount of information likely to be of great professional value.

PUBLIC HEALTH IN INDIA.

It is high time that the enormous waste of human life in our great Indian Dependency should engage the serious attention of the British Legislature. The responsibilities of Empire do not end with the simple establishment of law and order under the influence of a mild military despotism. It is impossible to disregard the moral obligation that is attached to the dominant British race in maintaining a good standard of public health in India. There is no lack of fearless and well informed criticism upon the point. Major Ronald Ross, a clear-headed authority on all aspects of epidemic disease, has spoken out his mind repeatedly in a way that no governors of a civilised country can permanently disregard. In a recent communication he sums up the chief points of the indictment against the Indian Government for its attitude with regard to the plague. The facts he brings forward are as follows:—(1) Although the disease had been raging in Hong-kong for two years before it appeared in Bombay, the Indian Government did not make adequate preparations to exclude it, or to detect and combat it on its arrival in India; (2) when it arrived in 1906 it was allowed to remain undetected for months; (3) when it was detected at last it was met only with the vacillating counsels of the unprepared; (4) although great efforts to check it have undoubtedly been made since then, it is questionable whether they have always been organized in the best possible manner. From this it will be seen that Major Ross accuses the Indian Government of want of wisdom and of inertia rather than of actual indifference to the plague. The root of the matter, it is to be feared, is to be found in the lack of a proper public health organisation throughout India. Even in our military administration sundry matters are on a far from satisfactory footing, an assertion that can be readily proved by a study of the Indian Army Medical Reports. In dealing with the native populations of the East it is, of course, necessary to realise that one is confronted with the vices of ignorance, superstition, and suspicion, but that is no excuse for defective sanitary administration. Major Ross makes a palpable hit when he points out that India has not done so well as other countries in dealing with malaria during the last ten years, that is to say, during the administration of Lord Curzon, who, in sanitary matters, is one of the strongest supporters of the policy and the administration of the Indian Government, yet malaria causes more sickness than plague does, and it can be dealt with medically without injuring the susceptibilities of the natives. It is open to Lord Curzon to state what serious practical measures were taken by him during his administration of India to check the ravages of malaria. Vague generalisations are not a sufficient answer in reply to the categorical thrusts of so doughty a knight as Major Ronald Ross.

CURRENT TOPICS.

A Prescription for Childlessness.

The *Herald of Health* is a journal primarily devoted to the cult of the vegetarian. Incidentally, however, it deals with a wide range of subjects, but appears to be mainly of the "anti" type of faith. A page at the end is devoted to "Hygienic Answers to Correspondents," for non-urgent cases and for those unable to pay fees. The Editor declines to advise the use of Wallace's specifics, for information as to which readers are referred to that gentleman's work on "Physianthropy." We gather that the writer in question is an unqualified practitioner and we further infer that he has certain original views upon vaccination, as on the same page a book is advertised under the title of "The necessity of small pox as an eradicator of organic disease." The Editor, himself, deals with the case of a correspondent who has "strained a gland in the groin during a foot race which has since suppurated." To meet this medically unknown pathological condition he advises a hot sitz bath 20 minutes nightly, or hot compresses for one hour, and that the feet be kept in hot water half an hour each night: salad oil and rest during the day. The attitude of the man who regards suppurating glands in the groin as non-urgent is somewhat startling, whatever view may be taken of his treatment of the following case, headed, "Is my wife well enough to bear a child?" The applicant having benefited by previous advice in many troubles would like his domestic life to be blessed by offspring. In his answer the editor gives detailed directions for "three good, slowly eaten meals daily, two of them consisting of bread made on Wallace lines or got from the P.R. (?) bakery, and fresh ripe or stewed fruit. The third meal is to consist of two new laid eggs, a heaped teaspoonful of conservatively and thoroughly cooked pulse, three ounces of ground nut, or three or four ounces of home-made Wallace cheese. The foregoing are to be eked out with various vegetables. 15 or 16 hours are to be devoted daily to exercise, domestic duties, visiting, reading, and so on. As soon as that can be done happily without being more fatigued than will enable you to enjoy a good night's rest and awake refreshed in the morning, and maintain your health otherwise, then you may prepare your hearts for the introduction of a little one into your home." We fancy that plain food and plenty of exercise is a somewhat old fashioned prescription for sterility, apart from bread and food "on Wallace lines." By the way Wallace appears to be a baker who advertises extensively.

State Medical Attendance.

THE recent plea of Dr. Newsholme in support of the provision of medical attendance by the State deserves careful consideration. It may be that he is simply thinking ahead of the times, and that the proposal which seems so revolutionary to-day may become the established fact of a few generations hence. For when the matter is looked into a little more closely it is evident that the principle has been already adopted in various directions by a State that is not given to headlong advances. For instance, the Poor Law of the United Kingdom recognises the right of any pauper citizen to receive medical attention at the expense of the community. Further, for the protection of the citizen, both individually and collectively, the legislature has decreed that vaccination shall be available free of cost to everyone. The most striking instance, however, to be found is in the public infectious hospitals which are open freely to all classes and are a charge upon the community. An extension of such services to the general public would, therefore, simply involve the development of existing machinery. Were the medical profession to discontinue the vast amount of gratuitous services rendered to hospital patients and to private persons from whom no payment is to be expected, a huge additional charge would at once be thrust upon the Poor Law, whose work is to a great extent anticipated by the contributions of the public and the labour of medical men. Sooner or later the State will probably have to protect or help to support the general practitioners.

Medical Papers and the Lay Press.

ABOUT six months ago a spirited protest was made from several quarters against the practice of certain medical journals sending round to the lay press advance proofs of original communications made to their columns. The objection seems to have been so far successful that the particular journal most concerned has not since been quoted in the manner objected to; but of late original papers in other of our contemporaries have been freely and accurately reproduced in some daily papers, with the author's name so prominently displayed as to suggest that the editors have not been unaided in the process of selection. Now though certain medical addresses, such as the introductory lectures at the medical schools, the Harveian oration, and so on, are usually reported in the lay press, these addresses are generally given with an eye to the diffusion among the public of ascertained medical truths, or medical views on socio-medical subjects. They are not given to glorify the lecturer's clinical skill or professional acumen. In the case of the papers spoken of above, it appears to be different. The authors' work as related in the particular communications referred to represent simply their own views, which may or may not be sound. Such papers are published in medical journals so that the profession may have an opportunity of forming a judgment on them, and till such judgment has been passed it is obviously most undesirable that sensational abstracts from the original paper should be published with startling headlines in the lay journals. The names of authors whose papers so appear are not likely to smell the more sweetly in the nostrils of the profession, and in their own interests and that of the dignity of the profession they would do well to put a stop to this unhappy practice.

The Hospital Building Craze.

THE proceedings of the Metropolitan Hospital Sunday Fund do not always meet with our unqualified approval. Indeed, we have on various occasions criticised freely their policy, for instance in their neglect of small hospitals, and in their arbitrary and inconsistent methods in enforcing amalgamation schemes. With their recent condemnation of the building craze on the part of London medical charities, however, we find ourselves in perfect accord. There are said to be about a thousand unoccupied beds in London hospitals at the present moment, but in spite of that fact, quite a number of those institutions are moving heaven and earth to forward fresh building schemes. Sir Edmund Currie has taken the matter vigorously in hand, and it is to be hoped that his efforts will give pause to not a few of those unbusinesslike schemes. A standing monument of "how not to do it" is afforded by St. Mary's Hospital, Paddington, which has erected a gorgeous new building at vast expense, but is unable to do more than keep the beds in the old premises occupied. It would be much more to the benefit of the community to insist upon accommodation being provided in outlying districts, instead of permitting a few large central hospitals to divert huge sums to their own aggrandisement. It is to be hoped that the hospital funds will exact their influence in bringing the medical charities into some sort of system as regards their present reckless expenditure upon extensions, regardless of debt and of deficiences of income. At the same time, Sir Edmund Currie may be trusted to look well into the individual cases of the smaller hospitals before coming to any decision as to their claims to public support.

The New Public Health Act.

ALTHOUGH the Public Health Bill which has lately passed the Commons is mainly consolidating, yet there are various additions of some importance.

There is little doubt that the Bill, pretty much as it now stands, will pass into law. The eighteen clauses dealing with infectious diseases are specially interesting. Among them are powers given to the medical officer to examine school children, to require a list of scholars when one is suffering from infectious disease, provisions as to library books, power to require dairymen to furnish a list of sources of supply, dairymen to notify infectious diseases existing among their servants, power to local authority to pay expenses of persons in hospital, and to provide nursing attendance. If a dairyman is called upon to state the sources from which his milk is obtained, he will be rewarded with the modest sum of sixpence; and if he fail to comply with the requisition he will be subject to a fine of £5 and a daily penalty not exceeding £2. The provision as to furnishing the names and addresses of all scholars applies to all schools, and the sixpenny scale of payment to the head of the school is the same as for dairymen, but the fine for non-compliance is only £2, and there is no continuing penalty. The local authority may provide nurses for persons suffering from infectious disease who cannot be removed to hospital, and may pay such reasonable sums for the services of the nurses as they think fit. But the operation of this, as of all the other sections, depends upon the initiative of the local authority.

A Permanent International School Hygiene Council.

AN important development of the late Congress on School Hygiene is the formation of a permanent International Council on the same subject. This Council is to consist of the president of the past two congresses and the president of the next congress, together with nine other members yet to be elected, but of whom three are to be natives of this country, three of the country where the next congress will be held, and three members from other lands. The Council is not to meet for discussion in the ordinary way, but will deal with subjects that arise by correspondence, and will be empowered to make decisions on urgent matters. The questions that they will consider almost at once are how medical inspection of schools can best be carried out with the maximum of efficiency and the minimum of cost; how far the laws of health can best be imparted to the rising generation, so that they may learn how to take care of themselves and those dependent on them; what are the best systems of physical training for both sexes at various ages; and how the feeding of improperly-nourished children shall be carried out without developing pauperism and with due regard to those on whom the cost falls. No one will deny the value of such functions nor be disposed to withhold admiration from the gentlemen who are sufficiently courageous to undertake them, but it may seriously be doubted whether the questions the Council propose to themselves are what may be termed international. They seem to us to be more strictly national, and to raise issues that each country must work out for itself according to its own customs, habits, and means. Still there are many points of general interest, such as the setting up of normal standards of vision for children of various ages, and the prevention of epidemics by school agency, in which the experience and knowledge of experts in different countries will be of high value, and we wish the new body every success in its honourable self-imposed mission.

The L.G.B. and Medical Salaries.

IT is highly unfortunate when the profession is striving to raise the quality and prestige of its members that a department like the Local Government Board, which is so intimately connected with medical work, should do anything to belittle medical men or to lower their remuneration. An almost incomprehensible instance of such action is reported from Edmonton. The Board of Guardians for that district lately advertised for an assistant medical officer for the workhouse, requiring a "whole-time" man, and offering a salary of £180 a year, without extra allowance. As a matter of fact, only two replies were received, neither presumably suitable, for the Guardians decided to advertise again, offering a higher salary, to wit, £220. This salary was disallowed by the Local Government Board, who no doubt were fully informed of all the contingent circumstances. With every desire that proper economy should be observed in local administration, it strikes us as preposterous that the Guardians are forbidden to offer a salary which will attract a suitable candidate for the purpose of looking after the comfort and well-being of sick paupers, and still more so that the whole time of a medical man is a post not very attractive from the professional point of view, should be rated at not worth four guineas a week. The Local Government Board must surely be aware that if it wishes for adequate medical care to be bestowed on the poor, it must be prepared to allow market rates of payment, and we hesitate to believe that they wish anything less than skilled service placed at the disposal of old and infirm paupers.

PERSONAL.

SURGEON-GENERAL BOMFORD, Director-General of the Indian Medical Service, has been granted the Distinguished Service award.

WE regret to learn that Major Fullerton, of the Indian Medical Service, has died at Lucknow from blood poisoning, contracted while performing an operation with a pricked finger.

THE Chief Inspector of Factories gives notice that Dr. W. Carroll and Dr. J. H. Thomas have been appointed certifying surgeons for the Rathdowney district of Queen's County, and the Market Harborough district of the County of Leicester respectively.

SIR DONALD CURRIE, G.C.M.G., has given a further sum of £2,000 to the Queen's College, Belfast, in order to complete the sum of £5,000 which is required for the recreation grounds of the College. This gift makes a total of £22,000 which Sir Donald Currie has given to the College.

IT is reported that plague has broken out at San Francisco, and that an active campaign has been instituted in New York against rats in ships coming from South America. The port authorities of the United Kingdom will doubtless follow suit.

A CLINICAL LECTURE

ON

THE CONSEQUENCES AND TREATMENT OF LACERATION OF THE FEMALE PERINEUM.

R. J. KINKEAD, M.D.Dub., L.R.C.S.I.,

Professor of Obstetrics in Queen's College, Galway; Physician and Gynæcologist to the Galway Hospital.

GENTLEMEN.—I have selected for discussion with you to-day the consequences of laceration of the perineum in the female. I do not propose to deal with the risks resulting therefrom during the puerperal period, except to tell you that in every case of laceration in labour, the rent, be it big or little, should be sutured at once; and to quote for you from Dr. MacNaughton Jones' "Diseases of Women," words of wisdom you should imprint on your memories:

"Assuredly if practitioners only recognised the ills, immediate and remote, which follow lacerated perineum, we should less frequently hear of secondary operations. . . . Take it all in all I believe there is not in the entire range of gynæcological practice a point more necessary to insist on than the early closure of the perineal wound after parturition. This caution pertains rather to midwifery than to gynæcology, but it has such an important bearing on the future happiness and comfort of the woman when labour has been long forgotten, that it warrants the stress laid upon it."

In the majority of cases union follows immediate suturing.

In relaxation, and in ununited laceration of the perineum, an enlarged and gaping vaginal orifice results, which by interfering with, or incapacitating from, sexual intercourse affects domestic happiness and tends to promote infidelity. Remedial operation is as imperatively called for in the interests of marital felicity and morality, as it is in those of the woman's physical well-being and her restoration to active useful life.

To understand how disasters arise from its injury, and how they are to be remedied, you must have a clear comprehension of what the perineum is, and of the functions it performs.

For about its upper two-thirds the posterior vaginal wall is contiguous to the rectum, at the lower third, however, the rectum bends back to the anal orifice, while the vagina continues its forward curve, in the space thus formed between the lower end of the rectum and vagina, a triangular mass, composed of strong elastic connective tissue, the perineal body, is interposed, with its base resting on the intersection of four muscles, over which lies the skin.

This skin surface, which you can see, is about one and a half inches long by two in breadth, and extends from the level of the posterior commissure of the vulva to that of the anterior margin of the anus, is usually spoken of as the perineum; and under the mistaken notion that the perineum was only this and nothing more, operations have been recommended and performed for its restoration utterly inefficient, and which had better have been left undone.

"The Transverse perineal muscles cross the base of the perineal body horizontally, between the vaginal outlet and anal orifice, each one fusing with its fellow on the opposite side; a number of the muscular bundles diverge from the horizontal fibres, anteriorly and posteriorly, at angles of about 30°, to fuse in front with the constrictor vaginæ, and behind with the sphincter ani."

When I speak of the perineum, I mean this composite structure of connective tissue, muscles and skin.

The origin of these muscles, the transverse perineal from the tuberosities of the ischium, the constrictor vaginæ from the pubes, and the sphincter ani from the coccyx, being at a higher level than that at which they pass under, and fuse together beneath the perineal body act like C springs, and with every contraction lift that body upwards; while the levator ani arising higher up within the pelvis, passing downwards and backwards to its rectal attachments, not only lifts the rectum, but draws it, the perineal body and the vagina, forwards towards the pubes.

Thus the anterior and posterior walls of the vagina are kept in close contact, and the vagina is maintained as a solid column—the chief factor in supporting the uterus and preventing prolapse.

Lacerations almost invariably occur in the middle line, and run vertically back; they vary in size from an unimportant tear of the fourchette, or, a more serious one, down to or through the sphincter, to a huge rent into the anus, laying open the rectum for one or more inches, and making the vagina and rectum a common cloaca. In the graver cases the perineal body is split vertically, the fusion of the transverse perineals is rent asunder, and the sphincter ani torn across; through the contraction of these muscles, the lacerated tissues are pulled apart. Hence—as I believe, the late Mr. Lawson Tait was the first to point out—while the original tear ran in the anterio-posterior plane of the body the rent heals in the bilateral plane, as shown by the transverse position of the cicatrix.

Thus the vagina is transformed from its normal condition of a solid column, with its posterior wall in apposition with, and supporting, the anterior, into an open tube with an enlarged and gaping vaginal outlet.

When the rectum is laid open, according to the extent of the laceration, there is more or less incontinence of fæces, unfitting the woman for domestic or social life, and rendering her existence miserable.

Whether involving the integrity of the rectal wall or not, the usual consequence of grave laceration is prolapse and procidentia of the vagina and uterus.

Time does not permit me to tell you to-day all the symptoms, and attending ills of rectocele, cystocele and "falling down of the womb."

Suffice it to say they injure the health, give rise to rectal and bladder troubles, and incapacitate the woman from work.

The uterus normally lies diagonally in the pelvis, on the bladder, the cervix pointing backwards. The anterior wall of the vagina is attached to the base of the bladder by cellular tissue, and lower down, more closely to the urethra. When owing to relaxation, or deformity resulting from laceration of the perineum, the support afforded to the anterior vaginal wall is removed, more especially in women, unable to lead restful luxurious lives, but obliged to be on foot most of the day, or to earn their bread by laborious occupations, procidentia may occur suddenly. Usually, however, the process is gradual: under the influence of abdominal pressure and the weight of the urine in the bladder, the anterior wall sags down, and its lower portion containing the urethra protrudes at the vaginal orifice: this is only the first step, and is followed by a descent of more of the vaginal wall with the base of the bladder.

When this occurs the bladder cannot be completely emptied, a pouch being formed below the internal orifice of the urethra. The tendency to descent is now aggravated by the weight of the urine contained in the pouch, and by the force directed downwards into it when the bladder contracts to empty itself.

Bearing in mind that the vagina is attached to the cervix uteri, you will understand that as the anterior wall descends its upper part must pull on the cervical extremity of the uterus, and tend to drag it down, at the same time tilting the body of the uterus up.

Sometimes, however, this does not happen, the uterus remains antiverted, and as an antiverted uterus cannot prolapse, the cervix after a time yields to the strain, and becomes so elongated that we find it and the everted vagina protruded from the vulva, while the body of the uterus remains at its normal elevation in the pelvis.

More frequently the pull brings the uterus first into a vertical position, which facilitates its prolapse, and as it sinks an increased protrusion of both vaginal walls takes place; under the influence of abdominal pressure and the increased vaginal drag, the uterus falls further and further down, changing its direction until it lies in the axis of the outlet, and finally is extruded between the woman's thighs covered by the everted vagina.

As in this lecture I am only dealing with laceration of the perineum, I shall not discuss the other causes of, nor attempt to enumerate the mechanical expedients adopted, and the operations devised to alleviate or cure, prolapse and procidentia uteri.

The object of treatment of laceration should be the cure of its immediate consequences and the prevention of those resulting from neglect. For both, operation is essential, and should be performed as soon as the parts have healed.

Operations for the restoration of the perineum are nearly as numerous as the leaves in Vallombrosa. For my own part I prefer and invariably perform that of the late Mr. Lawson Tait: I have done it in all sorts of cases, with some modifications in dealing with the rent, when the recto-vaginal septum was involved, and am satisfied with the results, which I have found stand the stress of subsequent labours.

I quote for you Mr. Lawson Tait's description of the operation in cases where the laceration does not lay open the rectum.

"Having the folds of the buttocks pulled firmly apart so that the cicatrix is put on the stretch, I enter the point of the scissors at its extreme end on one side and, keeping strictly to its line, I run through to its other extremity. The incision is about ⅜ of an inch deep, and it forms two flaps—a rectal and vaginal. From each end of the incision it is carried forward into the tissues of each labium for about an inch, and again backwards for about ⅓ of an inch.

"The vaginal flap is held upwards (the patient being on her back), and the rectal flap being turned downwards, and the angles of the flaps being pulled by forceps diagonally upward and inward and downward and inward respectively.

"The sides thus become straight, and the wound takes the form of a parallelogram.

"By means of a stout-handled, well-curved needle the silkworm gut sutures are entered on one side about ⅛ of an inch within the margin of the wound (so as not to include the skin). They are buried deep in the tissues, and then the needle is made to emerge so as to miss the upper angle of the wound. The needle again enters at same distance from the angle and emerges ⅛ of an inch from the skin margin on the other side.

"By thus missing the upper or deep angle of the wound, the two great and divided masses of the old perineum, which lie in the parallelogram, respectively bounded by the points of entry and emergence of the needles, are accurately adapted.

"The rectal and vaginal flaps respectively point into the rectum and vagina, and like an old-fashioned flap valve, prevents noxious material entering the wound.

"The resulting mass of the perineum is amazingly large, and union is almost inevitable.

"The resulting cicatrix is absolutely linear, and so resembles the natural raphe, that in three or four months after the operation it is quite impossible to determine from the appearance of the parts that the perineum has ever been injured, for there are no stitch hole marks left to tell the story. I leave the stitches in for three or four weeks, and take care that the rectum and vagina are washed out daily.

"My operation really restores the perineum to its original form and dimension, and makes the patient as good as new.

"That this is so can be seen at once on considering that the transverse incision, in splitting the septum with its small exteniores, fore and aft, really reproduces the original perineal tear, which runs in the anterio-posterior plane of the body.

"The rent has healed in the bilateral plane of the body, as shown by the transverse position of the white line of the cicatrix. The new incision is made in transverse line, but the wound is closed at right angles to it.

"Then as the whole structure of the perineum is opened up and the parts formerly continuous are re-united absolutely in their original position, the torn ends of the sphincters are thus again continuous, and complete functional activity is restored.

"The peculiar method of inserting the sutures is essential to this means, for in this way only can the old relative of parts be restored."

If the recto-vaginal septum is laid open the operation is more complicated.

When the rent extends high up, the upper portion is not affected by the transverse pull of the muscles, and the tear assumes the shape of an inverted V with the apex above.

I split the septum to about an eighth of an inch above the angle of the tear, thus making four flaps—two vaginal and two rectal. The corners of the vaginal flaps are first caught and held up with forceps, and beginning above the angle of the tear, on the raw or rectal aspects the margins of the flaps are sewn together by a continuous suture of fine catgut, the needle being entered a little more than an eighth of an inch from the edge of the tear, and brought out close to, but not through it; it is then entered close to the edge on the other side, and emerges an eighth of an inch from it, care being taken not to perforate the vagina in passing the suture.

By this procedure surfaces an eighth of an inch wide, for the entire length of the tear, are brought into apposition, and the edges project into the vagina.

The rectal flaps on their vaginal aspect are then sutured in the same way, the comparatively broad mass of tissue brought together, and the closely-approximated edges projecting into the rectum, prevent any leakage therefrom into the wound.

The operation is then completed as before described.

I performed this operation with complete success last session in the County Galway Hospital in a case of extreme laceration extending up to Douglas's pouch.

This affection affords an example of the adage that the exception proves the rule; for we meet with cases of ununited laceration in which, with only a narrow portion of tissue between the vulva and anus, the woman seems not a pin's worth the worse. You may ask, should such case be operated on? I unhesitatingly reply they ought to be. The unfortunate possessor of a relaxed vaginal outlet or lacerated perineum is always in a state of danger, for while some may end their days without evil ensuing, in others from sudden strain, over-exertion, ill health, or other causes, disasters may result, and it is much simpler, more certain, and far easier, to prevent prolapse or procidentia than to remedy them once they have occurred.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by G. F. Still, M.A., M.D., F.R.C.P., Professor of Diseases of Children, King's College, London. Subject; "Infantile Diarrhœa."*

University College, London—School Hygiene.

A new course on School Hygiene, including lectures, demonstrations, and practical work, has been arranged to begin on October 16th, at University College. The Course will be given by Professor Henry Kenwood and Dr. H. Meredith Richards. It is designed to meet the requirements of school teachers, school lecturers, and those qualifying for school inspectorships and for school medical officers. A certificate of proficiency will be granted to those who qualify themselves.

ORIGINAL PAPERS.

PHAGOCYTOSIS & BACTERICIDAL ACTION. (a)

G. DEAN, M.B., C.M.Aber.,
Bacteriologist, Lister Institute of Preventive Medicine, London, &c.

Metchnikoff's theory of Phagocytosis is one of the greatest conceptions of modern biology. Combated at the outset by many of the leading pathologists of the time it has steadily gained ground, till now it is almost universally accepted.

It would be impossible to consider as adequate any description of infection, inflammation or immunity which omitted to give a due consideration to phagocytosis. While upholding the cell as the most important factor, Metchnikoff and his pupils could not long overlook the part played by the body fluids in the process of protection.

The work of Nuttall, Pfeiffer and others showed that the blood serum alone in the absence of cells had powerful bactericidal properties. The evidence in favour of this bactericidal action of the serum was so conclusive, and the fundamental experiments were so easily confirmed that the phagocytic theory was for some time overshadowed by the humoral. It soon appeared, however, that bactericidal effects of serum due to bacteriolytic action could not be demonstrated in the case of all organisms, *e.g.*, staphylococcus and streptococcus. According to Metchnikoff this bactericidal action did not play an important part in the living body under normal conditions. The blood plasma did not behave like the serum in this respect. The bactericidal substance had its origin in the phagocyte, and was set free by its death, during the process of clotting, or in the case of the living animal when phagolysis was produced by an excessive dose of bacilli injected experimentally. The bacteriolysis, therefore, was a secondary phenomenon of phagolysis.

On the other hand, in the case of immune animals, there were present in the blood substances which played an important function in aiding phagocytosis. These latter bodies are thermostable and unlike the substance previously referred to, the cytase or complement, which is readily destroyed by a temperature of 56°c.

Two forms of activity have been attributed by Metchnikoff and his pupils to those thermostable bodies. (1) A stimulin action; (2) a fixative action.

When a highly virulent organism is injected into a normal animal the leucocytes do not show any great disposition to attack the invader. The virulent organism tends to repel, or at least, not to attract the phagocyte; in other words, the bacillus has a negative chemiotaxis for the leucocyte. In an immunised animal, on the other hand, no sooner does the virulent organism find an entrance into the body than the leucocytes crowd to the site of infection, surround the invaders, and if the immunity is sufficient, englobe and destroy the enemy. That this property is due to something in the plasma or serum, and not to properties of the leucocytes acquired by education or otherwise, is shown by injecting some of the blood plasma or serum of the immune animal into a normal animal, in which case the leucocytes of the new animal thus passively immunised behave in the same manner as did those of the actively immunised animal. Substances which thus heighten the activity of the leucocytes Metchnikoff has designated "stimulins."

(a) Introduction of Discussion, British Medical Association meeting, Exeter, 1907.

In the second view, the serum is conceived as acting primarily, not on the leucocyte, but rather on the microbe, on which a change is produced, so that it no longer repels, but rather attracts the phagocyte; in other words, its negative chemiotaxis is converted into a positive chemiotaxis.

It would be impossible here to detail even the chief of the earlier contributions on the subject, a brief *résumé* of some of these has been already published by the writer in a former paper.

Interest in these questions had been re-awakened, especially in this country, by the work of Wright and Douglas, who, by a modification of a method devised by Leishman, had made a number of observations emphasising the importance of the serum in the mechanism of phagocytosis, and showing for the first time in an unequivocal manner the fact that normal serum as compared with other fluids, such as normal salt solution, had a powerful action in preparing the microbes for phagocytosis in cases where no bacteriolytic or bactercidal action was apparent.

The substance in serum which had this action, was found to be thermolabile, and was designated by them "opsonin."

In the case of furunculosis, tuberculosis, &c., Wright and Douglas showed that the injection of vaccines made from the appropriate micro-organisms was followed by an increase in the opsonins. The phagocytic method introduced by them attracted many workers, and the fundamental experiment has been repeated and confirmed by many. Much critical investigation will be necessary, however, before the establishment of the claims made as to the value of the method for clinical use.

The nature of the opsonins, their relation to substances previously described and named by others, the value of the method from the clinical standpoint, and the experimental error involved have already been, and must still for some time be, a subject of enquiry for many observers. Such subjects as these would be appropriate for the present discussion.

He then proceeded to review the recent work on these lines, and detailed a number of his own experiments bearing on the subject.

The bulk of the evidence as sifted from the literature and deduced from his own experiments along with those of others, drove him to the conclusion that the opsononising action was due to the effect produced by two bodies acting together: the one thermostable, known variously as the fixateur substance, sensibilisatrice, amboceptor, &c., is the essential substance. It alone is capable of opsonising, but its activity is greatly increased by the presence of free complement, known also as "Cytase," "Alexin," &c. The amboceptor is present in only small quantities in normal serum, hence the apparent thermolability of the "opsonin" in normal serum, whereas in an immune serum the amboceptor plays a predominant part and though heating results in a loss of activity, this is only partial. In both cases the loss is due to the destruction of the complement.

The reason why one type of organism such as the typhoid bacillus is bacteriolysed by the action of these substances, whereas another such as the staphylococcus, though prepared for phagocytosis, without any bacteriolytic effect being apparent, probably arises not from the fundamental difference in the method of action of the serum, or in the substances in the serum which produce the effects, but from a difference in the physical nature of the microbe itself. The experimental basis for these views was fully discussed.

INDICATIONS FOR OPERATION IN CASES OF INTRA-CRANIAL TUMOUR. (a)

J. S. RISIEN RUSSELL, M.D., Edin., F.R.C.P. Lond.

Physician, University College Hospital, London. &c.

DR. RISIEN RUSSELL introduced the Discussion by referring to the importance of diagnosis in which connection he called attention to the possibility of confusing cerebral tumour with disseminate sclerosis, general paralysis of the insane, migraine ophthalmoplégique, and certain other affections, including hysteria, which, in his experience, had been operated upon in mistake for intra-cranial tumour, and emphasised the important points which serve to distinguish these affections from cerebral tumour. In dealing with the conditions under which operation is to be recommended he drew a distinction between cases in which it was advocated with a view to effecting a cure, and those in which it was undertaken merely as a palliative measure. Before advising operation in the first class it was essential that the exact localisation of the tumour should be determined, and this not only in so far as to be able to say that it occupied the brain, as opposed to the cerebellum for instance, but also which cerebral or cerebellar hemisphere, and which part of the hemisphere, was involved. Tumours situated near the surface of the cerebrum, and those occupying one lateral lobe of the cerebellum or the lateral recess, were the most favourable for operation, while those in the mesencephalon, the middle lobe of the cerebellum, notably the anterior portion, and the deeper parts of the cerebral hemispheres, might be regarded as inaccessible from the point of view of the possibility of cure. The probable nature of the growth had an important bearing on the question under consideration, there being always a chance of recurrence in the case of malignant growths, so that they offer less chance of cure than do simple tumours. The prognosis was also less favourable in cases in which diffuse or multiple tumours were present than when the neoplasm was circumscribed or single. In this connection Dr. Russell referred to syphilitic tumours. He laid stress upon the fact that surgical intervention was necessary in a considerable proportion of these cases, and his experience had proved that it was useless to waste valuable time in pushing antisyphilitic treatment when the symptoms were not yielding to mercury and iodide of potassium. Another important consideration was the degree of risk to life from the operation and its immediate effects, and with regard to this he hoped to hear the opinions of some of the surgeons who were taking part in the Discussion. Where other considerations justified the belief that a tumour which had been diagnosed and accurately localised could be successfully reached and removed by the surgeon, he considered that the risk of life ought not to deter the physician from recommending operation. In this connection the amount of permanent defect likely to result from the operation should be taken into consideration. In cases where paralysis was to be expected, and death from the effects of the tumour the only alternative, one could not reasonably hesitate to advise operation, but it was a much more difficult problem when permanent aphasia was likely to result. The majority of people must of necessity hesitate, if indeed they could ever bring themselves to accept an alternative to which death seemed almost preferable. With regard to palliative operations there could be no question as to the beneficial effects of trephining for the relief of abnormal intra-cranial pressure. He emphasised the importance of this procedure as a means of arresting optic neuritis and of saving sight, though it must not be supposed that every patient suffering from optic neuritis had an intra-cranial tumour, or that optic neuritis of toxic origin would be relieved by trephining. In conclusion he referred to the circumstances under which lumbar puncture could be substituted for trephining. It should, however, be regarded only as a palliative measure, which could not be expected to permanently relieve the symptoms. It was valuable as a means of relieving urgent symptoms of pressure, when to wait for a surgeon to trephine would be to allow the patient to die, or when the patient's condition was too bad to permit of the major operation. He also called attention to the importance of the part played by lumbar puncture in the diagnosis of general paralysis of the insane. He considered that it was a procedure which should be employed for diagnostic purposes and the relief of urgent symptoms in cases of intra-cranial tumour, but which should not be regarded as likely to permanently relieve symptoms, prolong life, or effect a cure. In quoting cases in illustration of his remarks he referred to a typical example, in which the diagnosis was easy and the operation successful; another in which, although the operation was successful, the diagnosis was less accurate, in that an intra-medullary cyst of the cerebellum was discovered instead of a tumour external to the organ; a third, in which the diagnosis of tumour seemed certain, and yet this was not discovered at operation, although the patient subsequently recovered from the symptoms which suggested the diagnosis which led to the operation. A fourth case showed how cerebral thrombosis might be readily mistaken for tumour; while in a fifth case, where disseminated sclerosis accounted for the clinical picture, the earlier symptoms strongly suggested a tumour of the mid-brain.

(a) Abstract of Paper to introduce Discussion in the Section o Surgery, British Medical Association, Exeter, 1907.

MR. HARCOURT COATES, M.R.C.S., L.R.C.P., aged 54, of the Hill, Laverstock, Salisbury, consulting surgeon to the Salisbury Infirmary, surgeon to the police, and Medical Officer of Health at Salisbury, has left estate valued at £41,486. He left the residue of his property (about £20,000) to the Salisbury Infirmary, upon trust, to build a wing, or surgical ward, to be known as the "Harcourt and Maud Coates Ward."

DISINFECTION CONSIDERED FROM A MEDICAL, CHEMICAL, AND BACTERIOLOGICAL STANDPOINT (a)

BY S. RIDEAL, D.Sc., F.I.C.

IN opening the discussion on disinfection in its medical, chemical, and bacteriological aspects, I do not think I can do better than very briefly summarise the more recent work on the subject. I have the more pleasure in doing this, and I think you will have more interest, on account of the decided advances that have been made during the last few years in our knowledge of disinfection, of the preparation of disinfectants, and of the proper modes of testing them. However, there are still many points requiring further investigation, and these I shall have also to indicate.

Firstly as to the disinfection itself, the growth of knowledge in the public has to a certain extent eliminated the old idea that it solely consisted in removing smells or disguising them by other odours. An examination of the various disinfectants placed in the hands of our sanitary authorities shows that the majority are several times more potent than carbolic acid, on which formerly such great reliance was placed. Similarly with disinfecting appliances great advances have been made. Dependence is not now so largely placed on aerial disinfection—the air-borne theory being to a large extent exploded—but it is combined with other methods, such as spraying and the removal of infected material as far as possible; in fact, in certain cases the necessity of destruction or steam disinfection of clothes, &c., has been generally recognised; and in place of the disinfection being either inefficient or equivalent to destruction, steam disinfectors can now be obtained which ensure not only safe and adequate heating, but also the complete displacement of the air, which is such an essential factor.

The fallacy of attempting to arrive at or control the germicidal efficiency of disinfectants from chemical analyses has often been pointed out, but on the other hand the hopeless divergency of bacteriological tests was not helpful. The desirability of standardising the test culture in every experiment was emphasized in 1896 by Pearmain and Moor ("Applied Bacteriology," p. 288): "In order, therefore, to obtain some trustworthy datum as to the action of a disinfectant upon a given species of organism, it is desirable at the same time as observations are made upon the disinfectant under examination, to determine the strength and time of exposure required for the disinfection of the particular race on which the examination is conducted when subjected to other common disinfectants." For this purpose they cited mercuric chloride and carbolic acid. In conjunction with Mr. Ainslie Walker, during 1903, I suggested a method—the carbolic acid co-efficient test—as an outline for the standardisation of disinfectants, so that by adopting strict uniformity of procedure and the insertion of carbolic acid as a control in every test, comparable results could be obtained by different observers; and, as the object of considerable discussion, it has happily helped to draw attention to the increasing necessity for some standard bacteriological method for the legal control of the commercial disinfectants.

(a) Paper read at the Conference of the Royal Sanitary Institute in Dublin, June, 1907.

This test has been taken as the basis for disinfectant tender forms by a considerable number of authorities, and the Board of Agriculture in their Disinfection Order (dated April 5th, 1906) now permit the employment of preparations equal in disinfective efficiency to a five per cent. solution of carbolic acid. It has been alleged that the Privy Council Order of July 27th, 1900, permitting the sale without trial of fluids containing less than three per cent. of carbolic acid or its homologues, on the ground that such fluids are not poisons within the meaning of the Pharmacy Act, 1868, has resulted in flooding the market with useless disinfectant preparations. On June 4th this year the question was asked in Parliament as to the necessity for action being taken to ensure the standardisation of disinfectants.

So as to approach as closely as possible the conditions obtained in actual practice, the introduction of a quantity of organic matter into a standard method has been suggested, and recently a number of papers have been published dealing with the results obtained under these conditions. Kenwood, in collaboration with Hewlett, and also Firth and Macfadyen, employed an emulsion of fresh urine and fæces. The effects of the solutions of definite organic substances such as gelatin, casein, peptone, mucin, serum, and also blood and urine have been investigated by Sommerville and Walker. Wynter Blyth, during 1903, in reporting to a committee of this Institute, alluded to the influence on disinfectants of the phenol class through the presence of even small quantities of organic material, and later (*Analyst*, May, 1906) he suggested milk as a suitable organic material for testing purposes, as an easily procured fluid containing a variety of organic and mineral constituents in natural proportions. In a paper read before the Chemical Society in December last he compared the figures obtained by fæces and milk, and claimed that by employing a mixture of whole and separated milk so as to adjust the amount of the fat present, similar curves of results could be obtained.

The complex question of disinfection in the presence of quantities of organic substances may be viewed from many standpoints, and there is again the danger of confusion caused by the multiplicity of results, obtained by many investigators working under entirely different conditions. Fæces are perhaps one of the most variable of organic products, and, as pointed out elsewhere, it is doubtful if the results obtained for example by Wynter Blyth could be duplicated by himself, not to mention other observers. More distinction should be made between organic matter in suspension and that in solution; sterilisation by means of chemicals can be brought about with certainty in the presence of *dissolved* organic matter, but this is not practical with germs protected by being embedded in masses of solids, until the latter are disintegrated. The sterilisation of fæces, for example, is rarely undertaken in actual practice, and after all, beyond temporarily guarding against the spread of infection during transit, such material is better left to its natural disintegration by hydrolysis in the sewage.

It will always be imperative to know for what particular purpose or purposes a disinfectant is required in order to arrive at its proper ultimate valuation, and there can be no doubt that the preparation should be scientifically tested under conditions resembling as closely as possible those that will be present during its application; but it is hopeless attempting to evolve any one single routine test that could apply to the very divergent circumstances obtaining in every-day disinfection—one that would apply equally to the disinfection of a swimming-bath, to the cleansing of cattle trucks, and to the sterilization of surgical instruments. Reaction alone, whether acid or alkaline, plays an important part in disinfection, and some preparations, depending upon a fine emulsion for their germicidal value, are considerably modified by traces of acidity. However, if a preparation that is stated in certain dilutions to destroy disease germs does not kill under the more simple conditions as those of the carbolic acid co-efficient test, it is worse than useless for any disinfectant purposes, and as a fraud its sale should be prohibited. It would be wrong to illegalise certain powerful germicides because they are rendered uncertain in their action by large quantities of organic matter, and it is surprising to find in a paper published this year such a miscellaneous list as preparations of "permanganate of potassium, eucalyptus, thymol, boric acid, chloride of lime," generally condemned as being "erroneously believed by the public to be disinfectants."

Certain oxidizing agents, such as chlorine, which attack organic matter, are not necessarily rendered ineffectual by an excess of organic material, as I have shown when disinfecting sewage effluents with electrolytic chlorine at Guildford, the pathogenic organisms were killed, even if there were sufficient organic matter present to completely remove in a few hours all the free or available chlorine added; and provided that the re-agent is added in excess of that almost immediately taken up by powerful and rapidly reducing substances, such as sulphuretted hydrogen, that may be present, the majority of the bacteria are destroyed.

It is singular that the question of time in a standard bacteriological test has not met with more attention, as although, given sufficient time, many chemicals will destroy bacteria, a limit of fifteen minutes throws out some well-recognised germicides; as an instance soap, which does not give any carbolic co-efficient, and yet has marked germicidal properties, and perhaps would with advantage displace a few disinfectant preparations which have been put on the market. Many of our most reliable disinfectant substances are unfortunately incompatible with soap, and in ignorant hands this causes great waste. Disinfection cannot replace care and cleanliness, but is at times a necessary auxiliary to them. The very act of cleaning with soap and water is in itself a form of disinfection; but occasionally more active measures are required, and when there is danger of personal infection the whole procedure should be under proper scientific control. Where there is much organic dirt it should first be removed with precaution and cremated; by doing this the greatest economy and efficiency in the subsequent disinfection is secured. Indiscriminate scattering of costly disinfectants on masses of filth is useless and wasteful.

The necessity for the power of penetration is a factor which cannot be overlooked in a disinfectant, but it is reasonable *first of all* to inquire whether the preparation will destroy the germ when it reaches it. By reason of the complexity of the subject, no satisfactory routine test has yet been devised to measure penetration.

The high germicidal values given to certain substances, notably salts of mercury, by earlier observers have been considerably modified recently. Previous fallacious results were mainly due to the carrying over of traces of the powerful germicides into the sub-cultures, the great difference between an antiseptic and a disinfectant dose not always being allowed for. This difficulty which also arises in using resistant spores as test organisms can be overcome in the case of simple chemicals, such as metallic salts, by the addition of suitable precipitants to the cultures, but the traces of the more complex phenol derivatives cannot be so certainly removed.

THE REDUCTION OF INFANT MORTALITY,

BY BETTER MANAGEMENT AND CONTROL OF THE MILK SUPPLY. (a)

By HENRY KENWOOD, M.B., D.P.H.,

Professor of Public Health, University College, London.

A VERY large percentage of infant deaths from zymotic diarrhœa has been attributed to artificial feeding, and condensed milk has been held to be much more dangerous than raw cows' milk. These conclusions have been arrived at from a statistical comparison of the infant deaths from zymotic diarrhœa on the basis of the method of feeding prior to death. Incontrovertible as these facts are as statistical statements, they do not, of course, afford a true quantitative expression of the extent to which milk *alone* is the determining factor of the higher mortality among those who have been artificially fed, because other important factors capable of variation in the two classes compared are ignored.

Any mere statistical comparison, on the basis above referred to, may be equally misleading when it is used to demonstrate the extent of the value of municipal milk depôts, as agencies in the reduction of infantile mortality; for our experience in Stoke Newington points clearly to the fact that the hand-fed infants, as compared with the breast-fed, are generally more handicapped by other circumstances that largely determine the matter of the survival of the infant. I refer to a lesser degree of maternal care (and, in consequence, a greater neglect), and to those circumstances associated with extreme poverty (including insufficient food, neglect to seek and obtain medical advice, insanitary environment, etc.). It is therefore extremely difficult to gauge the true proportion of those deaths that are due to hand-feeding *per se;* but there can be no doubt that the number is very considerable, and that it constitutes an appalling annual toll exacted by maternal ignorance and dirty milk.

But, despite all our efforts to foster breast-feeding, a large proportion of infants will continue to be artificially fed, and public health interests demand a guarantee of healthy cows, a sufficient standard of cleanliness of milk and the discontinuance of the very general practice in summer months of drugging it with chemical preservatives.

The milk trade does not realise to the full that theirs is unique amongst trades, inasmuch as it deals with a necessary article of food which forms the almost exclusive diet of a large proportion of the most susceptible units of the population (the infants and invalids), and that milk is unique, as an article of food, in its powers of collecting and fostering micro-organisms which are injurious to health and may be fatal to the infant consumer. It is an extremely responsible trade, and it is an exceptionally difficult one to conduct. But the public, enlightened and stimulated by those who guard their health interests, are demanding, with increasing concern, that those engaged in the milk trade shall do more to protect them. It is not an unreasonable demand, and those who fail to respond to it not only neglect an obvious duty which they owe to the community, but it is inevitable in the near future that they shall suffer from the consequences of their neglect. It is the fit alone who will survive, for the milk trade will have to be raised to a much higher standard of ideal and accomplishment. It is, moreover, greatly in the interest of the trade that the milk supply should satisfy a legitimate demand for the greatest possible purity, and that it should cease to be regarded as a not infrequent danger to infant health and life.

The greatest difficulty which has to be confronted is the ignorance at the fountain-head—the average country dairy farm. The majority of dairy farmers have made little educational advance during recent years in their appreciation of the necessity of greater care and better provision for guarding the cleanliness of milk, and the actual milkers have rather deteriorated than improved with the greater difficulty experienced in obtaining that class of labour. During a recent visit to Denmark I was struck with the greater intelligence and the better supervision exercised over the milkers by the Danish dairy farmers compared with what has been my general experience in this country. The more backward British dairy farmer will, like the Dane, improve under the stimulus of a sufficient supervision and inspection, and by the insistence among those whom he supplies of a higher standard of cleanliness of the milk.

It would be a good thing if a simple limit of dirt could be fixed, which when exceeded would warrant the condemnation of the milk as dangerous for use; the consignee would return any milk which does not reach the standard, and the farmer would then soon learn the lesson of the necessity for greater cleanliness, and where neither he nor any member of his family assisted in the milking operation, he would find it in his interest to at least exercise the necessary supervision over those who do the work. To put it mildly, too often only the most rudimentary precautions are taken at the fountain-head, and the slovenly methods of the past must make way for more cleanly ones, which involve the minute attention to detail which comes with an educated cleanliness. The state of filters and separators after use is eloquent testimony to the need for reforms. The suggestion for a diet standard (based on pus or blood cells and the volume of dirt that can be separated) has met with a wide approval, and is one of the possibilities of the near future. Excessive bacteria generally imply excessive dirt, and dirt is as bad as adulteration, if not worse.

I realise that under no conceivable conditions can we hope in general practice to collect milk which is not planted with many hundreds of micro-organisms to the c.c.; but the fact remains that by greater efforts to reduce the number of extraneous organisms which now get into the milk at the time of collection, and by preventing those from unduly multiplying in the interval of collection and distribution to the public, we should achieve a valuable and vital improvement in the purity of the milk. It is this *improvement at the source* which is so much demanded, for the excessive contamination *there* either handicaps or nullifies all the subsequent precautions which may be taken.

It is to the dicta of their trade organisation that the country dairymen and dairy farmers will turn the most willing ear. The better class dairymen have done much to educate their own farmers, and would not the Dairy Association do valuable work by publishing detailed dairy rules, somewhat of the nature of those issued by the United States Department of Agriculture, 1900, and founded on the advice offered in the published leaflets of our own Board of Agriculture?

It has often impressed me as a most discreditable circumstance in our sanitary administration that the legal powers which it is competent for any rural sanitary authority to execute have either been so ignored or badly administered that in the rural districts, where the bulk of our milk comes from, there

---

(a) Abstract of paper read in the State Medicine Section at the Exeter meeting of the British Medical Association, August, 1907.

exists practically nothing worthy of the name of a sanitary supervision of dairy farms. By consequence the larger milk dealers have had to step into the breach, and in order to protect themselves and their customers from the consequences of the neglect of the proper authorities, have taken upon themselves these duties; and it is no exaggeration to state that the requirements and conditions imposed by up-to-date milk vendors under their contracts with the farmers, furnish an object-lesson of what can and ought to be done, to the best organised and most advanced rural sanitary authority in this country. But this is an unfair tax upon the milk trade, and if rural sanitary authorities did their duty it would be unnecessary. From information obtained in 1903 by the *British Medical Journal* from Medical Officers of Health of counties and of combined sanitary districts, it appeared that in England and Wales, as a whole, some 30 per cent. of the sanitary authorities had made no regulations under the Dairy and Cowsheds' and Milkshops' Order, 1885; that very few of those who made regulations had provided efficient means for the supervision which is necessary to ensure that they are carried out; and that under the Order of 1889 (for dealing with tuberculosis of the udder) only four had arranged for any measure of veterinary inspection of milch-cows.

This year Mr. Burns made a statement in the House of Commons to the effect that there are at present some 20 per cent. of authorities without the regulations empowered in 1885—20 years ago!

All local authorities should be compelled to adopt and enforce suitable and sufficient regulations, and the Local Government Board should appoint inspectors to see that these are enforced. Moreover, a Bill should be drawn up for the purpose of empowering the County Councils to supervise the execution of the regulations and to take over and execute the powers of defaulting authorities and to charge the expenses to defaulting districts.

It is clear that the fundamental difficulty in obtaining these most necessary reforms is that the sanitary authority who administers the law in rural districts generally consists of those who have the least interest in making it effective, and who often deliberately make it lax, because the adoption and proper enforcement of the existing powers at their disposal would affect their pockets. It is this circumstance which gives great weight to the plea for making the responsibility for the necessary control and inspection of the milk industry a central and national one; and a further argument is the circumstance that otherwise the conditions imposed will vary in their stringency in different districts, and thus affect the trade unequally and unfairly. In default of such a national control the County Councils and County Boroughs must be charged with special powers and duties in this connection—an alternative which, while presenting advantages over existing conditions, is immeasurably inferior to a central control for the whole country. Why, in any event, should not the execution of the above-mentioned powers be subject to more supervision by a Government Department? They transcend in their importance to the public health the legislation dealing with the sale of food and drugs, yet in this matter the central authority keeps in close touch with all local authorities, frequently making representations with reference to the administration of the Acts, and giving advice upon the difficulties encountered; but our milk supply is comparatively neglected by them.

You will agree with me that another very necessary reform is the annual licensing of all premises where milk is either sold or collected or prepared for the purpose of sale. This has already received legal sanction in the Liverpool Improvement Act, which dates as far back as 1867. The conditions of the initial grant of the licence must be the suitability of the premises and the sufficiency of the general arrangements for the important purposes to which they are put, and the annual renewal must be conditional upon the maintenance of these at a satisfactory sanitary standard. There is another precedent for this in the annual licensing of slaughter-houses, and none will dispute the greater claims which may be urged in favour of licensing dairies and shops where milk is sold. The provision would, of course, apply to dairy farm premises, none of which should be licensed unless adequate arrangements exist for cooling the milk; and under its operations it is to be hoped that milk will no longer be sold in shops fully exposed to dust and flies, and more particularly in such places as chandlers' shops.

Such a requirement would not hit anyone who was conducting the business with due regard to the bare necessities of the case, but it would eliminate a few from the trade who should not be allowed to continue to carry it on to the public danger. It is not necessary that the premises licensed should be structurally elaborate; elaborate cleanliness is what is wanted; and the means for securing this, and the evidence of a conscientious and intelligent effort to maintain it, should determine the granting and renewal of such licences.

The arguments in support of the frequent veterinary inspection of cows the milk of which is used for human consumption (whether as milk, cream or butter) is overwhelming.

I believe that you will agree that such an inspection cannot be provided by the rural and small urban sanitary authorities, for many reasons, and it certainly would not be fair to saddle all the expenses involved upon the dairy districts. Failing these authorities, the duties would devolve upon the County Councils, and, failing them, upon the Local Government Board or the Board of Agriculture. Personally, I should favour a system of quarterly inspection under one of the latter boards, but it might be undertaken by the County Councils and the County Boroughs, and I would give them power to act quite independently of the local sanitary authorities. But some fair measure of compensation should be provided (as under the London County Council (General Powers) Act, 1904), when animals infected with tuberculosis have to be removed from the herd and slaughtered. I am out of sympathy with the antagonism evinced in many quarters against a fair measure of compensation in such a scheme. The cost, having regard to the important issues at stake, and to the fact that it would remove the formidable barrier which trade opposition can erect against legislative action, is small, and would tend to grow smaller year by year, and without it the scheme of veterinary inspection will be under a great disability. Under most milk contracts with farmers the farmer is exempted from any loss which might result from his giving prompt information of the existence of infectious disease in anyone connected with the cows and the milk. This is found to be a valuable concession as guaranteeing that the necessary information will not be withheld; it is for a similar reason that I advocate compensation for the compulsory slaughter of the milch cows, and my advocacy is strengthened by the circumstance that the clinical diagnosis of tuberculosis is often very difficult. I would not advocate a full measure of compensation, for some loss upon a tuberculous animal will serve as a stimulus to many farmers to be more careful what they buy, and to do more (especially in the matter of the ventilation of the sheds) to keep cows free from this disease. To further the ends of this necessary veterinary inspection, the Board of Agriculture should make tuberculosis in milch cows a notifiable disease, and it is not too much to require that farmers should be compelled, under a penalty, to notify any udder diseases in a milch cow, and to refrain temporarily from selling the milk of cows so affected, pending the veterinary inspection. The scope which at present exists for reduction of tuberculosis in bovines, without seriously interfering with the conduction of the trade or increasing the cost of the milk to the public, is demonstrated by the operation of the L.C.C. and Manchester Milk Clauses, the latter Act having led to a reduction of the number of tubercular samples sold by over 40 per cent.

But all along the line there is need for reform, and for many reforms which the trade itself should do more to promote. Time, however, demands that I should conclude my opening remarks within a few minutes, and those I propose to devote to a very important issue of the milk question. Although I am confident of great advances in the near future, I do not expect to see such a measure of improvement as would lead me to recommend the feeding of infants with raw milk in the summer months, when Pasteurisation appeals to me as a measure of enormous public health value, as much preventable disease would thereby be prevented, and we should have no more drugging of milk with chemical preservatives. And as the contamination of the milk in the home is a circumstance which is responsible for much of the evil consequences of the consumption of raw milk in the summer months, I am confident that before long all milk will be sold in bottles. This represents an important advance in the right direction, when the proper means are provided for thoroughly cleansing the bottles by steam under pressure, and for filling them at headquarters. The bottle protects against the access of dust and flies before and after the milk reaches the home, and it is almost a guarantee of unwatered milk and of full measure.

I believe that in no other civilised community is raw milk consumed in such proportion as in our own country, and yet practically all leading authorities in this and other countries inveigh against its use, especially in the summer months. Is it not clear, then, that in the interests of preventive medicine we should make the dangers of artificial feeding the argument for obtaining breast-feeding whenever possible; but, failing that, we should discourage the employment of raw milk for infant-rearing until we attain to (if it is attainable in general practice) an absolutely pure milk supply? But although we shall certainly much reduce the dirt in milk, it is inconceivable that we shall ever do away with it entirely. Even with a much-vaunted supply in Copenhagen, I was astonished to see the large amount of dirt present in the milk arriving at the depôt. Now the alternative to raw milk is to heat it to a temperature which represents Pasteurisation or to the far higher temperature of sterilisation.

With regard to the prolonged use of sterilised milk, it is conceded that some danger exists, but there is a tendency to a great exaggeration of the danger in this country. This is the view of many competent authorities with whom I have discussed the subject, and the following facts support the view.

What is the experience in this country? There are each year many thousands of infants up and down the country who are fed upon sterilised milk, and there has been for some years a large market for such milk; the use of (sterilised) condensed milk for infant feeding is also a very extensive one; yet the testimony to its evil effects is trifling. The bulk of the milk supplied at institutions to infants in this country is either sterilised or Pasteurised, and wherever sterilised milk has been given out in infant milk depôts there has been no mention of infantile scurvy. But the Registrar-General's reports afford perhaps the best justification for the pronouncement in favour of the harmlessness of sterilised milk, for, despite the extent to which it is used at the present day in this country, we find that only ten deaths occurred from scurvy among infants under one year of age in the vast community of London during the three years 1903, 1904, and 1905, whereas for every such death about 800 deaths were certified from diarrhœa (stated to be due to food), epidemic diarrhœa and infantile enteritis, and diarrhœa (not otherwise defined).

What is the experience abroad? In America, Denmark and France, each with an extensive experience covering many years, the verdict is favourable to sterilised milk. Dr. Variot, whose experience is unique, since his feeding experiments at the "Goutte de Lait," at Belleville relate to over *3,000 healthy as well as unhealthy children who were closely observed by him for many months*, has seen nothing of infantile scurvy resulting from the use of sterilised milk. The facts collected from the experience of other such institutions abroad, and from the Consultations des Nourissons in France, are further testimony to the almost absolute harmlessness of sterilised milk. On all sides the general experience is that extremely little scurvy results from the use of such milk, and the late Professor Budin, whose "Consultations" are now established all over France, and were first started in 1892 with the object of advising and helping French mothers in the healthy rearing of children, wrote to me under date April 6th, 1906, that as the outcome of his wide experience he had not seen a single case of infantile scurvy resulting from the use of sterilised milk.

This is not the place to discuss the etiological relationship of the prolonged use of sterilised milk to scurvy in the infant, but the absence of that unknown quantity, "the anti-scorbutic principle," can only at most affect those patients with a very rare idiosyncrasy. But although it is granted that the use of sterilised and boiled milk occasionally harms a child (for this is testified to by those whose findings are authoritative and beyond dispute), it cannot be in the public interest to discourage its use in face of the overwhelmingly greater dangers of raw milk. If one sets the danger of sterilised and boiled milk against that of the raw article, the former danger sinks into insignificance by the side of the latter. Those who rail against the use of sterilised milk say, in effect, that rather than one child should suffer from scurvy, some hundreds may be left to die of zymotic diarrhœa, etc. There is, however, practically no evidence that Pasteurised milk has caused infantile scurvy, and it possesses the additional advantages over sterilised milk that its taste is unaltered, the physical changes brought about by Pasteurisation are practically nil, and the digestibility is not impaired; and, furthermore, Pasteurised milk is consumed in a fresher condition than sterilised milk.

As to the provision of municipal milk depôts, I am not, I must confess, enthusiastic. That they are valuable object-lessons to the community (including the trade) I have no doubt, but I believe that educationally and sociologically the provision of infant consultations, as inaugurated by the late Professor Budin, are to be preferred. Such provision was made a little more than a year ago at the St. Marylebone General Dispensary, London, and the results appear to be (so far as one can judge from statistics) at least as good as those obtained from the Metropolitan municipal milk depôts. Through the efforts of Dr. Sykes, "A Mothers' and Babies' Welcome," with similar aims to those of the "Infant Consultations," has recently been established in St. Pancras, London, and is doing excellent work. I am of opinion that the mothers should be left to obtain the milk through the ordinary commercial channels, and that those milk vendors should be recommended who are willing to conform to the conditions imposed by the directors of the Consultation.

In conclusion, I know that there is among medical men a general agreement with my main contentions, and yet in this, as in other matters, we muddle along and delay the day when the full beneficent results of our knowledge will be reaped.

The President of the Local Government Board has stated that he proposes to make legislative proposals on his own account next year. At the risk of being judged presumptuous, I would suggest that what is wanted more particularly is *stringent* legislation, embracing, above all, a scheme of *efficient inspection* of dairy farms and milch-cows; and, with reference to certain matters that do not lend themselves to effective legislation, an authoritative pronouncement by the Local Government Board. As to the matters referred to in the latter category, let me remind him that in other countries neither the public nor the trade is left in doubt that what is the correct thing to do is to avoid the use of raw milk, at least in the summer months, and Pasteurisation and sterilisation is encouraged. Those responsible for the public health in New York and some other American States have made no secret of their preference for Pasteurised milk. The consequence is that the trade has responded, and a considerable reduction in infantile mortality is claimed as the result of its very general use. In France they have made up their minds on the subject, and the French Minister of Public Instruction has advocated the use of Pasteurised, boiled or sterilised milk as a precaution against disease. The central authorities in Denmark and Germany have also given advice on the subject. But in this country no such lead is given. If the public were informed by a Government department what it is they ought to demand, the trade (at present distracted by all sorts of conflicting views and statements) would the sooner fall into line.

OPERATING THEATRES.

KING'S COLLEGE HOSPITAL.

Operation for Ruptured Gastric Ulcer.—Mr. **Peyton Beale** operated on a coachman, æt. about 35, who had been admitted, under the following circumstances: at two o'clock in the afternoon, having had no food since breakfast, he was seized with sudden and very severe pain in the abdomen; it started in the lower part in the region of the bladder, then extended to the right iliac region and right loin, and when he was admitted at about 3 p.m., was found to be most severe in the gall bladder region. There was a history of rheumatic fever, and the man had aortic and mitral murmurs. His chief complaint was difficulty of breathing. The pain was so severe that he was obliged to sit up, and he was sweating profusely. He was admitted and ordered to be kept very warm, and fomentations were applied over the abdomen. He vomited once only, bringing up some bile-stained fluid. There was practically no distension of the abdomen, but there was very well marked dulness in both flanks. At 8 p.m., about five hours after admission, his condition was as follows: pain localised to the epigastrium, slight abdominal distension, marked dulness in both flanks, no vomiting, temperature 99, and tending to rise, pulse 120, considerable respiratory difficulty except when sitting up. He had given an old history of indigestion extending over some months, but at no time had he suffered from hæmatemesis or from melæna. It was considered advisable to explore the abdomen at once, so, the usual preparations having been made, the abdomen was opened in the right linea semilunaris. A quantity of turbid fluid at once escaped, and there was little doubt that this came from the stomach. On inserting the hand into the abdomen and exploring the stomach, a perforated ulcer about the size of a threepenny piece was detected in the smaller curvature of the viscus close to the pylorus. This was with some difficulty brought to view, its edges were rapidly excised and several sutures introduced in order to approximate the borders; more sutures were then used to bring together the peritoneal covering of the stomach and thus to close over the line of previous sutures. The stomach was next explored, but no other ulcer could be detected. The abdominal cavity was then washed out very freely with hot sterile salt solution and the abdominal wound closed, two gauze drains being inserted at each extremity. The patient was put to bed and ordered to be given as much morphia as might be necessary to keep him absolutely quiet. The whole operation lasted about twenty minutes. Mr. Beale said that in his experience the elements of success in these cases rested upon the carrying out of the following conditions: First, to operate at the earliest possible moment, even though there was considerable doubt as to the diagnosis, confirmation of the diagnosis often not being obtained until general peritonitis was well advanced, to wait until this occurred was, of course, in most cases fatal; secondly, to operate as quickly as possible, and not to insert more sutures than were absolutely necessary to approximate the freshened edges of the ulcer. If the ulcer were larger than a threepenny piece, it was always wiser and really quicker in the end to open the stomach freely on its anterior aspect and sew up the ulcer from within, subsequently closing the stomach incision with a continuous suture; this procedure was, of course, always necessary when the ulcer was situated at all posteriorly. The process of dragging the stomach up in order to reach the ulcer in the ordinary way was, he considered, very dangerous. Thirdly, to operate in a very hot room or theatre, to have all instruments and lotions as hot as possible, for he was perfectly convinced that the greater part, if not the whole, of the shock subsequent to abdominal operations was due to exposure to cold; fourthly, to keep the patient fully under morphia for two or three days after operation, that is to say, to administer sufficient morphia to keep the patient perfectly quiet.

Paris, Aug. 18th, 1907.

Exophthalmic Goitre.

Numerous are the theories put forward relative to the cause of exophthalmic goitre, but only two of the group claim attention—nerve and thyroidian theories. The former incriminates either an affection of the bulb or of the sympathetic system.

Authors who pronounce in favour of disorders of the bulb invoke the co-existence of cardiac troubles, vaso-motor troubles on which might depend the goitre (congestion of the thyroid), and exophthalmia and the trembling, from paralysis of the cranial nerves.

The theory which attaches Graves' disease to a lesion of the cervical sympathetic is based on the theories of Claude Bernard and more particularly those of Abadie. For Abadie, there existed a permanent excitation of the vaso-dilating fibres of the cervical sympathetic or of their nuclei. The origin of the vaso-constrictors being abolished, the carotid arteries and those of the thyroid gland, dilate, and the result is hypertrophy of the gland from turgescence of its arteries, hence goitre; the vessels of the bulb dilate also, hence exophthalmia. As to tachycardia, it is the direct result of the disturbance of the great sympathetic. Thus, the three great symptoms of the malady are easily explained.

Plausible though it be, this theory is being gradually abandoned as lesions of the sympathetic are far from being constant in Graves' disease, and, according to Francois Franck, the sympathetic exercises no vaso-dilating action on the thyroid body. Yet the conception of Abadie deserved mention, as it had as a consequence, originated the surgical treatment of exophthalmic goitre by section of the cervical sympathetic.

Much more important would be the thyroidian theories, which are two in number, one sustained by Ganthier, incriminating perversion of the secretion of the gland, the other exaggeration of this secretion (Mōbius).

The last-named is based on clinical facts. In myxœdema, which results from thyroidian insufficiency symptoms are observed (atrophy of the thyroid body, sensation of cold, lowering of the central temperature, dryness of the skin) which are exactly the reverse of the symptoms of Basedow's disease. On the other hand, MM. Ballet and Enriquez reproduced, by injecting thyroid extract into sheep, a certain number of signs of exophthalmic goitre.

For M. Boix, neither of these theories should be considered absolute, as we have not yet arrived at a perfect knowledge of the nature and cause of the malady.

Treatment.

The treatment is either medical or surgical. The medical treatment is very important, and can, if properly carried out, cure the patient. Absolute rest in bed should be prescribed, where the symptoms present the slightest gravity; this means alone are sufficient to moderate the cardiac palpitations and the nervous agitation. In every case, the patient should be guaranteed from all excitement and brain worry. Country air is very beneficial, but a sojourn at the seaside is counter-indicated.

As to medical treatment proper, digitalis has been prescribed for palpitations.

Trousseau recommended it in large doses until symptoms of intolerance set in, while Jouffroy recommended strophanthus. But Dieulafoy considered either of these drugs as more or less hurtful, and they should be reserved for cases of weakness of the cardiac muscle, with dilatation of the cavities and a tendency to asystolia. He prescribes, on the other hand, ipecacuanha.

Hippo powder, 1 gr.
Digitalis, ½ gr.
Ext. of opium, 1-10th gr.

For one pill. Two, three, or four daily, and continued for months.

Agitation and insomnia are best treated by bromides or valerian and febrile attacks by antipyrine (Huchard), salicylate of soda (20 gr. four times daily) gave good results in the hands of Chibret and Babinski.

Hypertrophy of the thyroid body has been treated by iodine and iodides, but, according to Dieulafoy they do more harm than good. The same might be said of ferruginous preparations.

Among physical agents, hydrotherapy procures frequently excellent results. The cold douche may be ordered, but in order to accustom the patient to the cold water, warm douches might be given for the first two or three days.

Electricity is one of the best therapeutical agents; it is local and consists of two great methods—that of Eichorst, utilizing galvanisation, and that of Vigouroux, employing Faradisation; they may be associated.

The seance may be commenced by galvanisation, one plate on the tumour, the other on the back of the neck. The seance should be from one to ten minutes, according to the tolerance of the patient. Then Faradisation of the orbicular region, the sides of the neck and the precordial region should follow.

The duration of the electric treatment is from three to four months. Decrease of the goitre, attenuation of the trembling, improvement of the general condition, are frequently observed after the first few seances. According to Delherm, improvement in the palpitations and the exophthalmia is much slower.

As to opotherapy, it has but little place in the treatment of exophthalmic goitre; iodo-thyrine would be only beneficial where the malady depended on defect of the secretion of the thyroid gland, which is far from being proved.

Gilbert Ballet and Enriquez imagined an immunising serum taken from the horse or the sheep, from which they had previously removed the thyroid gland. Mixed with glycerine and given at the dose of three teaspoonsful a day, it has given encouraging results. All the symptoms improved rapidly—goitre, palpitation, exophthalmia and trembling.

The surgical treatment consists in total or partial thyroidectomy, resection of the cervical sympathetic, operations which may be regarded as generally useless, and should be only counselled as a last resource.

The treatment of Graves' disease requires great patience, and the physician should know how to vary his treatment according to the particular case. But if intelligently applied, the treatment procures in the large majority of cases, if not a complete cure, considerable improvement and prolonged remissions.

GERMANY.

Berlin, Aug. 18th, 1907.

At the German Society for Surgery, Hr. Kausch, Berlin, discussed the subject of

Contracted Bladder and its Treatment.

He first described the various causes of the abnormally small bladder (congenital, neuroses, affections running their course outside bladder, inflammatory growths, tumours lying within the bladder, and calculi; concentric hypertrophy). By far the most frequent cause was interstitial cystitis with disappearance of the muscular walls (contracted bladder). The condition of the severe cases in which the bladder capacity fell to 10-20 ccm was intolerable; at last all the patients died with ascending inflammation.

The treatment consisted in dilatation of the bladder; this, however, when inflammation was present or when it supervened was out of the question and did no good. In one case a suprapubic fistula was formed and the sufferings of the patient were very much diminished.

The speaker in one case, that would be more fully related, had totally disconnected a loop of small intestine and brought it into connection with the bladder, the capacity of which was only 20 ccm. The patient was discharged cured, continent, with a capacity of 200 ccm. The procedure might be advisable in cases that could not be relieved in any other way or in which the bladder had been totally or almost totally extirpated.

Hr. Schmitt, Munich, observed that none of the operations at present employed secured complete continence. Maydl's method of implanting the ureters into the bowel still gave the best results.

Hr. H. Jacoby, Berlin, showed apparatus for stereocystoscopy and stereocysto-photography and also photographs produced by them.

Hr. Ringleb, Berlin, believed that vision was not stereoscopic with the apparatus shown, but that with Nitze's instrument it was easy with practice. It was not to be denied, however, that stereocysto-photography was an important advance.

Hr. Körte, Berlin, had performed Maydl's operation in one case, continence was not complete, but the patient was very much improved.

Hr. Kümmell, Hamburg, greeted Rovsing's method of performing total extirpation of the bladder as an important advance. Total extirpation of the bladder for carcinoma was always very fatal. In two non-carcinomatous cases the results were better; in one case death took place 4 years after from ascending disease; in the second case, that of a boy, death took place in a year.

Hr. Riedel, Jena, had been successful in one case; a second one died of ascending pyelitis.

Hr. H. Stettiner, Berlin, showed a case of

Multiple Intestinal Atresia.

The patient, an infant æt. 13 months, presented the deformity of Atresia ani urethralis or Atresia ani et communicatio recti cum parte prostatica urethræ as Stieda called this form of malformation. The first operation was performed on the second day after the birth of the child, and consisted in making an opening to the blind end of the rectum and suturing it to the place where the anus should have been. The second operation was performed four weeks afterwards, the object of which was the abolishment of the communication. Here also the operation was performed from the perineum. The urethra tore at the point of communication and a Nélaton's catheter had to be sutured in. The opening in the rectum was also closed and the operation concluded with a procto-plastique. A perineal urinary fistula formed at first but closed later. Urination was now normal, the bowel function was not perfect but satisfactory. Communications of the blind end of the rectum with the urinary organs were met with at three spots, most rarely at the summit of the bladder, most frequency at the base, and thirdly at the prostatic part of the urethra. Whilst the first named malformation required laparotomy, separation of rectum and bladder, suture and pushing down of the blind sac to the perineum with proctoplastique, such as Lotsch had lately carried out successfully in a case, with deeper seated communications the operation should be carried out from the perineum. He would do the operation at two separate sittings but would not put off the second to a later age, but at the most for two to six weeks after the first part.

He also showed the bowel of a child with multiple stenoses on which the operation for artificial anus had been performed 24 hours after birth, but which died 60 hours after the operation. At the *post-mortem* it was found that the small intestine ended in a blind sac 75 cm. below the pylorus. This blind end lay in a tangle of matted loops in which the blind end of the further portion of the small intestine lay. This was at first much dilated, and it was here that the artificial anus was made. Next to this was a mass of thin twisted serpentine loops, then the normal colon with a large vermiform appendix and the rectum only the size of a pen holder. There was also a good deal of peritonitis probably secondary. It would have been better to have operated from the abdomen so that the requirements of the case could have been met.

AUSTRIA.

Vienna, Aug. 18th, 1907.

A New Function of the Pancreas.

Professor Loewi, in a long paper read before the members of the Gesellschaft, raised a new point in connection with diabetes mellitus, which had been excited in his own mind by the experiments of Eckhard, who demonstrated a short time ago that, if the sympathetic could be inhibited, irritation of the nerve, either centrally or peripherally, would produce sugar in the urine by the transformation of glycogen. If the pancreas possesses this function alone of irritating the sympathetic which has been proved to cure the diabetes in some experiments, by its removal, we have in our hands a speedy remedy for the disease. With this argument in view, Loewi commenced the examination of the hypothesis from another point. The dilator muscle of the pupil of the eye is the best index of the sympathetic at our command. If adrenalin be dropped into the normal eye no mydriasis will appear, as this drug stimulates the motor fibres of the sympathetic; but if the cervical ganglion be removed twenty-four hours before dropping in the adrenalin, mydriasis will appear. Now of 18 diabetic patients to whom Professor Loewi administered the adrenalin to, 10 of them suffered afterwards from mydriasis. Of 28 other patients suffering from other diseases, only two had mydriasis, viz., one suffering from occlusion of the pancreatic duct according to clinical diagnosis, but no glycosuria was present. From this he assumed that the two functions of the pancreas can be separated. The other case that acted was one suffering from morbus Basedowi, which from this reaction may have some close connection through the sympathetic nerve system.

Freund thought this an important contribution to our knowledge on a very abstruse and obscure subject in medicine. From a chemical standpoint, Professor Loewi's theory was interesting. We have a series of clinical observations very conflicting when an attempt is made to reduce them to order but if a chemical insufficiency in the hepatic cells be accepted this would interfere with the function of the organ and prevent the sugar being converted into glycogen. In 1902 he had a considerable amount of discussion and examination of cases which resulted in the opinion that different forms of diabetes mellitus were due to vascular paralysis, supposed to be due to central irritation as well as peripheral, causing a dilatation of the vessels that had no power to contract. Toxins and antitoxins possessed the same property of paralysing.

Falta thought that Professor Loewi's theory had a wider interpretation as it could be extended to the Naunyn school, which believed in the disturbance of glycogenic circle by the loss of power in the lung to burn up the superfluous grape sugar. Freund's chemical theory might be true of slight or simple forms of diabetes mellitus, but in severe cases no clinical argument could support it; indeed, experimental pancreatic diabetes contradicted it. The burning up metamorphosis seems to have more clinical support than ever. At this point Freund reminded Falta that Külz founded the whole of his chemical theory of diabetes on purely clinical evidence, and not on laboratory experiments like these of Loewi's.

Loewi replied that his experiments with the stimulation and inhibition of the different fibres of the sympathetic were not stimulation and inhibition of the vascular nerves nor on the consumption or expenditure of oxidisable material, but rather a physiological function in the nerve system existing between this and the spleen. His theory is purely experimental, although, curiously enough, the 28 cases given above support the theory in the sugar metamorphosis.

Injury to Neck With Paralysis.

Heyrovsky presented a case of some interest from its subsequent development. The patient was æt. 62, and in January, 1906, received a stab in the left posterior side of the neck. The external jugular vein was slit open for some distance, but beyond that no other untoward circumstance was present.

The wound healed kindly in a very short time, but suddenly one day an unusual sequence was discovered in paralysis of the left recurrent nerve from a probable injury of the left vagus which appears to have involved the left sympathetic as myosis and enophthalmos were present. On closer investigation it was ascertained that the myositos and enophthalmus or contraction of the pupil and retraction of the eye-ball were noted immediately after the accident, but it was expected they would recover on the wound healing; but instead of disappearing they have become more accentuated.

The question arises concerning the real site of the lesion. Injury to the recurrens or vagus will affect the vocal cords as it has done in this case, but the sympathetic is also involved. The respiratory signs and frequency of pulse are absent, which usually accompany injury to the vagus, but the paralysis of the left vocal cord is present, which would indicate that the recurrens and sympathetic alone are injured.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

THREE TERM SESSION IN EDINBURGH UNIVERSITY.

The King in Council has approved a new ordinance which will effect very important changes on the Edinburgh medical curriculum. The question of a three term session, with corresponding alteration of the dates and sequence of the professional examination has been under the consideration of the various governing bodies of the Association for some years back. The originator of the reform, which has now been accomplished, was Professor R. J. A. Perry, now of Melbourne, and the new arrangement will, it is believed, lighten the burden of the student by enabling him to take his classes and examinations in a more convenient order, and will not lessen his work, but allow of its being expended with more profit to himself. The ordinance has been delayed through the opposition of the Universities of Glasgow and Aberdeen; the tradition has been that all the universities toe the line together, and the pace of progress is that of the most conservative and slow moving. Even were the ordinance in itself trivial, it would be important in the earliest step towards autonomy on the part of any one university, for it is the first ordinance in which one university has struck out a line of its own, and has not waited for conjoint action with its fellows.

The new arrangement will remove one anomaly, namely, that materia medica will no longer be studied before pathology, and then the student will know something of disease before he comes to its remedy. An outstanding feature is the division of the winter session into two half sessions—October to Christmas and January to March. Professional examinations will now be held thrice yearly—December, March, July, at the end of each term. At present there is no professional examination at the end of the second year, consequently slackness is engendered among the students, and the third year is burdened by arrears. Now an examination in physiology is provided at the end of the second year. In order to leave more time for clinical and practical work the examination in anatomy may be taken three months earlier than before. The examinations in materia medica and pathology have been transposed, so that the latter now precedes the former. The final examination may now be taken in four parts. Forensic medicine and public health may be taken at the end of the summer session preceding the final winter, and midwifery at the following Christmas. In March, at the end of the final year, systematic medicine and surgery can be taken, and clinical medicine and surgery in the summer thereafter. The present final drags a weary course of two months, all subjects being taken at once, this involving about eighteen separate appearances for examination. Being now allowed to distribute his work over a larger period greater proficiency and a higher standard should be attained and ought to be exacted. The new regulations will apply to all students, future and present, and take effect in October.

TYPHOID FEVER AT PETERHEAD.

A somewhat extensive epidemic of typhoid fever fortunately of a mild type, has been in full swing in Peterhead for the past month, during which period nearly 200 cases have been notified. The source of infection has been found in one of the reservoirs, the water of which has accordingly been cut off. In the herring season especially, this deprivation of part of the usual water supply has been greatly felt, and the Government authorities are helping the town as much as possible from their special supply used for the convict prison, having placed at their disposal between 30,000 and 40,000 gallons per day. The epidemic was at first thought to be connected with the milk supply, but Dr. Dittmar found that it was too extensive to be accounted for by this, and traced it to the water. He states that a purer and larger water supply is required by the town, which has outgrown the present sources. The present springs require protection from pollution, and stream and surface water should be excluded. Since the epidemic began there have been 216 cases with only 12 deaths. Fortunately for the prosperity of the town, the population of which has swollen from 13,000 to 18,000 during the fishing period, this industry has not been interfered with by the epidemic, and no strangers have been among the patients. A fresh water supply has been under consideration for some years, and a scheme is now being adjusted which will give the town an abundant supply for the next quarter of a century at a cost of about £10,000.

BELFAST.

Bangor Nursing Society.—The annual meeting of the Bangor (Co. Down) District Nursing Society was held last week, the president of the Society, the Dowager Marchioness of Dufferin and Ava, in the chair. In recounting the year's work the president said that their nurses had had 260 cases under their care, and had paid 5,645 visits. The Society had also given help in the form of food and clothing to many necessitous cases. Professor Sinclair, F.R.C.S., moved the adoption of the report. After speaking of the need of such societies as this, and the amount of human misery which they relieved, he dealt at some length with the subjects of infantile mortality, medical inspection of school children, and the physical degeneration of the race. He pointed out that in dealing with all these important problems the district nurse had a part in the work. Lady Helen Munro-Ferguson also spoke, and told the ladies present "that while they looked after the work of their Society among the poor, it was also their duty to see that their nurses were properly remunerated, had provision made not only for the present, but also for the wants of old age, did their work under the best conditions, and had that recreation and change which ensured the maintenance of their good health and, what was equally necessary to that success, their good spirits."

Up to August 14th, 132 cases of cholera were reported to have occurred in Samara, 36 of them ending fatally. Twenty-five cases and six deaths occurred in Astrakhan. Two deaths from cholera are reported from Yaroslavl.

LETTERS TO THE EDITOR.

MILK AND TUBERCULOSIS.

To the Editor of The Medical Press and Circular.

Sir,—I have yielded to the suggestion of "A Family Doctor," and I have very carefully read (but not without some impatience at the absence of *facts*) this paper to which he refers me. From the beginning to the end I do not find a single *fact* that can be regarded as *evidence* in support of the view of the writer. It is all pure assumption, and the following sentences condemn his views beyond the hope of reprieve: "This disease (tuberculosis) is insidious in its approach; its period of incubation is unknown; the signs of its presence are for a considerable time indistinguishable from those of other ailments; and the means of tracing its probably remote origin *are not available. Hence the impossibility in the present state of our knowledge of presenting evidence of the extent to which the disease may be attributed to milk* or any other individual cause." I endorse his quotation, viz., "If there be anything like the danger from the meat and milk of tuberculous cattle that medical officers of health say there is, we should all have been dead of tuberculosis long ago."

In spite of what the writer of the paper says, viz., "That the cowhouses in the rural districts are as insanitary as ever," and of all the causes that are at work in the production of this disease, it is an incontestable fact that the disease is becoming less prevalent under the improved conditions of life at present existing.

If, then, I fail to find anything in the paper with the slightest pretence to evidence, and the advocates of the theory involved fail to produce one solitary instance in which there was even a suspicion that the disease had been communicated to a human subject by means of milk, I must continue to hold my present views in which I feel myself fully justified, and I am not in a position to confess that they can no longer be maintained."

"A Family Doctor" appears to accept statements that are not supported by any evidence. I am not in that frame of mind.

I am, Sir, yours truly,
George Granville Bantock.

August 17th, 1907.

THE NEW ADVANCE AT THE INTERNATIONAL CONGRESS OF SCHOOL HYGIENE.

To the Editor of The Medical Press and Circular.

Sir.—As a slightly incorrect statement has been published it would be as well to explain in some detail the important new move in the matter of School Hygiene which was taken at the closing meeting of the recent International Congress. The permanent International Committee consisting of about sixty members selected from almost every country has hitherto only met during Congresses. Arising out of the question of whether it would not be a proper thing to establish a Bureau, with a permanent staff, library and museum, and so on, in some central but neutral spot, such as a Swiss or Dutch town, it was decided, as explained by Drs. Mathieu, Burgerstein and Kerr, that it would probably lead to greater progress if such Bureau was not localized, but if each country had its own centre for the diffusion of knowledge, and to act as a clearing house in the matter of School Hygiene statistics laws and regulations. Finally, to supervise in scientific matters and generally to do all that is possible at all times or places to forward the human interests which are bound up in the special lines of knowledge included in School Hygiene, the International Committee has formed a small Council.

This Council has all the powers of an ordinary Committee. It can form sub-committees of experts on special enquiries. The usual Committee procedure is to sit round a table and discuss matters, but this Council will deal with the various subjects that arise, submitting the different topics by correspondence.

collating the answers, and, finally, making pronouncements in urgent matters after a meeting of the Council.

It is obvious that for efficiency such Council should be small and yet have in the elements to secure permanence, and, at the same time, possibilities of slow but constant change. This has been done by deciding that it shall consist of the president of the past Congress, the president of the Congress which has just been held, and the president of the next Congress. Nine other members are to be elected, of whom three are to be from the country where the Congress was last held, and three from the country where it will be held next, three being selected from other lands.

Certain matters for instance will almost at once come under the consideration of this Council. Such might be quoted as:—

"The question of how medical inspection of schools can best be carried out with the maximum of efficiency and minimum of cost."

"The question of how far the laws of health can best be imparted to the coming generation, so that later they will know how to care for themselves and those dependent on them."

"The best systems or methods of physical training for both sexes at various ages."

"The feeding of children requiring proper nutrition, so that it shall be done without developing pauperism and with regard to those upon whom the cost falls."

These four matters are being dealt with practically in a great variety of ways, and this Council should be able to collect and analyse known facts to show which methods are best for any town or State.

It is obvious that information thus digested will have a very great value politically as well as educationally, and this Council may in time come to be officially regarded as quite analogous in matters of School Hygiene, to that other Congress of Peace now in session at the Hague.

I am, Sir, yours truly,
Lauder Brunton, President.
E. White Wallis,
James Kerr,
Hon. Gen. Secs.

QUACKERY IN DRUGS.

To the Editor of The Medical Press and Circular.

Sir,—One of the best plans of scotching the quack medicine trade would be for all retail chemists to write and refuse point blank to stock such articles, and in addition, if all medical men would begin again to write prescriptions, as in the past, the difference would soon be felt, if only by the inconvenience experienced in endeavouring to obtain the articles so largely advertised by those who will not pay a doctor, but prefer self-medication. The gain eventually to both retail chemists and medical men themselves would certainly be appreciated.

I am, Sir, yours truly,
Alexander Duke.

London, W.

P.S.—The curse of the nation is self medication.

OBITUARY.

W. H. BROWN, M.Sc., F.R.C.S.I.

We regret to announce the death of Dr. W. H. Brown, the well-known Leeds surgeon, which took place at Headingley, Leeds, on August 15th. Two years ago, while performing an operation, Dr. Brown contracted blood poisoning, and up to the time of his death he never succeeded in completely throwing off the effects of that illness. For some time past his condition has been serious, and the announcement of his death was not unexpected by his friends.

Dr. Brown spent practically the whole of his life in Leeds. He received his early training at the Leeds Grammar School, and subsequently studied medicine at the Leeds School of Medicine. He obtained his M.R.C.S. (England) degree in 1878, and almost continuously from that time to his death Dr. Brown was connected with the Leeds General Infirmary. After filling the position of resident house surgeon he was appointed resident surgical officer. In the year 1884 he became hon. assistant surgeon, which office he held until 1890. In that year he was appointed to the full staff, fulfilling his duties until his resignation in December, 1906, on account of ill-health. He was then appointed hon. consulting surgeon. On his retirement the Weekly Board placed on record their high appreciation of the great services Dr. Brown had rendered to the institution. Dr. Brown for some time was house surgeon at the West London Hospital. He was also a demonstrator of anatomy at the Yorkshire College—now the Leeds University—subsequently being lecturer in clinical surgery. He became a Fellow of the Royal College of Surgeons, Ireland, in 1887, and M.Sc. (Leeds) in 1905. He was a medical referee under the Workmen's Compensation Act, and late hon. surgeon to the Leeds Public Dispensary. In March of 1905 Dr. Brown called the attention of medical men and the public to the dangers of the primula obconica, as illustrated by the death of a Leeds lady who, when recovering from an attack of influenza, accidently scratched her nose while smelling the flower, death ensuing within a week.

Dr. Brown was an ardent supporter of the Leeds Choral Union. From its inauguration he took a keen interest in the work of the society, having occupied the position of president. At the time of his death he was a vice-president of the union. Although taking little part in the public affairs of the city, Mr. Brown was a well-known figure. A man of striking personality and genial presence, he made many friends during his professional career, and his death will be mourned by all who knew him.

MALCOLM L. MARGRAVE, M.R.C.S., L.R.C.P.

We regret to announce the death from morphia-poisoning of Dr. M. L. Margrave. The news of his tragic death aroused deep sympathy in his native town of Llanelly, where he and his family are held in high esteem. The deceased gentleman was the youngest son of Mr. Robert Margrave, J.P. He was educated at Llandovery College, and thence proceeded to Edinburgh. He received his medical education at St. Bartholomew's Hospital, London. After acquiring his diplomas of M.R.C.S. and L.R.C.P. (London), he held the posts of house physician and house surgeon at the West London Hospital. After holding many and various appointments in private work, he travelled abroad, and for some time acted as surgeon in the service of the British India Steam Navigation Company, in which capacity he made several voyages to the East. He eventually settled down at Newton Abbott in partnership, and it was here that his health broke down. Later on serious heart mischief made its appearance, and it became imperative that he should seek a more bracing climate to live in. He was advised to remove to Scotland, and less than twelve months ago he went into practice at Moffat.

Apart from his purely professional attainments, Dr. Margrave was a man of wide culture and versatile talents. He was one of the finest tennis players in West Wales, and as an athlete generally he excelled. He was also a great reader, his knowledge of English literature being extensive.

CHARLES WILLIAMS, M.R.C.S., F.R.C.S.Edin.

We regret to announce the death of Dr. Charles Williams, M.R.C.S., F.R.C.S.Edin., who had for many years practised in Norwich, and at the time of his death was senior surgeon to the Norfolk and Norwich Hospital. Dr. Williams received his training at the infirmary in that city and at Charing-cross Hospital. He had an extensive private practice, and was consulting surgeon to the Norfolk and Norwich asylums. Dr. Williams was an authority on the life and writings of Sir Thomas Browne. He possessed a fine collection of early editions of Browne's works, and was the author of pamphlets on "The Measurement of the Skull of Sir Thomas Browne," "The Portraits of Sir Thomas Browne," "The Bibliography of the Religio Medici," and "The Pedigree of Sir Thomas Browne." He also published interesting facts about "The Treatment of the Sick in Norwich during the 17th century," and "The Barber Surgeons, of Norwich."

SPECIAL ARTICLE.

THE REPORT OF THE LOCAL GOVERNMENT BOARD FOR IRELAND FOR 1906-7.

Tuberculosis in Ireland.

The Annual Report of the Local Government Board, which has just been issued, supports very fully the opinion put forward by the Registrar-General with regard to the prevalence of tuberculosis in Ireland.

The present report dwells on the fact that in 1905 close on 12000 deaths in Ireland were due to tuberculous diseases, and particularly to pulmonary tuberculosis and that the death rate from this particular form of disease stands at a far higher figure in Ireland than in either England or Scotland. Referring to the feeling that has been aroused on the subject, the Local Government Board say that they are glad to state that the question has aroused very general interest, and that some of the sanitary authorities in and about Dublin, where the death-rate from tuberculosis is especially heavy, are taking steps to combine in a scheme for the establishment of a joint sanatorium for consumptives.

The Board fully recognise, they say, that it is a tedious and difficult task to secure co-operation among sanitary authorities for the establishment of sanatoria. The cost is for the most part too great to admit of one authority undertaking the erection of a sanatorium single-handed, and consequently a united district and a joint board of several authorities has to be constituted by Provisional Order, involving delay and considerable trouble in securing the consent of the various local bodies affected. On this point by way of a solution of the difficulty, the Local, Government Board say:—

"If the matter remains in the hands of existing sanitary authorities, a long period is likely to elapse before there is proper accommodation for the treatment of consumptives throughout Ireland. We consider, however, that many of the difficulties at present experienced would be overcome if power were given to County Councils to establish and maintain, either singly or in combination, suitable institutions for the treatment of consumptives."

The Board state further that in the opinion of their medical department the prevention of consumption should be dealt with on a systematic plan, consisting of these four elements:—

(1) Advanced cases should be accommodated apart in hospitals, the mere segregation of highly infectious patients from healthy persons being in itself a great safeguard against the spread of the disease.

(2) Where the disease is in an incipient stage and is capable of being cured or arrested, sanatoriums should be provided, where persons affected could be sent for proper treatment.

(3) In large centres of population, dispensaries where advice can be obtained, and where the latest methods of treatment can be tried, have proved very successful in other countries, especially in France, and might be established in Ireland with advantage.

(4) Lastly, local committees appointed by sanitary authorities to deal with the question of consumption would be very beneficial. The functions of such committees would be educative. They should endeavour to personally convey information to sufferers and also circulate leaflets and literature relating to this disease. Much might be done by active committees, who would advise their neighbours on the advantage of simple sanitary precautions in their homes.

Something more even than this, however, is needed in the opinion of the Local Government Board. They say, specifically:—

"We are of opinion that compulsory notification of pulmonary tuberculosis should be carried out by special legislation, and that safeguards should be provided to ensure that no unnecessary restraint is placed on the liberty of consumptive patients. If notification is used merely for the purpose of gaining information as to the locality of the disease, and helping the sufferer by giving assistance and advice, which would be useful in protecting other members of his family from contracting the disease, we consider that it would, under efficient and sympathetic administration, be a most useful public health measure."

The Board report that the Guardians of the South Dublin and Belfast Unions have shown a keen desire to improve and enlarge their accommodation for cases of consumption. The former, we are told, are making an extension of their female consumptive department for twenty additional patients. The Belfast Guardians it appears, have, during the past year, opened four pavilions at the Abbey Sanatorium, in which there were 112 patients on March 31st last, and the large hospital, which is rapidly approaching completion, will accommodate about 150 of the less hopeful cases. With the completion of this building, the Guardians will have spent about £34,000 on the purchase of the site and the erection of the buildings. The sanatorium will then have accommodation for about 265 patients with space for further extensions, which, however, will cost considerably less per bed, as the ground and the administrative arrangements are already provided.

Speaking generally of the country, the Board say that the subject of the treatment and segregation of cases of pulmonary tuberculosis in workhouse infirmaries continues to receive constant attention, and the nature of the disease being now more fully recognised, Boards of Guardians are evincing greater willingness to make provision for the care of patients suffering from it.

NEW PREPARATIONS.

ROGERS' MUSCATOL IN INSECT BITES.

Under the title of "Muscatol" Mr. Frank Rogers, the well-known chemist of Oxford Street, London, has introduced a pleasant preventive of insect bites. There is plenty of room for a good preparation of the kind, and Muscatol, so far as we have been able to judge, fulfils its purpose in a safe and efficient way. Who that has travelled would not often have given almost anything in his possession for a boon of this kind? Imagine what it would be to be able to defy the mosquitoes, say, when lying in harbour in Singapore, or in a West Indian port? Beyond the mere annoyance of mosquito bites there is, of course, the far more serious point of the malaria that is conveyed in that way. In future, however, the traveller or the sportsman can carry about with him protection in the shape of one of Mr. Rogers' bottles of Muscatol, sold at prices varying from a shilling to a guinea. It can be applied by a dropper or by a convenient little spray, and may be applied to clothing, bedclothes, or the skin-surface, generally or locally. If Mr. Rogers, by his timely remedy, can protect the patient fisherman at home and abroad, and the equally patient artist, from the bites of gnats and other noxious flies, he will be entitled the enduring gratitude of a great many of his fellow beings in all parts of the world.

BURROUGHS WELLCOME'S TABLOID "GINGA-MINT." (Soda Mint Compound.)

This new preparation of Messrs. Burroughs Wellcome, claims to be a valuable antacid and stomachic for the relief of dyspepsia, nausea, heartburn, and flatulence. It is said to promote appetite and digestion, while at the same time it relieves griping and produces a diffusible stimulant effect. The composition is as follows: Each contains sodium bicarbonate, gr. 5; ammonium bicarbonate, gr. 1-12; with gingerine, saccharine, and oil of peppermint.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

***Specially compiled for* THE MEDICAL PRESS AND CIRCULAR.**

RECENT SURGICAL LITERATURE.

The Treatment of Detachment of the Retina.—Professor Deutschmann (*Ophthalmoscope*, July, 1907) advises that operative treatment for detachment of the retina should be resorted to earlier than is usual, as much time is wasted in pacific treatment which gives such bad results. Prof. Deutschmann considers that his operative treatment gives better results than such procedures as (1) simple scleral or sclero-chorioidal puncture, or puncture of sclera with a galvano-cautery; (2) puncture of detached retina; (3) permanent drainage; (4) electrolysis; (5) intra-ocular injection of iodine; (6) cauterisation of sclera with or without sub-conjunctival injection of sodium chloride solutions. The author's operations are two in number. One he calls "bisection," the other consists of the injection of sterile animal vitreous body into the diseased eye. In performing the bisection operation, a double-edged knife is inserted tangentially to the globe downwards and outwards, passed horizontally across, making the counter puncture directly opposite, *i.e.*, downwards and inwards. The counter-puncture involves the sclera only, the conjunctiva being spared. In withdrawing the knife it is given a half-turn, which allows the sub-retinal fluid to escape. The eye is atropinised, and both eyes are bandaged for twenty-four hours, the patient being kept in bed seven or eight days. If necessary, the operation may be repeated in ten to fourteen days, and be done as often as ten or twenty times. The operation may be considered to be devoid of danger. The mischances one has to consider are the wounding of a large retinal vessel, or the lighting up of a previously existing inflammatory process. The injection of animal vitreous appears to be reserved for desperate cases, and need not be related here. M.

Scoliosis: Its Prevention and Treatment.—M'Ilhenny (*Lancet-Clinic*, July 20th, 1907) divides scoliosis into postural and structural. He believes that rickets holds a more important position in the ætiology of scoliosis than is generally conceded to it. The family physician is the person on whom the responsibility of preventing this condition rests, for it is he who has the opportunity to recognise deformities in their incipiency. The fundamental points in treatment are two: First, to correct the deformity and limber up the vertebral column as much as possible; and, second, to develop the muscles of the back so that they may be able to support the spine in the proper position. In the treatment of postural scoliosis, where no changes have taken place in the bones or soft parts, it is merely necessary to correct the faulty position and build up the weakened muscular system with massage and gymnastics without the aid of corsets or braces. Every case is first treated with hyperæmia. The patient sits with the back to a pentagonal cabinet which has an opening, oval in shape, cut in each side just large enough to allow the bared back to fit into it from about the sixth cervical to the fifth lumbar vertebra, and about three inches on each side of the spinous processes. In the centre of the cabinet there is a gas burner. The temperature is raised from 120° to 230° F., and the application lasts from fifteen to twenty minutes. After the patients have had the hot air application and their backs massaged for ten to fifteen minutes, they are then put through a course of simple gymnastics for half an hour. The less complicated the exercises are the better. The main point is to educate the body to involuntarily maintain the proper position. The treatment of structural scoliosis is more difficult as changes in bones, muscles, and ligaments have taken place, and motion is limited. While obtaining as much extension as possible in an extension frame, a plaster-of-Paris corset is applied. No padding is used, and the corset is well moulded over the hips and shoulders, the latter being incorporated. When the plaster sets the corset is cut down in front, removed and trimmed. When reapplied, it is laced up in front over shoe-hooks with elastic lacings, which causes constant pressure laterally. The author places a thin pneumatic cushion under the corset posteriorly, and one over the anterior opposite projection. By so doing the pressure on these parts is increased, and there is a tendency to untwist the rotation, besides correcting the lateral displacement. After the corset is finished the patient has a daily application of hyperæmia for twenty minutes, and then goes through the exercises. The first and most important exercise is a form of crawling on the floor, which is described in detail. The benefit of this exercise depends on the fact that when the limbs on one side of the body are well approximated in crawling, the spine becomes well bent with its convexity in the opposite direction. After the exercises the patient rests for twenty minutes in a correcting frame devised by the author. The corset is worn night and day for six weeks, being only removed for exercises and hygienic reasons. Fresh corsets are made about every two months with the patient in the best corrected position. These are used only during the day. It is a great mistake to keep a brace or corset on too long, for the muscles after a time rely on the artificial support, and atrophy consequently sets in. S.

Inoperable Sarcoma.—Coley (*Medical Record*, July 27th, 1907) makes a further report of cases successfully treated with the mixed toxins of erysipelas and bacillus prodigiosus. The author has himself successfully treated 42 cases, and 60 cases have likewise been successfully treated by other medical men. Of his 42 cases, 17 were round-celled sarcoma, 17, spindle-celled sarcoma, 2 mixed-celled sarcoma, 1 chondro-sarcoma, 1 epithelioma. In 4 no microscopic examination was made; yet the clinical features of the cases, such as recurrence after operation, rapidity of growth, size, and inoperability of the tumours, left hardly any doubt as to the diagnosis. The late results in these cases are as follows:—21 well from 5 to 14 years, 26 well from 3 to 14 years, 10 well from 10 to 14 years. Twelve cases are reported in detail. Coley finds that Dr. Tracy's method of preparing and standardising the toxin is the most satisfactory. It consists of: Streptococcus culture in broth, three weeks' growth 100 c.c. Prodigiosus suspension, containing 750 milligrams of prodigiosus proteid, 30 c.c. (sterilized one hour at 75°), glycerine, 20 c.c. After mixing and bottling the toxines the mixture is again sterilized two hours at 75°. One minim contains about 3 mgrs. of prodigiosus. It is most important in every case to begin with a very small dose, not over ¼ minim (diluted with a little boiled water to ensure accuracy of dosage). If the tumour in question is highly vascular it is wiser to begin the injections remote from the same, until the susceptibility of the patient to the toxins has been ascertained. As a rule, when giving injections into the tumour, only about one-fifth of the dose used for injections remote from the tumour is required to produce the same reaction. The best results are obtained by doses sufficiently large to produce severe reaction, say a temperature from 102° to 105°. The frequency of injection must depend entirely upon the strength of the patient, some being able to bear daily injections, while in others it may be unwise to push the treatment beyond three or four injections a week. In successful cases the effect is usually very promptly noticeable. The tumour becomes smaller in size, much more movable, and very much less vascular. These changes appear quickly, often within two or three days. The action of the toxins is both local and systemic. Sometimes the best results are obtained by giving injections alternately into the tumour and remote from the same. In intra-abdominal sarcoma, &c., a perfect cure may be obtained by systematic injections entirely.

S.

Partial Perforation of the Bowel Simulating Appendicitis.—P. Blumer records a case (*Lancet*, July 20th, 1907) of a coal worker, who, while pushing a heavy object with his foot, felt something give way inside himself, but for several hours felt no pain, then severe pain began in the right iliac fossa, the bowels acted, and the desire to pass water became very urgent, his temperature and pulse rate at this time were normal. On his admission to the infirmary a few hours later, he presented all the appearances of a man with an acute attack of appendicitis, temperature now being 102, and pulse about 80, he had no history of any previous attack of a similar nature. The pulse soon afterwards rising in frequency to 104, the abdomen was opened, and in the midst of a good deal of inflammatory lymph about the cæcum, a small tear of the muscular and serous coats of this organ was found. The lesion was about two inches from the butt of the appendix, and through the rent the inner coat was bulging out. The walls of the bowel were closed and the patient made a complete recovery. On account of the slight violence which caused the rupture of the bowel, and the close manner in which it simulated appendicitis, the case possesses considerable interest. G.

The Treatment of Suppurative Pyelitis by Lavage of the Renal Pelvis.—W. Ayeres gives an account of six cases (*International Jour. Surg.*, May, 1907) of pyelitis, which he had treated by local applications to the renal pelvis; in all the cases the infecting cause was the gonococcus. When no real kidney substance was felt, only slight improvement occurred, but when the suppurative process had only affected the kidney itself, to a small extent, rapid improvement or recovery followed. The solutions employed were argyrol and silver nitrate, the latter used at a strength of about 1 in 7,000, the ureter being catheterized through a cystoscope in the usual manner. Of these six cases two were failures, and nephrectomy had later on to be done, the remaining four were satisfactory, one being much improved and the other three completely cured. In one of these cases the flushing out of the pelvis of the kidney had only been done four times when all pus ceased coming from the ureter. In this case gonococci, although suspected, were not actually found, and this may account for the rapid cure.

G.

Renal Calculus: Its Etiology and Treatment.—P. Horowitz (*Post Graduate*, July, 1907), in a paper, illustrated by numerous cases, on this subject, deals very fully with the over-production of uric acid, drawing the following conclusions: 1. Renal calculus is the result of faulty metabolism. 2. The uric acid type, is the most common form. 3. The action of the calculus on the genito-urinary tract is purely mechanical. 4. Small loose stones in the pelvis and ureter cause the most symptoms. 5. There are cases of a single large stone occupying the pelvis and calices of the kidney without any symptom. 6. The most important symptoms are, pain, colicky in nature, starting in the region of the kidney or the loins, radiating down the ureter to the bladder and thigh, and to the penis and testicle in the male, and to the labia in the female. Hæmorrhage, beginning usually with the passage of the stone into the bladder, may be slight or excessive. Frequency of micturition, or occasionally calculous anuria. 7. The diagnosis is often uncertain unless the stone can be palpated, or be shown to be present by the X-rays. 8. Indican is an index to the condition of the digestion, therefore, pointing out the possibility of an existing suboxidation, and therefore the possibility of this condition being present also. 9. The Paquelin cautery is a valuable aid for relieving the congestion of the kidney, and thus aids in breaking up an existing anuria. 10. Carbolic acid stops the pain of renal calculus very quickly, and prevents recurrence by changing the over-produced uric acid into urate of sodium. 11. Attention to diet is of great importance in the treatment of renal calculus. Fruits must be excluded. G.

A Cause of Podalgia.—F. Bird, in an article illustrated by X-ray photographs (*Intercolonial Jour.*, June, 1907), gives an interesting account of four cases of podalgia, all of which had been treated by the ordinary methods without success, two of the cases were believed to be gout, yet on taking X-ray photographs of the os calcis in each case a spur-like process of bone was found growing from the under surface of that bone, the spur growing forward and running parallel with the sole of the foot; in one of the cases a similar process was found going on at the insertion of the tendo-Achillis. The author suggests that the condition present in these cases is a slowly progressing osteo-periostitis. There is no clear connection between these cases and cases of inflammation of the plantar fascia. In each case the same treatment was adopted, an incision made parallel to the sole of foot was carried down to the calcaneal tuberosity, the position of the bony spike having been determined by the finger a gouge was introduced and the offending portion of bone removed, the wound closed without drainage, the patient only kept in bed for three or four days. In all the cases the relief from pain was immediate, and has, up to the present, been permanent. G.

Rhinoplasty by Means of One of the Fingers.—Finney (*Surgery, Gynæcology, and Obstetrics*, July, 1907) describes the operation which he has performed successfully in two cases as follows: The ring finger of the left hand is selected. The nail and matrix are completely removed, the dorsum of the finger up to the distal end of the first phalanx denuded of skin. The top of the finger, throughout its entire circumference, is also denuded of skin for about the distance of 1 cm. from the end, leaving the distal phalanx exposed, but not completely so. The skin covering the nose which is retracted and deformed owing to cicatricial contractions, is then freed carefully from its attachments below without making any external scar. The skin of the nose is then stretched carefully and thoroughly. The soft parts are next freed from the nasal process of the frontal bone. The inner surface of the skin forming the nasal covering should be denuded on the inner side of the middle line, in order that a raw surface may be opposed to the denuded surface of the dorsum of the finger, which is now inserted into the nasal opening, until the tip of the distal phalanx rests upon the nasal process of the frontal bone. The finger is held in place by suture through the free border of the tip of the nose and the edge of the skin over the dorsum of the first phalanx. The hand is held in this position for two weeks, after which time the finger is disarticulated at the metacarpo-phalangeal joint and left for another week; at the end of this time the tissues over the nasal spine of the superior maxilla are split, and the finger flexed to a right angle at its proximal-phalangeal joint. The free end of the first phalanx is inserted into this opening and held there by stitches through the soft parts. The first phalanx forms the columna of the nose, while the second and third phalanges form a very satisfactory support for the dorsum. Later, smaller operations, under cocaine, are performed to improve the appearance of the columna. It is well as a preliminary operation to stiffen the last phalangeal joint of the finger in order to prevent a slight tendency to sagging of the bridge of the nose. S.

Medical News in Brief.

The King and India.

The India Office has issued the following letter which His Majesty the King has addressed to the Governor-General of India:—

Buckingham Palace, August 13th, 1907.

"My Dear Viceroy,—I have followed with anxious interest the later course of that epidemic of plague by which India has for eleven years past been so sorely afflicted.

"The welfare of my Indian subjects must ever be to me an object of high concern, and I am deeply moved when I think of the misery that has been borne with such silent patience in all those stricken homes.

"I am well aware how unremitting have been the efforts of your Excellency's predecessors and yourself to make out the causes of the pestilence and to mitigate its effects.

"It is my earnest hope and prayer that the further measures now being prepared by your Excellency in consultation with zealous and able officers, may be crowned with merciful success.

"I desire you to communicate this expression of my heartfelt sympathy to my Indian subjects.

"Believe me, my dear Viceroy, sincerely yours,
(Signed) Edward R. and I."

Progress of the Plague Measures.

A Reuter's telegram from Simla states that a Gazette Extraordinary has been published there, containing the above letter, and also a letter from the Viceroy to the local Governments and one from the Indian Government. The Earl of Minto states that the difficulties in the way of eradicating the plague are enormous, chiefly owing to the inability of the people to understand sanitary and hygienic measures.

In the third letter the Government of India states that the Plague Commission believed, first, that the bubonic plague is spread by rats; secondly, that the vehicle of contagion is the rat flea; and thirdly, that the life of the plague germ in soil, floors, and walls is of short duration. The Government recommend the destruction of rats, the improvement of the construction of houses, the reduction of the food supplies of rats by the protection of grain stores, the removal of people to temporary dwellings, and inoculation, while avoiding any action calculated to excite the opposition of the people.

Annual Dinner of the Caledonian Medical Society.

This Society met on August 1st in Bradford, under the presidency of Dr. Andrew Little, of that town. There was a good attendance from far and near. The membership, which consists of Highlanders, University medical graduates, now numbers 240, and they are spread all over the world. The great majority are graduates of Edinburgh. Glasgow and Aberdeen, in almost equal numbers, together furnish about half the membership, and there are a few from Oxford, Cambridge, and St. Andrews, and from the Royal University of Ireland.

The meeting took place at the Royal Eye Hospital, an extremely handsome and convenient building, of which Dr. Little is surgeon, and of which another Scot, Dr. John Bell, was founder. The latter it was who first declared that the "wool-sorters' disease" was due to a living germ, and made several valuable suggestions for its prevention, which were subsequently embodied in Acts of Parliament. He was also the pioneer of operation upon the eye for cataract and other diseases.

Sympathetic reference was made in the secretary's report to the deaths within the last few months of Dr. Alexander Macbain and the Rev. John Watson ("Ian MacLaren.")

The Dinner.

At the dinner in the evening at the Midland Hotel there was a large gathering of members and guests. The President proposed the loyal toasts. The toast of "The Caledonian Medical Society" was proposed by Dr. Swanson, of York, and responded to by Dr. S. R. MacPhail, of Derby; "The Universities," by Sir William Sinclair, of Manchester, and responded to by Dr. MacKenzie, of Burnley; "Caledonia," by Dr. Rabagliatti, of Bradford, who claims his Highland right because he is married to a daughter of the late Mr. Bright MacLaren, the well-known Member of Parliament.

Among other members present were:—Drs. Mackintosh, Stirling; MacGregor Sinclair, Burnley; Menzies, Mitchell, Dunlop, Munro, Clow, Beatton, Bonar, Gray, Hall, Baldwin, Dunlop—all of Bradford; Dr. MacGregor (a son of the late "Alastair Ruadh" of Inverness); Dr. MacNaughton, Stonehaven; Dr. Cameron Gillies, London; Dr. Stewart, Bacup; Dr. Blair, Lancaster; Dr. Bonner, Shipley; Dr. Angus, Bingley; Dr. Gordon Little, Blundellsands; Dr. Logan, Harrogate; Dr. Gairdner, Burnley; and quite a number of friends as guests.

The dinner was done in thoroughly good Highland form. There was a gorgeous piper, in the full Stewart dress of the old time. There was haggis and other things, and hearty good-fellowship.

Dr. Dunlop invited the members to his house, and among the relics exhibited was half a banner of the Clan Fraser that was at Culloden. The following is the history of this banner:—

"The complete colours were given to a Dr. Mackintosh, of Inverness, a great antiquarian, by the then Fraser of Lovat. In 1827 Dr. Mackintosh divided the colours into two parts—one he kept himself, and the other part, the history of which is now being traced, he gave to Mary Stewart, spouse to Dr. MacLaurin, of Culloden, Inverness, and afterwards of Bradford, Yorks. Mrs. MacLaurin died in 185-, bequeathing the colours to her daughter, Mary Miller, spouse to Jonathan Beattie, in 1883. The colours passed into the possession of their daughter, Agnes Paterson, spouse to John Dunlop, M.D., of Bradford.—(Signed), Agnes Paterson Dunlop.

"May 20th, 1883."

The motto of the clan is given in English, "I am ready," but only the letters "I am re—" are on this half. It would be interesting to know if the other half of the banner is in existence.

Presentation to a Medical Man

The guardians and officials of the Willesden Union have presented to their medical officer, Dr. Walter E. Turner, a handsome cabinet of table cutlery and fish carvers on the occasion of his marriage to Miss Jessie Powell, of Tregaron, Cardigan. Some of the inmates of the workhouse also presented the doctor with a beautifully-worked drawn-thread teacloth.

School of Tropical Medicine—Further Grant.

In the House of Commons on August 15th, Colonel Seely asked the Under Secretary for the Colonies whether, in view of the work already accomplished by the Liverpool School of Tropical Medicine in combating tropical diseases, he could arrange for an increased grant to be made in order that the work may be further extended. Mr. Churchill said a further grant will be made, of which the Secretary of State will be able to specify the amount after consultation with the Treasury.

NOTICES TO CORRESPONDENTS, &c.

☛ **Correspondents** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessary for publication but as evidence of identity.

Dr. A. D.—The newspaper paragraph to which you draw attention is an advertisement in the worst possible taste. and for this reason cannot have been connived at by the physician mentioned therein. In all probability it is one of those unfortunate instances of journalistic irresponsibility, to which members of our profession are peculiarly subject.

G. W. M.—Your communication came to hand as we were "at press"; it will be duly considered before our next issue.

Docks.—It is a common mistake to attribute to Manson the original theory that the organism of malaria passed through the mosquito as its intermediate host. As a matter of fact, Laveran, who discovered the organism in 1880, formulated the theory of mosquito transference in 1884. But Sir Patrick Manson did more than anyone to keep the theory in being till its truth was demonstrated by Ross.

STATISTICS OF INDUSTRIAL POISONING.

Alien.—Regular returns are made monthly by the Home Office as to industrial poisoning and anthrax; they can be obtained from the Government printer. The returns for June last show that there were 48 cases of lead-poisoning and 4 of anthrax. Four deaths from lead-poisoning were also reported. Moreover there were 17 cases—with five deaths—from lead-poisoning in house painters. The figures for the first six months of the year are slightly better than those for the corresponding period of 1906, viz.:—1906.—342 cases of poisoning and anthrax, with 28 deaths, and 82 cases of lead-poisoning in painters, with 21 deaths. 1907.—261 cases, with 20 deaths, and 74 cases, with 22 deaths respectively.

Dubious.—The condition you describe has been called "Salaam Convulsion." It is not pathognomonic of any condition, for it occurs (besides in Spasmus Nutans) in epilepsy and Menières' disease, and is also seen in teething disturbances in rickety children.

DOCTORS HARD TO PLEASE.

"**Valetudinarian**" writes:—

"Having been under the care of doctors lately, I am told that if I wish to keep in good health I must follow these instructions:—

"'Eat only a light breakfast'; also, 'Breakfast should be the best meal of the day.'

"'Run or walk two miles before breakfast'; also, 'Never attempt to do anything on an empty stomach.'

"'Take a cold bath the first thing in the morning'; also, 'Remember the shock to the system of suddenly entering heat or cold is very injurious.'

"'Never use a pillow'; also, 'The most refreshing sleep is obtained when the head is elevated.'

"'Do not get into the habit of sleeping in the daytime'; also, 'Always take a nap in the afternoon.'

"'Eat only at meal-times'; also, 'Eat whenever you feel hungry.'

"'Get up at 5 o'clock every morning'; also, 'Sleep until thoroughly rested, no matter how late it is.'"—*News.*

Pater.—The average composition fee for the complete five years' course at a London hospital is about 130 to 140 guineas. This includes practically everything; but in event of failure to pass exams it does not always include second courses in practical classes. The fees may be paid in one sum, or in instalments, but the latter plan is rather more expensive. As a rule the fees for the London University classes run a little higher than those merely for the conjoint diploma. The difference averages about 10 or 12 guineas. Athletic subscriptions, instruments, books, dissecting parts are, of course, extras.

A Chemical Student.—In writing analytical reports, sometimes the volume percentage is desired, sometimes the weight percentage, and sometimes the percentage of alcohol expressed as proof spirit. As the great majority of alcohol determinations are returned as "by volume," except in the case of figures for the Inland Revenue, our reports are usually put in this form.

Vacancies.

Clifden Union.—Medical Officer. Salary, £140 a year, and £20 a year as Medical Officer of Health, together with Vaccination Fees. Applications to the Presiding Chairman, T. King, Clerk of Union. (See Advert.)

Royal Victoria Eye and Ear Hospital, Dublin.—House Surgeon. Salary, £40 per annum, with rations. Applications to E. Parker, Registrar. (See advert.)

Glasgow District Asylum.—Assistant Medical Officer required at Woodilee, Lenzie. Salary, £135 per annum, with board, lodging, washing, etc. Applications to the Medical Superintendent.

Bridgnorth and South Shropshire Infirmary.—House Surgeon. Salary, £110 per annum, with board and lodgings in the Infirmary. Applications to the Hon. Secretary, the Infirmary, Bridgnorth.

Birmingham General Hospital.—Receiving Room Officers. Salary, £150 per annum. Applications to Howard J. Collins, House Governor.

Egyptian Government.—Kasr El Ainy Hospital.—Resident Medical Officer. Salary £250 a year, with quarters, servants, washing, coal, and light. Applications to the Director-General, Public Health Department, Cairo

Egyptian Government.—Ministry of Education.—School of Medicine, Cairo. Assistant to the Professor of Pathology. Salary, £E.320 per annum. Applications to be addressed The Director, Government School of Medicine, Cairo, Egypt.

Worcester County and City Asylum.—Third Assistant Medical Officer. Salary, £140 per annum, all found. Applications to Superintendent Powick, Worcester.

Devon County Asylum.—Assistant Medical Officer. Salary, £140 per annum, with board, apartments, and laundry. Applications to the Medical Superintendent, Exminster.

Prestwich, Manchester, County Asylum.—Junior Assistant Medical Officer. Salary, £150 per annum, with board, furnished apartments, and washing. Applications to the Medical Superintendent.

Loughborough and District General Hospital and Dispensary.—Resident House Surgeon. Salary £100 a year, with furnished rooms, attendance, board, and washing. Applications to Thos. J. Webb, Secretary.

Aberdeen Provincial Committee for the Training of Teachers.—Lecturer on Hygiene. Salary £400 per annum. Applications to George Smith, Director of Studies, Training College, Aberdeen.

Manchester Township.—Assistant Medical Officer. Salary £110 per annum, with furnished apartments, fire, light, washing, and attendance. Applications to James Macdonald, Clerk to the Guardians, Poor Law Offices, New Bridge Street, Manchester.

London County Asylum, Long Grove, Epsom, Surrey.—Fourth Assistant Medical Officer. Salary £180 a year, with board, furnished apartments, and washing. Applications to H. F. Keene, Clerk of the Asylums Committee, London Asylums Committee Office, 6 Waterloo Place, S.W.

County Asylum, Mickleover. Derby.—Junior Assistant Medical Officer. Salary £120 per annum, with furnished apartments, board, washing, and attendance. Applications to Dr. Legge.

Appointments.

Battersby, James, F.R.C.S.Eng., Lecturer on Anatomy in St. Mungo's College, Glasgow.

Danvers, H., M.D. Parma, L.R.C.P. and S. Edin., L.F.P.S. Glas., Assistant Physician to the Italian Hospital, Queen's Square, W.C.

Ellison, Francis Charles, M.D. Dub., Resident Medical Superintendent at the Mayo County Asylum, Castlebar.

Knox, Robert, M.D. Edin., M.R.C.S. Eng., L.R.C.P. Lond., Medical Officer in charge of the Electrical Department at the Great Northern Central Hospital

Muir, Gavin D., M.B., Ch.B. Glasg., Resident Medical Officer at the Royal Albert Hospital, Devonport.

Penny, Sydney Greenwood, L.R.C.P. Lond., M.R.C.S., Medical Officer for the Fourth District by the Penzance Board of Guardians.

Births.

Fraser.—On August 14th, at 36 Moray Place, Edinburgh, the wife of John S. Fraser, M.B., of a son.

Hay.—On August 15th, at Ancaster Drive, Anniesland, Glasgow, the wife of A. G. Hay, M.D., of a son.

Key.—On August 12th, at Valetta, Clarendon Road, Southsea, the wife of Aston Key, M.B., B.C., of a daughter.

Martin.—On August 16th, at 1 Marlborough Avenue, Hull, the wife of Edward Lister Martin, M.D., M.B., &c., &c., of a daughter.

Marriages.

Forrester—Hartnoll.—On August 14th, at S. John's, Potters Bar, Charles Carmichael Forrester, M.D., Public Health Department, Ministry of the Interior, Cairo, son of the late William Forrester, of Arngibbon, Stirlingshire, to Adeline Braund, youngest daughter of the late James Hartnoll, of Ganwic, Barnet.

Grayson—Walker.—On August 17th, at St John's Church, Burgess Hill, Lionel Dorrell, son of Francis Dorrell Grayson, M.R.C.S., of Rayleigh, Essex, to Gertrude Bardsley, daughter of the late Herbert John Walker, M.D., of Sheffield.

Deaths.

Adams.—On Aug. 15th, at The Lawn, Martock, Ernest Beadon Adams, M.R.C.S., L.R.C.P., Lond., late H.M.'s Colonial Medical Service, second son of J. Dixon Adams, M.D.

Coltart.—On August 17th, at Granville House, 714 Fulham Road, London, Joan Mary, infant daughter of Dr. and Mrs. Guy H. Coltart, aged 13 days.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXV. WEDNESDAY, AUG. 28, 1907. No. 9

NOTES AND COMMENTS.

Abundant Precipitation.

THE almost phenomenal amount of cold and wet which have characterised this summer may have ruined the temper and holidays of a great many, but they have at least effected a vast saving of infant life. The experience of last quarter, when, to quote the picturesque terminology of the Registrar-General, "Precipitation was abundant," was very favourable as regards diarrhœa, the rate being 0.05 below the decennial average. But just as every Juliet is judged by her balcony scene, so every diarrhœa season stands or falls by its July and August performances, and as the returns come in these are seen to have been unusually benign. In some districts, indeed, the diarrhœa deaths have fallen almost to vanishing point; in Marylebone, for instance, there were only two for the whole of July, and in Leicester for the middle week of August only one. On the other hand, in spite of the weather, cholera appears to be rolling up in considerable force. It is taking its usual overland route, and having reached Southern Russia is spreading with considerable alacrity across the steppes. The usual sanitary cordons have been placed round the infected centres, but without avail, and the disease is making great progress. It is hardly possible that cholera will gain sufficient foothold in Central Europe to cause great devastation this year, as the season is too late, but had the temperature been at all propitious it might have reached Europe earlier and caused great havoc. So that there may be greater blessings than we are aware of disguised in the "abundant precipitation" we have so abundantly abused.

Pittsburg and Appendicectomy.

WE had occasion a few weeks ago to comment on the atrocious want of good form which distinguishes what passes for "society" in Pittsburg, as instanced by the giving of "whooping-cough parties," in which prizes were given to those who had the most severe paroxysms or made the loudest noise. They seemed to us far more vulgar than the game that gutter-urchins indulge in, of seeing who can spit the furthest. The great ladies of Pittsburg are *nouvelles riches* in the most odious form, namely, that of trying to outdo the extravagances of the most *outrée* of their kind. The last report is that these gentle creatures, being tired of the usual excesses, decided by way of deriving a new sensation to have the appendix vermiformis removed. Last month eighty-four of the "leading society women" of that town accordingly had the operation carried out, although there was no surgical need for it, and their medical advisers were strongly opposed. The astonishing thing is that surgeons were found to perform a merely mutilating operation of the kind, but presumably a demand creates a supply, and money seems to be able to buy anything in Pittsburg, except good taste. It seems almost a pity that all the unavoidable fatalities of appendicectomy over a suitable period were not crowded into these eighty-four operations.

A Royal Order of Motherhood.

DR. RENTOUL, among reformers, possesses the invaluable quality of imagination, and he now comes forward with the suggestion that in order to encourage the rearing of children the Queen should institute a Royal Order of Motherhood, to be awarded to those women who have the largest and healthiest families. It certainly seems reasonable that as decorations and knighthoods galore are given for the destruction of human life, a little reward should occasionally reach those who devote themselves to its creation and nurture. True, there is the King's Bounty for triplets, but after all the bearing of triplets reflects but little glory on the mother, and for State purposes these pleonastic births are of little use, as the infants almost invariably are puny and not infrequently die within a few hours. In these piping times of peace and International Congresses, the slaying of men is happily a less popular and lucrative trade than of yore, and, contemporaneously, but perhaps not etiologically related to this decline, is the fall in propagation of mankind, so that it might be well to make the begetting of children as honourable a business as the slaughter of adults. Both are ancient and popular pursuits, and the former has the additional recommendation of economic utility.

Triplets and Trouble.

THE death of triplets caused an interesting point to arise at Barnes last week. A medical man, Dr. H. P. Daniell, attended a woman who was confined of triplets. One of the children was born dead, and the other two died shortly after birth. Not being satisfied as to the cause of their sudden deaths, Dr. Daniell declined to give a certificate, but he wrote on a piece of paper the fact that the children died shortly after birth.

This document not being a valid certificate, as indeed it was not intended to be, the children could not be buried and, as the result of the pother that ensued, Dr. Daniell was summoned on no less than six charges by the Registrar-General for unlawfully refusing, without reasonable excuse, to give a certificate. Counsel for the prosecution, after giving his version of the affair went so far as to state that Dr. Daniell was trying to get money out of the affair by making post-mortems on the three children and giving evidence at three inquests. What evidence there may have been on which to rest this charge the prosecuting counsel did not call, and as it was shown that when interviewed by the coroner's officer and told there was to be no inquest, Dr. Daniell still refused to give a certificate it may be taken that there was pretty cogent evidence against the suggestion. The evidence that the prosecution called, namely, that of the coroner and the police surgeon who had viewed the bodies was to the effect that there was no reason from what they knew of the circumstances to suspect foul play, and Dr. Daniell, simply stated that he did not know why the children died and therefore proceeded to throw the onus on the coroner.

Opinion and Practice. Now, as a medical man is required to state on a certificate what in his opinion is the cause of death, it is obvious that if he has no opinion he cannot certify. In practice when a medical man has no reason to suspect foul play he usually fills in a certificate to save his patients the pain of an inquest, but this position is a compromise with the very bad law regarding certification. Not only is the law bad, but it is also both mean and harsh, for besides providing no payment for the medical man's opinion, it penalises him if he does not certify. And it is still more illogical in not precribing any procedure in the case of a medical man being unable to certify. Again, what happens practically is that a medical man usually writes an unofficial note to the coroner, but this he is by no means bound to do, and certainly the State has no right to expect it of him. It is such distasteful work to quarrel with forms and ceremonies in connection with death that medical men have long suffered under this unjust law, when all that is necessary to correct it is a general refusal to give information.

Law and Logic. DR. DANIEL has stood on his strict rights, and his action has given the authorities some trouble; he has, therefore, been subjected to the ignominy of police-court proceedings in order, as they would probably say, "to bring him to his senses." As a matter of fact the people who need bringing to their senses are those who frame unjust laws and administer them by inquisitorial methods. In the case in question there were two magistrates on the bench and they disagreed in opinion, so that the case is one which obviously presents complex issues, and when one reflects that hundreds of persons, principally children, are buried every year without certificate and without inquest, the farcical nature of the whole administration of the law is at once revealed. Attempts are made to bully and cajole medical men, after giving the State free information, to make them give it in certain words most convenient to the Registrar-General. In fact registrars often make great difficulty about accepting certificates except according to the nomenclature of the College of Physicians, and to save patients annoyance medical men have to submit to this slight. As the Registrar-General is paid a handsome salary and given a large staff to assist him, any difficulty in the classification of a death should certainly fall on him, and not on a private practitioner, who has already given more information than can reasonably be expected from him.

LEADING ARTICLES.

THE RATIONAL ECONOMY OF SANATORIA FOR CONSUMPTIVES.

THE slow and gradual evolution of public health matters is apt to discourage scientific enthusiasts who devote their energies to that particular field of work. The old proverb which reminds us that "Rome was not built in a day" applies with emphatic point, *mutatis mutandis*, to the practical adoption of fresh truths into our national system of sanitary administration. Take the case of consumption, the study of which was first placed on a sound scientific basis by the demonstration of its specific pathogenic organism by Koch in 1882. Twenty-five years have elapsed since the announcement of his great discovery, and the whole question raised thereby has been the subject of universal interest. It may safely be said that no matter in the whole range of medical affairs has received a greater amount of serious discussion, both inside ond outside the profession. It has taken more than a quarter of a century to decide authoritatively that bovine and human bacillus tuberculosis are identical. As a corollary it has taken an equal period of time to arrive at the conclusion that infected milk must henceforth be regarded as the probable source of much of the terrible incidence of tuberculosis upon our infantile population. That result, it must be acknowledged, has been arrived at short of actual practical demonstration of such transmissibility. The slow incubation of the disease and the difficulty of establishing adequate and absolute proof of infection in individual cases render the application of any direct logical processes well nigh hopeless. There are sufficient data, nevertheless, to enable us to form a reasonable inference as to which direction will be taken by the balance of probabilities. Given a specific bacillus shown to exist in man and to be extremely prevalent in cows, the milk of which is infected thereby; given the use of cow's milk as the staple food of infants and children; and given the existence of a terrible mortality from tuberculosis amongst the infantile population; then it is not altogether unreasonable to assume that the bacillus in the cow is more or less answerable for the disease among children. That assumption, at any rate, appears to afford the best explanation that can be framed in our present state of knowledge. It is open to those stern logicians who demand more stringent logical proof of the relation of cause and effect in this particular case to advance a more probable and a more convincing working theory, that will be more in consonance with the facts so far as they are known to us. Meanwhile, the recognition of the infectivity of phthisis has led to a great diminution in the disease; whatever doubts may surround etiology, there emerges the distinct and gratifying fact that modern science is gradually ousting the malady. At best, however, the campaign is slow and protracted, resembling the ancient wars that lasted for many years rather than the sharp contests of modern warfare. It may be said that one great and sweeping strategic movement will consist in the eradication of tuberculous meat and tuberculous milk from our food supplies. In any case, it is tolerably safe to assume that the actual cure of consumptives will play a comparatively small part in the ultimate eradication of the disease, which is the only permissible goal of the scientific sanitarian. Nevertheless, on humane and other grounds, it is clearly the duty of society to neglect no means whereby the disease may be held in check, especially amongst our working-class population. Among the practical achievements of which the past quarter of a century has reason to be proud is that of the open-air treatment of consumptives. In the attempt to render that method available, huge sums have been spent on special sanatoria. After the lapse of a few years it seems likely that the erection of costly buildings for the purpose is already obsolete as a practical scheme. In one notorious instance the prime cost has reached as much as £1,000 per bed, and even then only a minimum of gratuitous relief is available. A correspondent to a London newspaper recently showed that a serviceable garden bedroom, constructed on three sides by matchwood boarding covered with tarpaulin, and on the fourth by a blind, could be constructed at a cost of £2. Instead of a bed costing £1,000 it would be simpler to erect 500 beds at £2 each, and to devote the interest on the vast capital sunk in founding the remaining £1,000 beds in providing a medical, nursing and commissariat staff and the necessary maintenance of patients. Even now the mistake of the big sanatoria might be to some extent remedied by selling them for other purposes, and then devoting the purchase-money to sanatoria on more economical and rational lines. The main curative problem is to get at the working-man consumptive in the early stages of the disease, and to restore him as an effective worker in the industrial army.

MR. JOHN BURNS ON THE NOBILITY OF THE MEDICAL PROFESSION.

THE notification of the Births Bill passed its third reading in the House of Commons on Friday last. As many of our readers know, the measure is in the charge of Mr. John Burns, President of the Local Government Board. The intention of the Bill is sound enough, inasmuch as it aims at securing an important administrative return. Incidentally, however, it throws upon the medical profession a new duty, as recently insisted upon in our columns, without providing for the payment of any fee. More than that the Government has now actually made it penal for medical men to refuse to discharge gratuitously the responsible service thus thrust upon them by the State. The legislature has in this way marred the statute book with a monstrous violation of the rights of an honourable profession. In refusing the amendment which would have freed medical men from the obligation to sign such a certificate Mr. John Burns made some remarks that are worthy of attention as showing the characteristic attitude of legislators with regard to our profession. He said in effect that it was a matter of extreme regret to him that a great, honourable and charitable profession should have practically dissociated themselves from what he believed to be one of the most beneficient movements of recent years. Let Mr. Burns compare a parallel case. Criminal law reform may be described equally, if not far more so, as one of the most beneficient movements for the proper administration of justice in this country that has been witnessed for centuries. Would Mr. Burns on that account ask the lawyers to undertake important professional duties imposed by a new Criminal Law Reform Act without fee or reward? We trow not. The lawyers in and out of the House would treat the suggestion as a farcical joke. Why then should Mr. Burns seek to exact the rendering of responsible legal documents gratuitously from another learned profession? Medical men cannot live on honour and charity alone, and it is precisely in ratio to the loftiness of their principles and of their lives that the Government should consider the question of their remuneration for services rendered to the State. At present the Government exacts much money and many stringent conditions in return for a legal medical qualification. It then abandons the duly qualified practitioner to the unrestricted competition of every quack and charlatan who chooses to batten on the community. Of all men we should have thought Mr. John Burns the first to concede the principle that the labourer is worthy of his hire. Possibly he has grown so accustomed to the generous prodigality of medical science that he regards it as fair play to any Minister wishing to carry out his measures economically. However, as the Bill now stands, medical men will be subject to prosecution for refusing to sign a gratuitous birth certificate. The thanks of the profession are due to Dr. Cooper, M.P., who fought their cause in the House, and we only regret he was compelled to withdraw from the position of demanding fees for the signature of the certificates in question. If lawyers had such a duty thrust upon them they would probably resist, to a man, and it is a question how far the doctrine of passive resistance might be accepted by the medical profession with advantage in this and other matters.when their corporate rights are threatened and invaded. The Government could hardly complain if medical men throughout the kingdom refused to sign certificates forced on them under such conditions.

CURRENT TOPICS.

Typhoid Epidemic at Peterhead.

PETERHEAD has been for some time past in the throes of an epidemic of enteric fever. Fortunately it appears to be on the decrease, as the last weekly report shows eleven cases as against twenty-four for the preceding week. The total number of cases at that time was 341, which is a somewhat serious percentage of a population returned as 13,674. An investigation has been made by Dr. Matthew Hay, of Aberdeen. From his interim report it appeared that the origin of the epidemic lies in the water supply. It seems that the sources were subject to considerable pollution at the time when the outbreak begun and from the report it is clear that a great deal remains to be done before the supply can be regarded as safe. The incident emphasises the need of unrelaxing vigilance in the control of a water supply from its sources and all along the line. Neglect of this supervision is apt to be followed by a terrible nemesis in the shape of sickness, death and commercial disaster to a whole community. One of the clearest lessons of modern sanitary science is the absolute need of the provision and maintenance of a pure water supply.

Mr. Gladstone and Alcohol.

THE perennial problem of " doctors and drink " —as the lay journals tersely dub the topic—receives day by day fresh and amusing comments from newspaper correspondents. Recently one writer said that Mr. Gladstone was often a great deal at his father's house, and one day, then a boy, leant over the dinner table and said to him, " There are few things better in this world than the pint glass of champagne on a hot summer's evening." He gently hints that the great man's first was not his last, and was eked out later with two or three glasses of port, not light port from the wood, but heavy vintage wine of 1863. This interesting bit of biography will be held by many moderate drinkers to afford pretty strong testimony to their view of the case, namely, that alcohol in reasonable quantities is consonant with the highest sustained intellectual and bodily fitness. Not so with the narrator of this incident, who remarks that " it is positively appalling to try to conceive what Mr. Gladstone one of the giant intellects of his own or any other age, and one of the strongest men physically, might not have done had he not poisoned both his mind and body consistently during his long and active life." This attitude reminds one of the gentleman who informed a teetotal audience that he had smoked and drunk all his life and was still hale and hearty at ninety-six years of age, when the lecturer retorted there was no knowing what age he would have reached had he not " tasted the poison at all—at all."

Death from Easton's Syrup.

A RECENT prosecution, instigated by the Pharmaceutical Society under the Sale of Poisons Act, deserves the attention of medical men, inasmuch as it calls attention to a risk that would otherwise hardly receive attention. The defendants were " Boot's, described as Cash Chemists," who sold a bottle of tablets of " Easton's Syrup " to a customer without making any entry in the poison book, although each tablet contained 1-64th of a grain of strychnine. By some inadvertance the bottle got into the hands of a baby, who swallowed about seventeen tablets and died in half an hour. The manager of Boot's admitted that two such bottles would contain enough strychnine to kill a man. A fine of £5, with 25s. costs, was inflicted. Now that the danger has been pointed out it is probable that chemists will take care to impress their customers with the nature of such a preparation. It seems still more likely that the manufacturers of the tablets will cease to put up the drug in tablet form, especially as there seems to be no particular advantage over the fluid form in which it is usually prescribed.

Urticaria and Military Service.

THE subject of urticaria, owing to the recent prominence in a London police court, is likely to leap into considerable prominence in the medical world. Without in any way discussing the legal issues involved it may be interesting to call to mind some of the chief facts of the malady in relation to the physical disability or otherwise of the sufferer. The origin of the affair was the prosecution of a Birmingham Yeomanry trooper for absenting himself from the annual training. He was arrested and brought to London under military escort, and when brought into Court presented the magistrate with three medical certificates, stating he was unfit to attend the training on account of urticaria. The medical officer of the Yeomanry suggested that the malady in question was not serious enough to warrant defendant's absence. Owing to the cost of bringing the medical witnesses from Birmingham the defendant's side of the question was not supported medically at the first hearing, but the magistrate adjourned the case so that the evidence of the signatories could be obtained. When the case was heard again the defendant's case was supported by three medical men, one of them being a well-known Birmingham dermatologist, and the magistrate, in view of their evidence, could only find that the trooper's absence was justified. There is, of course, urticaria and urticaria, but few who have seen a really severe case with its attendant fever, prostration, vomiting and general misery, would wish to see the patient on horseback playing the part of one of the Empire's defenders.

Infection from Old Bottles.

A point of some importance was raised by a deputation from the National Glass Bottle Hawkers' Trade Union, which recently waited on the President of the Local Government Board, with the object of directing the attention to the danger to public health involved in the indiscriminate use of old bottles. There is little doubt that bottles collected from ash-pits and other unsavoury surroundings, are, with no more than a perfunctory cleansing, again put to use. It is not improbable too that bottles from the sick-room of an infective patient are occasionally returned to the druggist for re-filling without sufficient disinfection of the exterior. In this way infection is liable to be carried from the sick to the healthy. It is doubtful whether the interference of the Local Government Board in the matter would be likely to result in any good, but the deputation has done useful work in drawing public attention to a possible danger. The cleansing of a glass bottle is, in most cases, a sufficiently simple matter, and when any difficulty presents itself, it is better that the bottle should be destroyed than that any risk should be run.

The Cardigan Cancer-"Curers."

AN interesting but rather odd article on the Welsh Cancer-"Curers" appears in the current number of *The Crown, the Court and Country Family Newspaper*. It is from the pen of Dr. W. R. Hadwen, and its curious nature consists in this that while it contains mainly facts and opinions which form a ruthless *exposé* of these persons, at the same time they themselves are throughout spoken of in terms of toleration, if not of indulgence. The brothers are no doubt enthusiasts, especially the elder, Daniel, but if men are so blinded with enthusiasm for their own gain as to cause intense unnecessary suffering to people, it becomes the duty of the Public Prosecutor to proceed against them. There are certain kinds of barbarous enthusiasm with which the State becomes intimately concerned, and even in India and Africa cruel native customs which are part of their very religion are suppressed. The tale told by Dr. Hadwen is a ghastly one. These brothers, glutted with semi-religious fervour, but jealously guarding their precious "secret"; crowds of wretched sufferers tortured with the pangs of cancer enhanced by the "remedy"; dead and dying and suffering from every country of the globe, in every quarter of the little town; sufferers with awful wounds sent home as "cures" when their patience, money, or credulity has given out; cancer diagnosed in every case and whole organs charred in the caustic application; and an analysis of the "Secret Oil," which was obtained from part of an eschar, and found to be composed of zinc chloride with traces of arsenic and antimony. There are some hundreds of these wretched patients, and applications are pouring in every day from fresh ones, while money seems to be rolling in on every side. We ask, in the name of good government and common humanity, if this state of affairs does not form a *prima facie* case for the attention of the Public Prosecutor.

Roof Gardens.

ONE of the penalties paid by mankind for the privilege of living the corporate life of great cities is the excessive value attached to the necessarily limited land area. All sorts of shifts are adopted in order to make the most of an available area. The most obvious is to build skywards, on the plan adopted in ancient walled cities. Another is to burrow beneath the earth's surface, as in the case of the tube railways. One of the most recent movements is to utilise the roof tops, after the manner of some Eastern countries. There is no particular reason why a hanging garden should not exist on most of our modern roofs, provided always that the jerry-builder has not been concerned in providing walls unequal to any additional strain. Where gardens are not adopted it would be feasible to erect glazed conservatories for recreation purposes. Sir Lauder Brunton, who advocated this departure at the recent Housing Congress, put the matter in a nutshell when he said that our roofs should be flat instead of sloping, "terraced, with covered parts to shelter from rain and sun, and with walls high enough to prevent accidents." As a matter of scientific fact, the air at the level of roofs is purer than that of the roadway in direct proportion to the altitude.

PERSONAL.

THE PRINCE OF WALES, as Grand Prior of the Order of St. John of Jerusalem, has awarded the gold medal of the Order to Dr. Albert von Lecoq, of Berlin, for marked heroism during attendance on an English officer in Turkestan.

WE are asked to announce that H.H. Prince Henry zu Schönaich-Carolath has consented to act as president of the fourteenth International Congress of Hygiene and Demography. Dr. Rubner, Privy Councillor of Medicine, Professor of Hygiene at the Royal University of Berlin, and Professor Dr. von Mayr, Under-Secretary of State, Munich, will be vice-presidents.

SURGEON-LIEUT.-COLONEL C. R. KILKENNY, C.B., Medical Superintendent to Officers' Convalescent Home, Osborne, Isle of Wight, has been appointed a Member of the Fourth Class of the Royal Victorian Order.

LIEUT.-COLONEL JAMES WISE, R.A.M.C., Principal Medical Officer, has been appointed an Official Member of the Legislative Council of the East African Protectorate.

DR. OLIVER C. MAURICE, Consulting Surgeon, to the Royal Berks Hospital, Surgeon to H.M. Prison, Reading, whose death was recently recorded in these columns, has left estate valued at about £26,000.

A TESTIMONIAL is to be presented to Mr. John Carswell as a mark of sympathy with him in the recent attack made by a lunatic whom he had recently certified. The honorary treasurer is Mr. Nicoll, City Chamberlain of Glasgow.

ANY friends of the late Major D. M. Moir, professor of anatomy at Calcutta, wishing to subscribe to a fund now being raised for a memorial are requested to communicate to Captain F. R. Connor, I.M.S.. or to Rai Bahadur Dr. Hira Lal Basu, the honorary secretaries.

WE regret to learn that Dr. D. Nicholson, C.B., a Lord Chancellor's Visitor in Lunacy, has sustained considerable injuries in a cab accident. Dr. Nicholson is progressing favourably.

A CLINICAL LECTURE

INFANTILE DIARRHŒA.

By G. F. STILL, M.A., M.D., F.R.C.P.,

Professor of Diseases of Children, King's College, London.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

I HAVE chosen rather a hackneyed subject for my lecture this afternoon, but it, at any rate, possesses the interest which belongs to the commonplace, for I suppose all of us are concerned at some time or other in dealing with the dangers and difficulties of infantile diarrhœa.

In the first place, let me show you some statistics which emphasise certain points of practical importance.

	DEATHS FROM ALL CAUSES IN LONDON.			DEATHS FROM DIARRHŒA IN LONDON.		
	Total under 1 year old.	Under 3 months.	3 months to 6 months	Total under 1 year.	Under 3 months	3 months to 6 months
1891	20,776	9 662	4,286	2,272	608	742
1892	20,441	9,614	4,162	2,340	745	845
1893	21,814	10,282	4,752	3,265	953	1,144
1894	18,812	9,083	3,680	1,866	518	620
1895	22,252	10,091	4,755	3,803	1,024	1,282
1901	19,678	9,565	4.113	4,029	1,071	1,383
1902	18,307	8,927	3,545	2,542	590	859
1903	17,223	8,594	3,463	2,818	729	981
1904	19,012	9,050	3,948	4,408	1,076	1,474
1905	16,603	8,253	3,224	3,347	869	1,092

Notice that there are between 2,000 and 4,000 deaths annually in London under the age of one year from infantile diarrhœa, and that the number, so far from diminishing during the past ten years, has rather increased. The series of years I have taken at random. It may be objected that there is a possible fallacy, namely, that a larger area may be included under the term London in one period than in another; but this fallacy is avoided by regarding the proportion of deaths due to diarrhœa relatively to those due to all causes. In 1891, nearly one-tenth of the deaths under one year of age were due to diarrhœa. In 1901, the fraction rises to one-fifth, or twice the relative number. This fact has a practical bearing. We hear a great deal about the advances which have been made in regard to sanitation, about municipal milk depôts, and so on; but it is clear, in spite of all boasting to the contrary, that the cause of infantile diarrhœa remains, the mortality from that disease has increased instead of decreased; the reduction of the infantile diarrhœa mortality calls for some other remedy besides improvement of the milk supply and of the methods of artificial feeding. This table shows a striking difference in the proportion dying under three months compared with those between three and six months, the latter being always the more numerous. In 1891, 9,662 died from all causes under three months of age, and out of that number 608, or one-sixteenth, died from diarrhœa. In the same year there were 4,286 deaths between three and six months from all causes, and 742 in the same age period from diarrhœa—or about one-sixth. At first sight this appears contrary to all we know as to the liability to diarrhœa and its danger at those ages. We know from clinical experience that the infant under three months old who has diarrhœa is in much greater danger than is a baby between three and six months old; yet the number of deaths is much less at that age. The explanation is obvious: that the infants under three months old are breast-fed for the most part; but breast-feeding is progressively less frequent as the infant becomes older. There, I take it, lies the key to the reduction of infant mortality in this country, the encouragement of breast-feeding and the instruction of mothers as to the importance of suckling their infants as long as possible. This is being realised more and more by the people, and among the hospital class the advice which has been steadily tendered at children's hospitals is bearing fruit. The paramount importance of breast-feeding comes out very strikingly from statistics of the fatal cases. I investigated cases at the Children's Hospital, and found that 96 per cent. of the infants who died of infantile diarrhœa were hand-fed; 92 per cent. out of the 96 per cent. were hand-fed entirely, the remaining 4 per cent. had had both kinds of feeding. Only 4 per cent. of the deaths from this disease were in children who had been entirely breast-fed. So breast-feeding, or even partial breast-feeding, is the great safeguard against diarrhœa.

Now let me draw your attention to a very practical point, which is not generally realised, namely, the part played by condensed milk in the causation of infantile diarrhœa. I have been told by practitioners that they order condensed milk because it is sterile, and therefore so much safer. But so far from this being true, condensed milk seems to be particularly dangerous, and the child who is taking it runs a special risk of having summer diarrhœa. I have kept a note of the feeding of a large number of babies, and I find that 12 per cent. of infants brought to hospital had been fed upon condensed milk, whereas of the fatal cases of diarrhœa, 25.8 per cent. had been fed upon condensed milk.

The mode of feeding is not the only factor in the production of this disease; temperature is also important. And if this is so, we may expect a reduction in the mortality this year. I show you a chart, based upon the Registrar-General's returns of deaths, and the Greenwich Observatory records of temperature, *i.e.*, the mean weekly temperature. At first glance, the curves do not seem to agree, but on closer inspection they do so fairly closely. The rise in the temperature curve naturally precedes by three or four weeks the rise in the death curve, because the disease takes some time to kill—usually three or four weeks.

What is the connection between high temperature and infantile diarrhœa? Clearly it is not the heat alone which increases the death-rate, or

---

(a) Delivered at the Medical Graduates' College and Polyclinic, July 9th, 1907.

breast-fed children would suffer equally with the others, but they do not. It has been supposed to be due to the growth of some bacterium which is present in the soil, and Ballard published some observations in support of this view; but there has been no proof of it in bacteriological research since. There is the obvious suggestion that it is something carried by milk, but we have no proof even of that. Several bacteria have been described, within recent years, as the cause of infantile diarrhœa, but none of them have been shown to exist particularly in the food which the infant takes. Another possibility is that the bacteria which cause the disease are normal inhabitants of the intestine and only become pathological under certain conditions—that when an irritating food is given repeatedly to a child the intestines become much more liable to invasion, and permit of a rapid growth of bacteria. As an American writer puts it: repeated insults to the intestine make it particularly susceptible to bacterial invasions.

Some reference I must make to the classification of diarrhœa, because it has some bearing on treatment, and it is of treatment I wish particularly to speak. All sorts of elaborate classifications have been suggested, some based upon bacteriological grounds, some upon clinical observation, and some upon morbid anatomy. Many of those given in text-books are of but little value for clinical purposes; they assume more than we know. I think the simplest way is to divide them into two, or possibly three, groups:—(1) Simple gastro-intestinal catarrh, which some people call "intestinal dyspepsia," that is, simple diarrhœa due to some faulty food. (2) The more severe form known as gastro-enteritis with ileo-colitis, in which there is a rise of temperature possibly due to some infection. It includes "summer diarrhœa" and "febrile diarrhœa." (3) The most severe form, known as cholera infantum, in which the child, in twenty-four hours, is almost moribund. I doubt very much whether even such a classification has any really solid ground to rest upon. It amounts, after all, to little more than a distinction of degrees of severity. It is often impossible to distinguish between gastro-intestinal catarrh and gastro-enteritis. I have no doubt there is a difference between the simple diarrhœa in the child whose food is indigestible, and the severe diarrhœa which comes on in the middle of summer. But there are cases in which it is difficult to draw the line; they seem to merge the one into the other. I do not know of any proof that cholera infantum differs from severe gastro-enteritis, except in the "rice-water" stools, and the fulminating course. Until we know a difference in ætiology, our distinctions are somewhat premature. However, the treatment of some of these conditions differs from the treatment of others. You may be able to say that in one child the lower part of the intestine is affected more than the upper, although you may not be able to say what the change is. You know that the child's colon is distended and that it is passing much mucus and streaks of bright blood in the stools, and that it suffers from tenesmus, and gets prolapse, and you are justified in supposing that there is some colitis or ileo-colitis. Another child may not be passing either blood or mucus, but vomits and has loose watery stools. We say such a child has gastro-enteritis, and the treatment will differ correspondingly.

I have not time to say much about the complications of infantile diarrhœa, but one which is very apt to be overlooked is otitis media. In all acute diseases of infancy and early childhood, this is a very common complication, and the symptoms are often wrongly interpreted. The infant suffering from diarrhœa begins to scream and the screaming is supposed to be due to pain in the abdomen, but it is not, and in a few days the child is found to have a discharge from the ear. Such a child may have head retraction, and other symptoms reminding one of meningitis. These have been verified at autopsies as due to ear mischief; there is not necessarily any discharge from the external ear.

Now with regard to treatment, for that is my main point: I suppose there is scarcely any disease for which more methods of treatment have been suggested, yet in very few diseases is it so difficult to decide what method of treatment is likely to suit in a given case. Let me first venture to find fault with what has sometimes appeared to me to be a shortcoming in the treatment of these cases. The practitioner, when called in, finds the child very bad; he orders some medicine, and says he will call again to-morrow. But infantile diarrhœa acts so quickly that the case may have slipped through his fingers before the next day; such a child should be seen, if at all possible, three or four times a day. In the simple gastro-intestinal catarrh, little is necessary beyond an aperient to clear the bowels, and I know of nothing so good for this as the old-fashioned castor oil, which has the advantage that its subsequent effect is to constipate. The food may require to be made a little weaker, and it may be advisable to give opium.

It is the severe forms which are difficult to treat, and, as the feeding is of prime importance, I shall consider that first. It is poor economy to attempt to feed these cases with milk diluted or modified first this way and then that. It is better to stop milk altogether at the outset; no ground is lost by so doing, for the infant does better by retaining even plain water than by having its vomiting and diarrhœa prolonged, or possibly aggravated, by some form of milk feeding. What, then, is to be substituted for milk? I put them down in the order of strength. First, veal or chicken broth (I believe these are preferable to mutton broth); next I put various cereal decoctions. Rice-water is more likely to suit than barley water. Let an ounce of rice soak for three hours in a quart of tepid water, then boil for an hour, then strain. Next I put albumen water—ordinary white of egg water. Next, something which is much used on the Continent for infantile diarrhœa, though only rarely here—extremely weak tea. At a hospital in Germany I was told it was given because the tannin had an astringent effect on the intestine; in another, that it had a stimulating effect. At any rate, it has been found useful. Lastly, there is plain water, on which a child will live for many hours, and if difficulty is found with albumen water, this is the wisest thing to give.

When the vomiting begins to subside, you can reverse the order, until finally you get back to the broth. Next to broth, on the return journey, the best thing is whey. I did not mention in this connection with the treatment of the diarrhœa, because it often prolongs the diarrhœa and vomiting if given in the early stage. In making the whey, the curd should not be broken up at first, but as the infant improves the curd may be more and more thoroughly broken up before straining off the whey, so that the infant may get a food containing more fat. The next step is to use peptonised milk, to which lime-water should be added to prevent any laxative effect. It is well to give alternate feeds of peptonised milk and whey at first. Sherry whey is another useful food as a stage in the return to milk.

A very important point is to give only small feeds. One sometimes finds the strength of the food has been reduced, but the child is having 4 oz. or 5 oz. feeds when ½ oz. would be much better. It is better to give a teaspoonful and have it kept down than an ounce and have it vomited. I believe it is often wise to reduce the feed even where there is only diarrhœa and no vomiting. An error often made is to continue too long the frequent small feeds. It is bad to continue giving food every hour if the child can take more every one-and-a-half-hours; the longer interval allows the stomach more time to rest.

In many cases of cholera infantum, the child cannot keep anything down at all. There is nothing, then, like a saline infusion under the skin. It will save lives which cannot be saved in any other way. After the infusion, the infant goes to sleep, and wakes up a different child. But in many cases this has to be a last resource, because parents are naturally averse to anything that savours of operation. Absorption of the fluid will be very slow, so it is better, if the child is apparently *in extremis*, to give some stimulant first, such as strychnine, or a mustard bath, or alcohol, until the infusion can take effect. But remember that strychnine in infants, even in very small doses, is apt to cause convulsions. I have seen this result from 1 ♏. of the liq. strych. B.P. If it is tolerated you can repeat a dose of half a minim after a couple of hours. As to the value of brandy, one is almost afraid, nowadays, to say anything about it. I have even been told that it is useless in any disease; my experience leads me to think that in infantile diarrhœa, as in many other serious diseases, brandy is extremely useful. But it is possible to do much harm by giving too large doses of it. I see infants who are having, as it seems to me, an altogether excessive amount of brandy, with the result that vomiting is actually excited, and kept up by this overdosing. For a child under six months, 10 to 15 ♏. is enough, and you can repeat this in a couple of hours, if necessary. 30 ♏. I regard as an outside dose for a child under a year, and I should not give that quantity unless I was hard pressed. I am satisfied that five drops of brandy put into a feed of whey or milk causes a feed to be kept down in some cases when otherwise it would be rejected. There is a carminative as well as a stimulant effect in brandy. The doctor should specify how long the brandy is to be continued; one has found brandy being given quite unnecessarily for weeks because the doctor had omitted to say when it should be stopped. Sherry whey must only be given under conditions in which you would use a stimulant. It has a remarkable carminative effect, and is sometimes kept down well when other preparations of milk are vomited.

As to drugs, my own experience is that there is not a great range of drugs which are of use in this disease. I know some people believe that opium is bad in infantile diarrhœa, but I should put it at the top of the list. There are, however, cases in which it does harm; and I think it is difficult in any given case to know whether it will do harm or not until you have tried. If you constipate an infant by giving opium, it sometimes happens that cerebral symptoms develop which make the case look like one of "spurious hydrocephalus." This is supposed to be due to the retention of the foul diarrhœal stools in the intestines and absorption taking place, so that there is auto-intoxication. Such a result, however, is very rare in my experience. How should the opium be given? The solid forms of opium are, I think, more useful than the liquid in infantile diarrhœa. Dover's powder is most useful; under three months old, ⅛ grain; six months, or under to three months, ¼ grain; and over six months, ½ grain. This may be repeated three or four times a day. If you have the child under close observation you can give more. If the stools are very offensive, it is good to combine it with ¼ grain of hyd. cum cretâ. If giving liquid opium during the first six weeks of life, I use tinct. camph. co. You may take it as a safe rule to give a quarter-minim dose of tincture of opium for every quarter year of age. But this, as I have said, can be increased if the child is under constant supervision.

Two other valuable drugs for this condition are castor oil and bismuth. I am not speaking of castor oil now as an aperient. There is much misapprehension about castor oil in the diarrhœa of infants. For clearing out the bowel, you use ½ drachm or a drachm. Its other use is as an astringent, and that is the use most commonly made in children's hospitals. We have there a mixture of 5 ♏. castor oil, 15 ♏. mucilage of acacia and dill water to 1 drachm. This mixture is almost as constipating as opium; it has no aperient effect whatever. If you give a baby six weeks old 5 ♏. of castor oil, you will occasionally get an aperient action, and 10 ♏. will usually cause such action. So for a baby six weeks old I order 4 ♏. It must not, however, be ordered every three hours, as one orders bismuth, else its effect will be aperient.

Bismuth is best given, I think, in a mixture, for the reason that the baby with bad diarrhœa is of course craving for drink, and will take the medicine in a drink; whereas if you give it a dry powder it will vomit on that account. In other conditions also you will find some children will never take powders. You need to give 5 to 10 grs. of bismuth carbonate, and you can give it every two or three hours. Some people think a great deal of disinfectants for infantile diarrhœa. They should, theoretically, do good; but my experience with them in the acute diarrhœa of infants has been most disappointing. They are useful in chronic conditions where the bowels are opened four or five times a day and the stools are offensive and the child is wasting.

There is a difference between the treatment of a case where the colon seems to be chiefly affected, and one in which the stomach is chiefly at fault. Put tersely, I should say give bismuth where there is gastro-enteritis; castor oil where there is ileo-colitis. Castor oil seems to have a very soothing effect on colon conditions; also in children with big abdomens, who are passing a great deal of mucus, and perhaps wasting like a case of tubercle. The acuter cases of ileo-colitis often do much better with castor oil than with bismuth; whereas, the child with much vomiting and loose watery stools will do better with bismuth.

Rectal irrigations are useful where there is ileo-colitis, and the child passing much slime. Some use antiseptics, others astringents, and others plain saline for the irrigations. Plain saline is, I think, as good as any. You can use 2 per cent. resorcine and tannic acid, but I do not think they do more good than plain saline; it is largely a question of washing out the intestine.

A valuable drug in cases of diarrhœa arising from affection of the colon, particularly in acute diarrhœa running on to a sub-acute condition, is silver nitrate, given in ⅛-grain doses in distilled water, perhaps sweetened with saccharine. I have tried ordinary astringents, and given an extensive trial to hæmatoxyline and catechu, and preparations of tannic acid brought out recently, and I think they are of very little use in acute cases. They are more useful in sub-acute cases.

In treating cases of acute infantile diarrhœa you must watch your patient almost from hour to hour. It is no use going on day after day with a particular drug or a particular mode of feeding if the child is not obviously improving under it. The medical man must needs exercise a close and almost constant supervision, and must be prompt to appreciate the slightest change in the infant's condition and to adapt his treatment thereto, if he would save life in these severe cases of infantile diarrhœa.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Professor F. Raymond, M.D., of the Faculty of Medicine of Paris; Physician to the Salpêtrière Hospital, Paris. Subject "Abortive Forms of Tabes."*

ORIGINAL PAPERS.

A CASE OF THORACIC LYMPHO-SARCOMA. (*a*)

By JOBSON HORNE, M.D., B.C., CANTAB.,

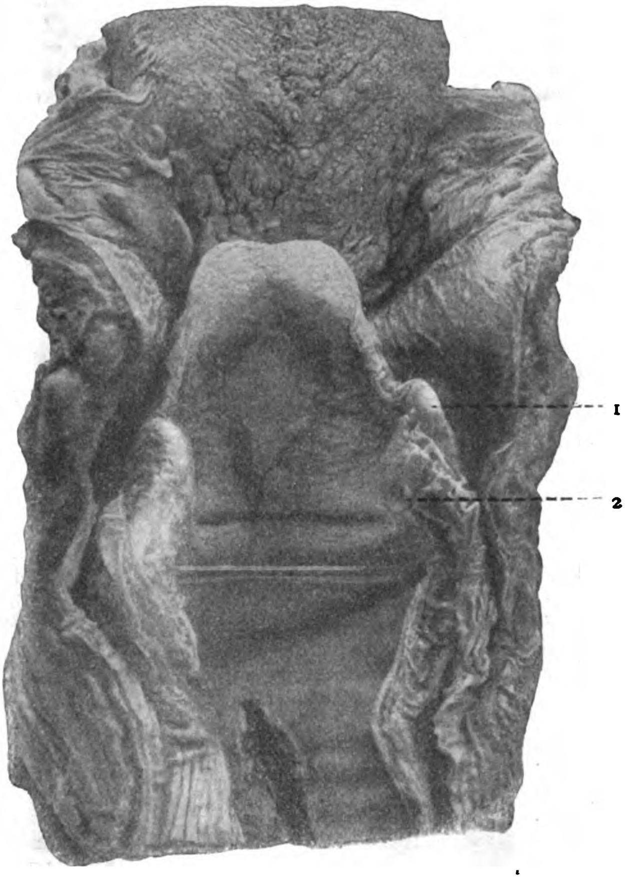
Surgeon, Metropolitan Ear, Nose and Throat Hospital, London, etc.

Clinical history.—The patient, a man, æt. 49, was quite well up to two months previous to his death, his weight being fifteen stone. He first noticed an increasing inability to eat meat, and within a month of the onset of this difficulty he was unable to take solid food, the attempt causing vomiting. He was able to take liquids by drinking fast, only about a teaspoonful returning from three quarters of a pint. Five weeks after the onset of the dysphagia—that is, three weeks previous to his death—there developed difficulty in breathing, which became worse, and was attended with "occasional spasm of the windpipe," so that he had to sit up. Latterly the attacks became more frequent, recurring twice a day, and lasting half an hour; they were worse at night, so that he was afraid to lie down in bed.

Condition on admission to hospital.—He had an anxious look. There had evidently been considerable wasting. The breathing was rapid, and associated with inspiratory and expiratory stridor, and much "wheezing," as if bronchial. He experienced a feeling as though a weight were on the chest along the sternum.

The examination of the thorax revealed no physical signs of aneurysm. Both sides of the chest moved equally; there was no area of dulness. The area of cardiac dulness was diminished; the cardiac sounds were normal. The larynx was observed to be congested, but the vocal cords moved well, and there was no sign of obstruction. A radiograph of the chest was not obtainable.

The œsophagus permitted the passing of a bougie of the largest size.



A photograph of the larynx opened from behind to show: (1) The localised œdema over the right artyænoid. The œdema has somewhat subsided in the process of preserving the specimen. (2) The puckered scar in the fold of mucous membrane passing down between the cartilages of Santorini and Wrisberg, and referred to by the author as the vulnerable spot of the larnyx as a source of systemic infection.

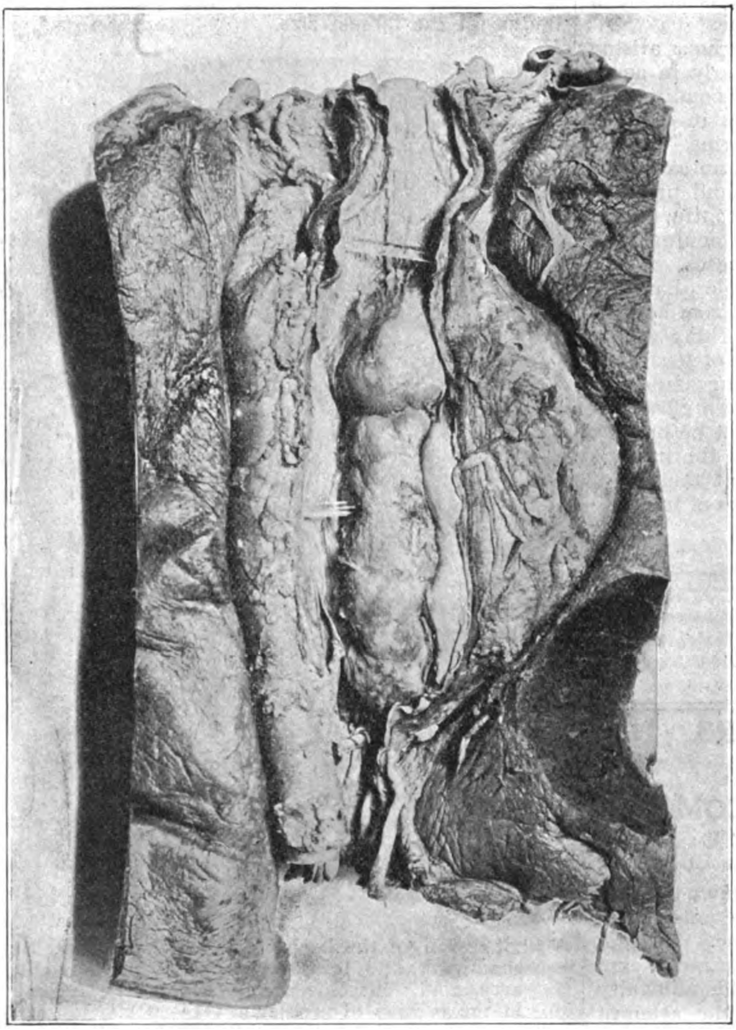
The patient rapidly became much worse, very cyanosed, and distressed, and on the second day after admission death occurred from asphyxia.

The post-mortem examination revealed in the posterior mediastinum a lobulated mass of new growth, the size of a large pear, apparently springing from the bifurcation of the trachea, and extending forwards into the pericardium, and downwards and backwards for the most part to the right of the middle line. The growth had bulged into the lumen of the œsophagus so considerably that the mucous membrane covering it was extremely thinned and atrophied, the œsophagus itself being obstructed by the new growth to the extent of 115 mm. in the vertical direction, the growth within its walls measuring 40 mm. across, whilst the entire width of the

---

(a) Paper read before the Laryngological Society of London, April, 1907.

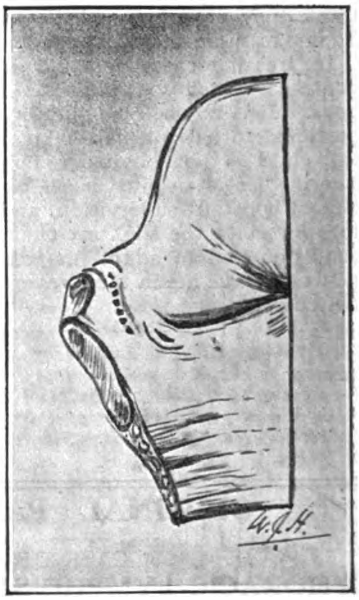
growth in the posterior mediastinum was 70 mm. There was some dilatation of the œsophagus above at the level of the bifurcation of the trachea. Both pulmonary veins were surrounded by the growth, the right bronchus, although not invaded, was considerably narrowed. There was a direct extension of the growth into the lower lobe of the right lung. There was much surgical emphysema round the root of the right lung, and also between the chest and the pleura; the lungs were somewhat collapsed, but presented no further evidence of disease.



A photograph taken from behind to show the invasion of the posterior mediastinum by the new growth. The structures entering into the photograph from left to right are:—(1) The inner portion of the left lung. (2) The descending aorta. (3) The œsophagus laid open to display that portion of the growth which bulges into, and almost obliterates, the lumen to the extent of 115 mm. The walls of the œsophagus are separated by a glass rod inserted in the upper part at a level corresponding to that of the bifurcation of the trachea. The œsophagus above this level is dilated. (4) The main portion of the growth outside the œsophagus, and to the right of the middle line. (5) The inner portion of the right lung showing the direct extension of the growth into the lower lobe.

Microscopic examination of the growth showed it to be a round-celled sarcoma.

The larynx presented, over the right arytenoid region, a circumscribed area of œdema, about the size of a raisin. On the inner aspect of the right arytenoid there was the puckered scar of an abrasion, situated in the fold of mucous membrane passing down between the cartilages of Santorini and Wrisberg, a site which I have described elsewhere as one lending itself to systemic infection, and which I have termed the vulnerable spot in the larynx (*a*). It is indicated in the accompanying diagram by a dotted line, and must be distinguished from the common site of a tuberculous ulcer, which is immediately behind and a little below the vocal process (the posterior sesamoid cartilage) of the vocal cord. There was no marked enlargement of the cervical lymphatic glands.



A diagram of the interior of the left half of a larynx to show the site referred to as the *vulnerable spot*, which is indicated by a dotted line.

The case presents some unusual features of clinical and pathological importance:

(1) The extent of the occlusion of the lumen of the œsophagus by an extrinsic new growth.

(2) The possibility of passing a bougie of the largest size, in spite of such marked œsophageal obstruction, illustrates both a clinical fallacy, which may attend the use of soft rubber instruments, and also the value of œsophagoscopy in the diagnosis of such cases; it being improbable that a rigid tube would have passed the growth.

(3) The localised œdema of the larynx might be accounted for by the conditions within the thorax. At the same time it is as well to consider the possibility of such œdema being occasioned

---

(*a*) Introductory Paper to a discussion on "The Upper Respiratory Tract as a Source of Systemic Infection," British Medical Association, Annual Meeting, Swansea, 1903.

by a local infection at the site indicated. The presence of the scar in the larynx raises the interesting question whether the thoracic growth were not the result of an infection, and whether lympho-sarcoma may not eventually have to be numbered, together with the lesions met with in Hodgkin's disease, amongst the infective granulomata. The question is not necessarily negatived by the absence of enlarged cervical glands, for I have shown experimentally that after an inoculation the proximal group of glands may not be permanently affected. whilst *post-mortem* a distal group may be found markedly enlarged.

THE TREATMENT OF URINARY DISORDERS BY THE MINERAL WATER OF EVIAN.

By J. GRISEL, M.D.

Consulting Physician at Evian-les-Bains, France.

From ancient records it would seem that from the earliest times the mineral waters of Evian were used for gout, nephritic colic, gravel, and other urinary disorders. In fact the first account of a recovery due to the drinking of this water concerns a certain Baron de la Rochette, who was thus cured of gout in the fifteenth century. It is not until the end of the eighteenth and at the beginning of the nineteenth centuries that treatment of the Evian Spa was regularly applied, after the testimony of Tingry, a professor of chemistry at the University of Geneva (*a*). There were then sent to the Spa people suffering from "irritative diseases." For a long time gout and other unhealthy conditions of the urinary tract mostly brought sufferers to this spa: among them many patients affected with catarrh of the bladder, urethritis or gravel were to be seen. Even now the physicians who have been practising at Evian for a tolerably long while, can recall more than one stricture of the urethra treated there. The use of this pure water, with its accompanying mineral qualities, in such a state of dilution is, that its passage through the kidneys and urinary organs effects a regular flushing and sedative action, and proves highly beneficial to many patients of this class.

Of course the peculiar property of the water, resulting from its quick passage and rapid elimination, would make it unavailing and even injurious for people in whose urinary tract there is an obstacle to the free discharge of the urine—*e.g.*, big renal calculi, excessive hypertrophy of the prostate—especially of the median lobe—or a tight stricture of the urethra. Such patients should entirely abstain from the water, or be sent to Evian only when the obstacle is removed by means of an operation designed either to destroy the calculi or to remove the stricture, &c. (*b*) Then not only will they be able to make use of the water without inconvenience, but it will be a duty for the medical men, under whose care they are, to prescribe it, when they become aware of the benefit that their patients will derive therefrom. Under its influence the inflammatory symptoms disappear, the general nutrition is improved, and in most cases relief speedily ensues.

Is it possible to discriminate, *à priori*, between the patients who can be sent directly to this spa and those who need preparatory treatment or operation? This question finds its solution in the statement of a precise diagnosis, the elements of which we have not here to deal with. It ought, however, to be pointed out, among the latest processes of investigation, that cystoscopy, and the examination of the urine of each kidney, obtained separately with the help of Cathelin's or other "*diviseur*," would generally reveal the true state of affairs. Above all, in order to make out, as far as possible, the position and size of the calculi, it may prove useful to resort to the X-ray examination and to radiography, especially in the case of very obese persons, with the use of a compression cylinder (*a*).

Dr. O. Kraus, of Carlsbad, asserts that the biggest calculi he ever saw eliminated in an attack of nephritic colics were about the size of an almond (*b*). From another point of view the shape of the calculi is of considerable importance as to the ease or difficulty of their going out of the pelvis and down the ureter. I have before me an opuscule written by Dr. Rafin, of Lyons, relating to "renal calculi and radiography," in which some samples of stones were radiographed—first, when still in the kidneys, and then after their removal by nephrotomy; it is easy to understand that some of these concretions, in spite of their small size, would have produced severe pain when passing through the ureter, on account of the sharp points and edges that are spread all over their surface (*c*).

It will, therefore, be well to remember that the largest stones *do not*, in every instance, give rise *in situ* to the most obvious symptoms, and that, not uncommonly, gravel, and even tolerably big calculi can be passed through the ureter without acute pain. In such cases stones are often only noticed when, having reached the bladder, they cause evident disorder. How often does the renal lithiasis remain concealed, some pain or even a mere weight in the loins being noticeable, until pyelitis, or renewed hæmaturia, awake the practitioner's perspicacity!

Perhaps, by resorting more frequently to Röntgen rays, it will be possible, in many a case (*d*), to trace back to their real cause some symptoms of which the interpretation is puzzling, and therefore to infer more speedily the right mode of dealing with the disease.

But here, as everywhere in medicine, we shall probably prevent rather than cure, and attempt to stop the production and the increase of calculi by prescribing the use of the mineral water of Evian, the efficacy of which is testified by many years, not to say centuries, of experience. It is indeed the results of the latter, supported by the investigations and work of the medical profession on the spot, that Professor Landouzy summed up, when he observed (*e*) that the ingestion of the water of Evian, opportunely

---

(*a*) An analysis of the mineral soapy (alkaline) waters of Evian, Geneva, 1808.

(*b*) Should they be sent here, however, suffering from acute conditions, they require the greatest care during the treatment in order to obviate, as far as possible any untoward effect.

(*a*) Dr. Arclin, from Lyons, uses, instead of a cylinder, a rubber balloon applied to the abdomen by means of a strap, at each end of which is hanging a bag filled with sand (or any other material), as much as is necessary to exert a compression sufficient to keep the wall and the kidney motionless.

(*b*) The *Lancet* No. 4366, May 4th, 1907, p. 1222.

(*c*) Dr. M. Rafin, communication à la dixième session de l'association Francaise d'urologie.—Evreux Hérisy et fils, 1906.

(*d*) As far as we can imagine from what we know of X-rays, it is possible to suppose that, in the actual state of their application, not all kinds of calculi can be revealed, those composed, partly or wholly, of lime salts will be most readily made out.

(*e*) Lecture delivered at Evian, September 12th, 1901.

prescribed, is the best plan we can conceive to modify the cellular and visceral nutritions, and to flush the urinary tract of patients affected with a catarrh of the bladder, ureters or kidneys.

SOME POINTS IN THE PROBLEM OF

ILL-HEALTH AND SCHOOL ATTENDANCE. (a)

By F. J. POYNTON, M.D., F.R.C.P.Lond.

Physician to Out-Patients at the Hospital for Sick Children, Great Ormond Street, and Assistant Physician to University College Hospital, London.

With regard to infectious diseases, I shall be content to echo a sentence in Dr. Kerr's report for 1905–1906, p. 30, to this effect :—" The time has come to press on the Board of Education the necessity for allowing the Epidemic Grant as a natural insurance against the school diffusion of disease, and as a means of allowing sufficient prolongation of the convalescent period when children have been suffering from infectious diseases."

This mention of infectious diseases leads to the question of sore throat. We know that the first symptom of such important diseases as diphtheria, scarlet fever, measles, mumps, and rheumatic fever may be a sore throat. How alive the London County Council have become to this danger in the case of diphtheria is clearly shown in their resolution to the effect that during the presence of diphtheria in any district readmission is refused to children who have been excluded on account of sore throat or diphtheria, until they have obtained a medical certificate of freedom from infection based on a bacteriological examination. But what is to be done with a child who comes to a doctor with a sore throat when there is not an outbreak of diphtheria? The bacteriological examination cannot by any means always tell us the meaning of that sore throat, and inspection is also often not sufficient. It may be a passing tonsillitis or a commencing scarlet fever. The child may be practically harmless or a virulent focus of infection, and yet the decision at first may be impossible. I am of opinion that all cases of sore throat which come to the knowledge of medical men should be excluded by a certificate from school attendance until they are well, and that school teachers should be particularly watchful for complaints of sore throat and not hesitate to bring such cases at once for inspection. I admit the danger of the abuse of this precaution by unprincipled parents, but it is a lesser of the two evils, and medical men will not, I think, be often outwitted by sore throats. Epidemics will be more easily dealt with, and more rapidly stamped out if the danger of a sore throat in childhood is clearly recognised.

A sore throat may be the first symptom of acute rheumatism or rheumatic fever, and leads me to consider next this important disease. So far as my own contribution to the discussion is concerned, it is upon this subject that I most hope to be of some assistance.

The general public are but little aware of the frequency and severity of this disease in childhood. They associate acute rheumatism with painful and swollen joints in adult life, and speaking vaguely of acidity in the blood do not realise that the disease is the result of an infection by a micro-organism and that many important organs other than the joints are frequently damaged. Should any here be in doubt as to my meaning, I would ask them to compare rheumatism to tuberculosis. Tuberculosis may attack many organs. The most familiar condition is tuberculosis of the lungs, but there may be tuberculosis of the joints, or brain, or alimentary canal. So, too, with rheumatism, there may be rheumatism of the joints, rheumatism of the heart, rheumatism of the brain, and so on.

In childhood this disease often attacks many organs, and two may be mentioned as of first importance—the heart and brain. Rheumatism is the great cause of heart disease in childhood, and it is also the great cause of chorea or St. Vitus's dance.

Dr. Newsholme some years ago pointed out that acute rheumatism was essentially an urban disease, and in London it is particularly frequent, and it is common in all large towns. This disease is strongly hereditary, and one believes this to mean that the children of rheumatic parentage have transmitted to them a delicacy of tissues which makes them especially susceptible to the rheumatic infection. The problem of rheumatism and school attendance presents several aspects. The first of these is concerned with the children of rheumatic parentage. It is an observation of general acceptance among medical men that such children are often highly nervous and subject to night terrors and headaches, and that they easily get over-excited and over-tired. They derive much good from school discipline, but when they begin to dream about their school-work at night and worry over their lessons, no children more certainly need rest and relief from mental exertion.

The next consideration is a much more urgent one, for it is concerned with the proper treatment of those children, whether of rheumatic parentage or not, who develop an attack of acute rheumatism. If the joints are affected then the pain and incapacity for movement at once renders school attendance impossible. When, on the other hand, the heart or the brain is affected—structures of incomparably greater importance—strange though it may seem, I continually meet with the fact that these children have been attending school until there is a complete breakdown. Yet no rule in medicine is probably more assured than that which lays down rest in bed as an essential treatment for acute rheumatism. How is it then that active heart and brain rheumatism are so easily overlooked? The reasons are two, the first is that their early warnings are often very indefinite, the other is that there is not a general knowledge of the fact that the conditions are rheumatic. Early heart disease is singularly free from pain, and on this account pallor, lassitude and shortness of breath are not given their due importance; vague pains are, peharps, called growing pains, and the absence of swelling of the joints tends to dispel all suspicion of rheumatism. The headaches, irritability, and irregular movements of early chorea are put down to naughtiness or carelessness, and the impossibility of fixing attention is attributed to wilful disobedience. Then those attendance medals which, from my point of view, appear to be so injurious, stimulate the child himself to hold on until compelled by illness to give up. Valuable time—invaluable time, in fact—is thus lost, for it may be asserted that though the majority of children *recover* from an attack of heart rheumatism, few escape without some *permanent damage* to the valves of the heart. Again, as I have remarked, rheumatism in childhood often affects many organs at the same time, and so it comes about that many cases of brain rheumatism or chorea, are also suffering at the same time from heart rheumatism. How can these difficulties be dealt with? No sudden or sweeping measures will succeed, I think, but there must be a gradual education of the general public to the recognition of the frequency and meaning of active rheumatism in children, and I hold it of great importance that school teachers, especially, should be acquainted with its chief dangers. They have the power of doing both children and doctors a great service by thus helping to solve what is one of the greatest problems of disease in this country—the arrest of the vast amount of organic heart disease of rheumatic origin. Much of the heart disease of adult life, let me add, dates from rheumatism in childhood.

The third difficulty in this problem of rheumatism and school attendance is the great tendency there is for rheumatism to relapse. It is a common experience in London for a child of six years of age to be attacked with rheumatism, and from that time forward to suffer repeatedly from relapses now it is brain rheumatism, now cardiac rheumatism, now joint rheumatism. The recoveries, especially from cardiac and brain rheumatism are very slow, and the cases of chorea are so numerous that hospitals cannot cope with them, and yet when they are in the convalescent stage their home-life is often unsuitable, and school attendance is quite out of the question. We need in this country some of our great philanthropists to found convalescent homes where the rheumatic children might thoroughly rest and if they only knew the sadness of children's rheumatism I am positive those homes would soon be founded.

(a) Paper read at the International Congress on School Hygiene, London, July, 1907.

The last point for consideration in rheumatism is the child with heart disease. By this I mean the child who has recovered from the acute rheumatic lesion but is left with a heart more or less damaged. These children must be educated, but they are delicate and need careful management. The disturbance of the circulation of the brain by the heart disease often makes them nervous, and cold bitter weather and long flights of stairs are most obnoxious. It is evident that no routine school attendance is permissible, and so far as possible these cases should be singled out and special arrangements made for them.

To summarise these remarks upon rheumatism and school attendance, there are four main considerations :—(1) The excitable nature of the child of rheumatic parentage ; (2) The danger of active rheumatism when untreated by rest ; (3) The stubborn and relapsing character of the disease ; (4) The delicacy of children left with chronic heart disease.

Should there be any here who think that I exaggerate the great importance of rheumatism, I need only add that if they spent one week in making the round of our large London hospitals and infirmaries they would be astounded at the answers they would receive as to the frequency and severity of this scourge. In seven years as an out-patient physician, attending twice a week at only one of the children's hospitals, I have made notes of over 500 cases in children under twelve years and have seen quite as many more.

In passing I would mention a small group of children who are born with malformed hearts and who live to grow up to adult life. These need also most careful supervision during school life and must be grouped with the victims of acquired heart disease.

Leaving heart disease I would next direct your attention to a considerable group of cases of chronic lung disease which are not tubercular. Such, for example, as asthmatics, who are often most intelligent children. Those again who have suffered from severe pneumonia and bronchitis. Many of these among the well-to-do should not be permitted to winter in England. They are delicate, and during inclement weather want supervision, but a considerable number would recover completely, I think, with more care as to their school attendance.

Kidney disease again, often a heritage of scarlet fever, is a very important condition. It is certain that if a child who has suffered from the acute disease is—from insufficient care—allowed to drift into a state of chronic kidney disease, there can be only one end—viz., persistent ill-health and early death. School attendance must then often be very imperfect until the danger of a relapse has been thoroughly warded off, and yet the ordinary observer could detect nothing amiss during this time of convalescence. Only a medical man can accurately judge the stage of convalescence. There are seasons, too, which are most dangerous to those who have had kidney disease, and I have never seen a better example of this than in last April, when there was an extraordinary increase of acute kidney disease. During such times much judgment is required as to school attendance of a child who has suffered from renal disease.

A well-organised system of medical certificates and a greater development of schools for the physically defective are two precautions of first importance in dealing with these victims of rheumatic, cardiac, pulmonary and renal disease.

I would venture to suggest (paradoxically) it may seem that in these days of specialism medical men are not sufficiently aware of these special schools, and I think something might be done by the school authorities to make them more known. We ought, I admit, to be well acquainted with them, but we are so engrossed in our own heavy duties that we need to have their existence impressed upon us. They have been a revelation to me, and I am full of admiration for the splendid work they are doing. Yet I realise that they are very expensive, and that their multiplication must mean time and money. At present, too, I think, that though a recommendation from the medical man or hospital physician should be encouraged and welcomed, the ultimate decision of admission of a child to such a school should rest with the medical officers of the school board, because, in my opinion, they alone at the present time can decide the essential point as to whether the particular case is the most suitable among the many claimants for the limited accommodation now available.

Medical certificates will need to be as brief as possible. I can assure the Education Department that they can hardly realise the labour of a modern hospital outpatient department, with its enormous numbers, its school and vaccination certificates, its letter to be signed for convalescent homes (some of which are cruelly exacting), and its teaching duties. When I say that in a morning between seventy-five and one hundred medical cases may have to be dealt with in one department at a large children's hospital, some here may understand how worrying it is to have to turn even for a moment from the actual medical work.

EPILEPTIC CHILDREN.

The next class of cases to be touched upon is a most difficult one, and this is the epileptic. It is particularly difficult because there are two separate problems. One is, that of the actual fit, the other the mental condition between whiles. The severe fits are most distressing, and are most alarming to other children. Their occurrence during a class must of necessity upset everyone. Clearly a child who is suffering from repeated severe fits should not be attending an ordinary school. Experience, however, shows that we have all grades and varieties of attacks. In a collection of about 200 cases kindly made for me by my assistants, Drs. Moon, Brincker, Sweet and Crampton, this fact is well illustrated. Among them there are a number of children who only exceptionally have attacks—once in two months, for example. Many of these are quite intelligent, and if it were not for the alarming character of an epileptic attack they would be to all intents normal children. Then there are others who have infrequent attacks, too, occurring only at night, and then for some mysterious reason suffer from storms in which forty or fifty fits may occur in a week. Others, again, steadily improve under treatment. It is then evident that even if we consider the fits alone that no single rule can be laid down for the education of these children.

The other problem concerned with epilepsy is the mental state. This also varies greatly. As a general rule, it may be said, that the occurrence of many fits, whether of the severe or mild type, will in the course of time greatly damage the mind. It is, however, equally true, that some cases degenerate much more rapidly than others, and that mental failure may sometimes follow rapidly upon the occurrence of one or two attacks. The mental degeneration associated with epilepsy is a very serious one, and the imbecility of a dangerous type ; and with regard to the mental question I should be much interested to hear from some of those who take part in this discussion the general experience of school authorities in dealing with the education of epileptic children.

In addition to the damaging effect of repeated epileptic attacks on the brain, there are the strange mental states that sometimes follow immediately upon the fit and which are transient. The most dangerous of these is mania, a condition which, in adults, has been the cause of the most horrible murders sometimes of a wholesale description. Children, though they generally sleep heavily or remain quiet after a severe fit, may also sometimes do extraordinary things and be, for a while, quite dangerous to those near them. One boy under my observation ran away from home time after time immediately after a fit.

Personal experience of epileptic children leads me to think that, from the educational point of view, we *cannot* group them into two great classes. From the standpoint of convenience this would be a simple measure, for the slight cases would attend school and the severe would go to an epileptic colony, but I feel convinced we should not have done our best, for there would be a large number left not able to attend school with regularity, and not suited for a colony. These would run a great risk of becoming uneducated, a deplorable event, when we bear in mind that even bad cases may get quite well under steady treatment and with others the fits be greatly curtailed. In dealing with this problem, I see the brightest light in an intelligent co-operation between parents, school teachers and medical men, coupled with the cautious trial of special schools for the large class of epileptics that lie between the very mild and very severe types. Deficient children form a very large class in big towns, and with many types of these I cannot attempt to deal.

I would most briefly allude to certain common conditions among the poor, which may at first sight seem somewhat trivial, but which through the ignorance and, I might even say, the degenerate carelessness of many parents are productive of great harm. These are neglected teeth, chronic ear discharges and adenoids. The teeth of poor children are horribly neglected, and the tender and offensive conditions of their mouths and gums produce dyspepsia from food bolting and anæmia from continual poisoning. Some homely instruction upon this point and some practical illustrations of the use of the tooth-brush would be as useful as any physical drill.

Chronic ear discharges are a danger to the child and an offence to its associates, and it is deplorable how callous parents are upon this point. Adenoids, by blocking the nasal passages, are the cause of much stupidity among children. It is, in fact, impossible for a child to keep his attention when the condition is severe. Few people, I think, who are fixing their attention do so with their mouths open, but these children cannot breathe if their mouths are closed. Respiration is impaired, and the blood not thoroughly cleansed, the chest becomes deformed, and middle ear disease and deafness are constant occurrences in the victims of adenoids. These cases should be properly treated and responsibilities of the parents aroused.

The last group I mention is a very large one, and it can, I think, only be dealt with by skilful and gradual organisation. Many children, naturally robust, become, particularly in the summer, pale, languid, irritable, and highly nervous. No actual disease is discovered, though some enlarged glands in the neck may raise a suspicion of early tuberculosis. Among the more well-to-do such children are promptly sent to a bracing seaside or inland resort, and lessons stopped or reduced to a minimum. Poor children cannot be got away like this and are often in a worse plight at home than they are at school. Yet we cannot escape from the fact that many severe illnesses result from the neglect of this early sign of failure of health, and that it would be a great step forward if some scheme could be gradually evolved by which these cases could be drafted to country or seaside convalescent homes in touch with country schools. An organisation of a system of convalescent homes would be required, and the whole undertaking would need the greatest caution and watchfulness in order to prevent the immediate abuse that would spring up as surely as it has in our hospitals. The present splendid effort of the Lord Mayor of London on behalf of the cripple children is an encouragement to hope for some further steps in the direction of that true education which strives to preserve the *mens sana in corpore sano.*

THE OUT-PATIENTS' ROOM.

FRENCH HOSPITAL, LONDON.

Columnar Carcinoma.

White Swelling at the Wrist.

BY A. D. KENNARD, F.R.C.S. (ED.)

AMONGST Dr. Vintra's out-patients was a man, æt. 52, who came up with a history of five weeks' slight pain in the lower part of the abdomen, and constipation, alternating with diarrhœa, and the passage of blood and mucus. He had been getting thinner for the last four or five months. No history of vomiting, though he suffered from nausea. On examination, patient had a cachetic appearance; he was not at all emaciated. The heart and lungs were normal, and liver was not enlarged. Urine, Sp. gr. 1015, contained a little albumen, but no other abnormal constituents. On rectal examination a hard ulcerating tumour could be felt about 2½ inches above the anal aperture, it admitted the passage of a finger with difficulty, and completely surrounded the bowel, and was firmly fixed to the surrounding tissues. It was, in fact, an advanced case of columnar carcinoma.

Treatment.—Patient was given a weak permanganate lotion to use as an enema every morning, and a laxative to keep the bowels open.

Remarks.—This case was in a very advanced condition, and was quite inoperable, and showed how very few symptoms accompany carcinoma of the rectum in the majority of cases. If the patient had been seen earlier it would have been quite easy to remove the tumour, as the growth was quite low down. The only question that remained was that of a colotomy, and I am in favour of delaying this operation to the very last, in fact until the symptoms of oncoming obstruction present themselves.

A woman, æt. 30, single, came up with a history of pain and swelling in the right wrist, of two months duration, caused, she thought, by lifting a pail of water. She said she had been quite healthy, except for an occasional cough. On examination, the wrist presented the familiar appearance called by the name of "white swelling." Anteriorly there is thickening along the tendon sheath, and behind a certain amount of ill-defined fluctuation could be felt. There is a loss of mobility in the wrist and there was some pain on manipulation.

On examination of the chest there was found to be diminished expansion and a certain amount of dulness at the left apex with prolonged expiration, but no râles were present.

Treatment.—The forearm was put upon a splint, and the wrist dressed wiith Scott's ointment. She was given an emulsion of cod liver oil, to take three times a day.

Koch's New Tuberculin 1–5000 of a milligramme was injected into the gluteal region, and the patient told to remain in bed for twenty-four hours.

Remarks.—This case was one of tuberculous disease of the wrist joint, with a patch of old phthisis at the left apex. These cases nearly all do well with small injections of tuberculin once a fortnight; it is advisable to take the opsonic index, but if very small doses are given, and the duration between the injections kept at about fifteen days, this was not absolutely necessary. I believe that keeping the patient in bed for twenty-four hours after the injection is of great benefit in the treatment of these cases.

THE will of Dr. Alfred Square Cooke, M.R.C.S.Eng. L.S.A.Lond., of Stroud, Gloucestershire, for thirty-seven years medical officer at the Stroud Workhouse, who died June 1st, has been proved by the widow and sole executrix, Mrs. Margaret Cooke, at £1.705 18s 7d

OPERATING THEATRES.

GREAT NORTHERN HOSPITAL.

Fracture of the Lower End of the Humerus: Wiring.—Mr. **Arthur Edmunds** operated on a child, æt. 5, who had been admitted suffering from a fracture in the lower end of the humerus in the neighbourhood of the epiphysial line, the result of a fall. An X-ray demonstrated the fact that the shaft of the humerus was displaced anteriorly to the lower fragment, so that when the limb was flexed with the deformity unreduced, the bones of the forearm came into contact with the lower end of the upper fragment, preventing effectually a permanent flexion of the arm beyond a right angle. An attempt was made to manipulate the fragments into position, but this was found to be impossible, and accordingly an incision was made through the lower third of the triceps right down to the bone. The fascial attachments of the lower end of this muscle were stripped slightly to each side, so as to give access to the seat of the fracture. A periosteum detacher was then thrust forwards and downwards between the two fragments, and in this way they were lowered into position. When once in position they showed little tendency to displacement, but, in order further to steady them, a wire was passed through the outer condyle, and then carried up to a point above, and internal to it on the shaft, just clearing the olecranon and the coronoid fossæ. When the ends of the wire had been twisted up it seemed to steady the bone quite effectively, therefore no further wire was put in. All bleeding points were carefully arrested, and the muscular layer was just drawn together with a few catgut sutures. The skin wound was closed without drainage. Mr. Edmunds said that cases of fracture of the lower end of the humerus, especially in children, were amongst the most difficult fractures to deal with. They frequently involved through part of their extent to epiphysial line, but the line of fracture was pretty certain to extend into the shaft of the bone or the epiphysis. It was very difficult, he pointed out, to be perfectly certain by digital examination that accurate apposition of the fragments had been obtained, and these fractures should always be most carefully examined by stereoscopic skiagrams to see how far the attempts at manipulation had been successful. If the fragments can be manipulated into position by traction upon the flexed forearm, it was usually possible, he remarked, to maintain the reduction, the arm being put up at an acute angle, about 60°, but when, as in the present case, this cannot be done, an operation should be undertaken as soon after the injury as possible, for any imperfections of the joint surfaces lead to the greatest impairment of the joint. After wiring, Mr. Edmunds said, it was frequently found when the wound had healed that movement was not as perfect as it was at the actual moment of operation, but this difficulty was often unavoidable, as it was produced by the callus which formed about the line of fracture; this callus, however, rapidly disappears, and the movements of the joint become perfectly normal. It was rare, he asserted, that the surgeon has to operate on children under four, as in these cases reduction can nearly always be obtained. Above this age operation was very frequently necessary. Whatever method of reduction was adopted, the after-treatment, he remarked, was about the same: the arm should be put up at an acute angle; the object of this was, that at the time of the reduction it was usually possible to place the arm in any position the surgeon may desire, but a certain amount of limitation of movement always occurred, at any rate temporarily. A limb which can only move through an angle of 60°, starting at the fully extended position, was practically useless, and the patient had no inducement to use the arm, and so by the ordinary movements of every-day life increase this range. A range of movement, however, of exactly the same extent, but extending from 30° on one side of the right angle to a position of 30° on the other side of the right angle left the arm for all practical purposes perfect; the patient can use the limb freely, and by so doing would inevitably increase this range until the full flexion and extension could be obtained; for this reason the acute position should always be employed, affording, as it does, not only a more satisfactory maintenance of the fragments in position, but also an earlier utility of the limb.

The Method of Bier.

Bier's method on passive hyperæmic stagnation tends more and more to take an important place in therapeutics. Passive hyperæmia is obtained in two ways—either by provoking the sanguine stagnation in the whole of the limb or by localising it to the affected region.

In the first case, an indiarubber band is wound round the root of the limb; in the second, an apparatus is used from which the air is exhausted by means of an aspirator or an elastic syphon. The bandages employed by Dr. Delagenière (a French authority on the subject) are made of soft indiarubber, varying in width according to the region treated—three inches for the thigh, two for the arm, and half an inch for the fingers.

The application of the band is the delicate point in the treatment and requires a certain experience to produce the desired constriction.

The arterial circulation must in no way be impeded, while the venous circulation should, on the contrary, be arrested in order to produce hyperæmia. This rule, being always kept in mind, the bandage is applied to the root of the limb, each turn covering the previous one and the caoutchouc slightly stretched so as to obtain the desired constriction by the elasticity of the band and the ends tied in a knot or, as Klapp recommends, simply welted and applied exactly, at the point of termination.

Immediately after application, the skin becomes congested, the veins turgescent, and the limb takes on a violet colour. If the patient complains of a feeling of numbness in the limb, the constriction is too tight, the band must be removed, and applied again, for in no case should it cause suffering.

When the band is well tolerated, it can be left on an hour, and the séance repeated several times a day. In case of acute inflammation, M. Delagenière leaves it on twenty or twenty-two hours a day; in such cases the constriction is not so tight, but the patient must be watched for fear of accidents.

When the séance is ended, the band is removed, when the violet colour of the skin disappears and gives place to a bright red coloration. The numbness caused by the constriction also disappears, and the patient experiences a *bien être* which lasts to the next application.

In certain regions (axillæ, neck, trunk, abdomen, inguinal regions) the band cannot be employed. It is in such cases that recourse is had to the apparatus already alluded to, of which the simplest kind is the ordinary instrument for dry cupping, composed of a glass dome surmounted with an elastic ball by which the air is expelled; others are more complicated and require aspirators. With these apparatus, the séance should not last more than five minutes at a time, but should be frequently repeated.

The applications of Bier's method are very numerous. They render great service in cases of boils and anthrax, where the dry cup can arrest the non-suppurating boils in four or five days, while where suppuration has set in, a small incision is made with the bistoury and the dry cup applied, it withdraws the pus and produces a rapid cure.

Inflammatory abscesses and frequently cold abscesses after incision, whitlow, phlegmon, should be treated by long séances, but the band must be attended to as certain patients present a special susceptibility of the skin, recognised by phlyctenæ indicating that the constriction should cease.

Bier's method gives also excellent results in the treatment of abscess of the breast, acute or chronic. The same may be said of suppurating or non-suppurating ganglions. Each séance should last one hour.

In cases of crushed limbs, the band applied for one hour, twice a day, is very beneficial and frequently a whole limb or a part of it is preserved, which otherwise would have to be sacrificed.

In fractures, the consolidation is more rapid if the band is applied to the root of the limb for one hour every morning.

Osteitis osteo-myelitis, tuberculous osteitis, spina ventosa are very favourably influenced by this treatment.

The hyperæmic stagnation favours the absorption of articular effusions. In chronic hydrarthrosis, and in hæmorrhagic arthritis, it gives splendid results.

In acute tuberculous arthritis, the application of the band has a remarkable effect by diminishing rapidly the redness, the pain and the inflammatory phenomena.

Orchitis, treated by an indiarubber tube rolled around the scrotum, yields readily.

Such are the principal cases in which the Bier method is indicated. The mechanism of its action seems as yet somewhat mysterious, and the different theories proposed are not fully satisfactory. But there is one point on which it is necessary to insist—the application of the method requires training and a good deal of patience in order to arrive at good results.

INTERTRIGO IN THE ADULT.

The inguinal region is the favourite seat of intertrigo in the adult, and the cause is generally to be found in obesity.

Eau de Cologne, 6 ozs.
Tincture of iodine, 2 ozs.

Or,

Liquid saponified tar, 4 dr.
Eau de Cologne, 6 ozs.

Or,

Ichthyol, 2 dr.
Water, 4 ozs.

Applied as lotions.

Where the lesions are more aggravated, a solution of nitrate of silver (1—15) or permanganate of potash (1—2,000) might be employed, followed by an application of—

Oxide of zinc, 4 ozs.
Carbonate of bismuth, ½ dr.

Lanoline Vaseline	aa 4 dr.

In women, the intestrigo is complicated with intolerable itching of the vulva, with œdema. The following ointment renders service:—

Codol, Oxide of zinc	aa 1 dr..
Ichthyol, Resorcine	a a xv gr.
Vaseline Lanoline	a a 4 dr.

THE report of the medical officer for Leicester shows that the week produced only a single death from diarrhœa. In 1902 the corresponding week yielded but two.

GERMANY.

Berlin, Aug. 25th, 1907.

THE TREATMENT OF BACKWARD DISPLACEMENTS OF THE UTERUS.

AT the Hufeland Society Hr. Strassmann brought forward the subject: "When and in What Way are Backward Displacements of the Uterus to be Treated?" There were in Berlin, he said, 80,000 women with retroversio uteri. This displacement did not occur amongst the lower animals. The uterus in them was longer and reached to the kidney region; moreover the manner of walking on all-fours prevented its falling back. Without a doubt the upright position was the principal cause of the abnormality; there was also the width of the pelvis necessary for the passage of the head of the child. The human uterus developed in a certain position. The flexed anteversion was maintained bythe abdominal walls and increased by abdominal pressure. No flexion of the organ backwards occurred even after severe injuries, as the uterus was, considering its importance, the least protected organ in the body.

It might have a wrong position to begin with; retroversion was either congenital or acquired. The latter was the most frequent. The sixth part of backward displacements was congenital (in virgins and nulliparæ). A mechanical action was not excluded: 1. by the conventional over-distention of the bladder; this caused a softening and backward pressure of the part; 2. by the habitual overloading of the rectum. Both factors were in action in childbed. The ligaments of the uterus acted as a kind of stay. If the uterus once became displaced backwards further changes took place. The anterior vaginal wall became free and the bladder became more easily distended. Cystocele occurred and the anterior vaginal wall became depressed. The rectum also became distended, a rectocele formed and prolapse easily took place. The utero-sacral ligaments played but a small part. The cervix as a firm tube had also an importance as regarded position, as had also cicatricial changes of the portio vaginalis.

Consequences of the displacement. The broad ligaments embraced the uterus and these were responsible for many troubles. Twisting of the vessels took place, venous stasis followed, with the formation of varices. The posterior lip became thick and pale and not infrequently there was erosion; the anterior vaginal wall became thin. The uterus as a whole thickened and disturbances of menstruation showed themselves; it became more profuse with excretion of mucus in consequence of endometritis. Pains occurred when the mucus was expelled in virgins and nulliparæ. The displacement of the ovaries was also of importance. The follicular hæmatomata became larger from venous stagnation. An anticipating menstruation might take place, occasionally the formation of hæmatomata of the ovary might take place and, by transudation, small cysted degeneration of it. Fertility was often disturbed It might not cease as the flexed organ might become pregnant. In many cases, however, bleeding took place in the membranes, followed by abortion. The impeded gravidity was a result of the change of direction of the portio vaginalis.

Patients complained of a feeling of continuous pressure downwards. The vessels of the rectum were full and compressed, and the patients suffered from hæmorrhoids and reflex gastric troubles, although the tongue was clean; hysterical symptoms; in severe cases there may even be amaurosis and paralysis.

A large part of the troubles might undergo compensation by the body itself. The uterus could only become erect during pregnancy. Adhesions were formed by small extravasations of blood from the ovaries, etc. In secondary displacements no operative measures should be undertaken during the first year. In nine months most of the excitors of inflammation were dead. Later than that sterile pus was found. Here tamponnade and sitz baths were useful.

Treatment.—Not every case of retroflexion required operation. Where the symptoms were slight and the patient beyond the climacteric, operation might be dispensed with. There were a number of cases in which treatment by pessaries was sufficient (16 20%) these were cases without complications of laceration of the cervix or perineum.

Operation was reserved for those cases in which the uterus could not be brought into position otherwise. The speaker then discussed the various operations and expressed his preference for vaginal fixation.

Prophylaxis.—Nothing need be said about the congenital form. Every lying-in woman should be examined about the end of the third or beginning of the fourth week, if displaced the uterus should be put right and a pessary inserted. Too early getting up as some patients desired favoured the displacement.

AUSTRIA.

Vienna, Aug. 25th, 1907.

COLLUM ANATOMICUM HUMERI.

EISELBERG presented a patient at the Gesellschaft suffering from a fracture of the anatomical neck of the humerus in the left arm from a fall. Immediately after a very large hæmatoma formed on the inner side of the arm below the fracture. The pulse in the radial and cubital regions was imperceptible. He thought this a very good example for demonstrating the danger of gangrene from bandaging in fractures. He admonished careful vigilance of the pulse in the fractured extremity when applying a bandage for fracture.

PHOSPHORUS NECROSIS.

Teleky followed with a statistical account of the past and present incidence of this disease. In the Vienna hospitals at the present time this disease was very rare owing to the decadence of the match-making industry. During the last decennium the factory inspector had only 75 cases to report, while in the preceding period for the same time 400 were reported. Whatever the philosophy of the nature of the poisoning, one thing is agreed upon, that some ill-defined change takes place in the osseous system that leads to destruction.

The nature of the disease seems to be a contradiction of our therapeutic dogmas, that bones require phosphorus for their building and repair, for in the match works it is the bane of the industry whose operatives suffer from a friable state of the long bones, particularly of the arms, that spontaneous fracture often occurs amongst them.

This altered state of the bone leads to a low resisting power in purulent attacks that occur in the jaws where the bones are more exposed to the fumes. It seems that the purulent cell is first stimulated in the periosteum that succeeds the altered state of the bone by some metamorphoses in the nutrition which, when produced, allows the purulent cell to commence its destruction of the periosteum, and finally of the bone which depends on it for its support. Having once obtained a lodgment, its ravages extend to more remote portions of the body, more particularly to the brain, from which 20 per cent. of these patients die. The pus cell seems to be carried to the brain or some of its coverings, where a new centre of inflammation is produced, generally resulting in death.

The membrane of the eye is another portion of the body that the purulent cell attacks with violence, doing irreparable damage.

The therapy of this disease has not been a success, as we are as yet undecided on the primary cause. Conservative treatment is therefore the safest course in improving the hygienic condition of the operation.

Different countries have adopted different methods of manufacture for the same reason—one preferring yellow phosphorus, others white.

EXTIRPATION OF CARCINOMATOUS UTERUS.

This is an operation that one surgeon praises in youth, but as age advances can see very little benefit derived.

Veit records twenty of these operations without a death. Eighteen of these had uterus, ovaries, tubes and glands removed, the other two had the vagina removed as well after Freund's advice, but he thinks Wertheim's technique better. With the use of spinal anæsthesia he has no scruples about heart failure, which is always a grave concern when chloroform is used. The results are much better when no chloroform is used. Veit tells us that too much is made of the surroundings containing the carcinomatous germs, but there is no such virulence to be dreaded if the parts be kept clean of the cancerous surface, and the abdomen kept dry afterwards.

PANCREATIC REACTION IN URINE.

Eichler has been experimenting with Cammidge's test for the pancreatic reaction in the urine as a diagnostic test for the disease. Cammidge found that when Phenyl hydrazin was added to the urine of a patient suffering from pancreatic disease, a white or bright yellow precipitate was formed. This was supposed to be the result of some fatty necrosis. Eichler fermented the pancreatic secretion, and split up the fluid into a fatty acid and glycerine. The glycerine was separated from the urine by boiling with HCl., and converting it into glycerose, which afterwards admitted of the Phenyl hydrazin test. Three dogs were next affected with the pancreatic disease, the urine tested with a positive result, while the control of healthy dogs' urine was negative.

CONTINENTAL HEALTH RESORTS

[FROM OUR SPECIAL CORRESPONDENT.]

CHATEL-GUYON.

CHATEL-GUYON is justly entitled to a high position amongst Continental Health Stations, because of its readiness of access from our shores, its pleasant surroundings (interesting alike to artist, scientist, and antiquarian), its good Bath and hotel accommodation, its talented medical staff, granitic dry soil, pure and light atmosphere, and, above all, the excellence of its mineral springs. Particularly, its waters are most important for treatment of intestinal, stomachic, and liver diseases.

Situated in the Department of Puy-de-Dome (part of the historic Province of Auvergne), its location is the very centre of France.

Southerly and Easterly it overlooks the vast plain of Limagne; Northerly and Westerly, it is shielded by the Auvergne mountain-chain. September is its desirable month for British visitors; "*the Season*" prolonging itself pleasantly through October.

As at the neighbouring Spas of Bourboule, Mont. Dore, and Royat, remains here attest the knowledge and use of Chatel-Guyon mineral-waters by the Romans. The present Bath-Establishments (the "*Grands Thermes*" and "*l'etablissement Henry*") contain:—

Baths with running mineral-water at the natural temperature of 28° and 34° Centigrade;

Baths with standing mineral-water at any temperature required;

Baths with more or less concentrated mineral-water at any prescribed strength and heat;

Baths of medicated waters, vapour, hot-air, douches, massages, local lavages, &c.

The electro-therapic installation is up-to-date and complete for electro-intestinal lavages, hydro-electric baths, carbonic-acid baths, vibratory massages, and continuous-current baths.

The Twenty-seven Mineral Springs emerge at the junction of the primary rock (extraordinarily hard red porphyric quartz) with the tertiary Limagne soil. They yield over five million litres every twenty-four hours; the whole enormous flow being absolutely protected from the slightest possibility of contamination or admixture in the passage from the primitive rock to the concrete-lined cast-iron reservoirs.

The analyses of the different Springs are almost identical, and are thus given by three distinguished chemists:—

Chlorides: Magnesium, 1.563; sodium, 1.633.

Bicarbonates: Lime, 2.176; soda, 0.955; iron, 0.685; lithia, 0.0194; potash, 0.2538.

Free Carbonic Acid, 1.112.
Sulphate of Lime, 0.5.
Only traces of Silica, Arsenic, Alumnia, &c.
Total per litre of water, 8.3986 *gr.*

At Chatel-Guyon these waters are employed in medicinal treatment both internally and externally. For internal purposes, five burettes are in the two Parks. Three, from the springs *Yvonne*, *Deval*, and *Germaine*, showing 33° to 36° Centigrade; and two, from Springs *Gubler IV.* and *Marguerite*, 26°. They are usually drank three times daily (one hour at least before each principal meal), and at intervals of several minutes. Their action, *immediate*, is tonic and stimulating to the nervous system; *secondary*, stimulative to the digestive functions; and later they affect the intestines. Digestion becomes more active and regular; urine passes more rapidly, plentifully, and thoroughly; gravel frequently occurs; uric acid (in gouty cases) first increases, then gradually disappears; phosphoric acid diminishes; urea and chlorides increase; albuminuria, if due to liver or digestive troubles, rapidly improves.

In the running-water baths, the temperature at *les grands Thermes* is 34°, and at the Henry Baths about 28° Centigrade; these temperatures being the natural ones.

The special feature of the external treatment at Chatel-Guyon is a Bath Carbogaseous, with freely-flowing Mineral-Water at its natural temperature, so conserving without any modification its richness in gas and in salts. Owing to the great copiousness of the Springs, 1,000 litres is frequently used in each daily bath; thus representing a dose of about 8 kilos of mineral-salts and 2,000 litres of carbonic-acid. Dr. Angelby therefore justly claims Chatel-Guyon unrivalled, in this respect, on the Continent.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

THE NEW HOSPITAL AT AYR ASYLUM.

THERE are several special features of the hospital which has recently been added to Ayr Asylum, to which attention may be usefully drawn. It is a substantial one-storeyed building, after the cottage hospital type, specially designed for the accommodation of those insane patients who are more appropriately treated in a building of hospital character, and the design gives effect to certain principles which, in the opinion of the medical superintendent, Dr. Easterbrook, should underlie the construction of a mental, as distinguished from an ordinary hospital, specially the principle of the treatment of active insanity by rest in bed in the open air, isolation, and other special measures for the alleviation of mental and nervous disorders. The design, it may be added, facilitates the work of the staff, which may in consequence be relatively smaller than usual; and so, while an efficient instrument for its purpose, is distinctly economical to administrate. Another important point is that owing mainly to the elimination from the design of everything which was considered superfluous, and notwithstanding the fact that the cottage-hospital type of structure is relatively expensive to build, the hospital at Ayr Asylum has cost, for total construction and fittings, £100 per bed, which is considerably less than the cost per bed of asylum hospitals hitherto. Efficiency for its purpose, low cost of original construction, and permanent saving in future expenditure on upkeep and administration, are cogent reasons at this time, when the public press is constantly harping on the cost of modern asylums and the ever-increasing burden of the lunacy of the country, for this descriptive note of the latest addition to our institutions for the treatment of the insane. Although the cost of this new hospital per bed is so much less than has before been considered reasonable, no detail appears to have been overlooked, the explanation being that while securing the means of efficient treatment, the medical superintendent was permitted to eliminate from the design everything that could be considered superfluous.

A COLOSSAL ENTERPRISE.—Notwithstanding the strenuous efforts of certain legislators and well-disposed temperance reformers in the direction of what is euphemistically styled, "the drink problem," more elaborate machinery and distilleries of greater capacity are still found to be needed, at least in the whisky trade. Last week there were opened in Glasgow the largest bonded stores of their kind in the world, which have been erected in Washington Street, by Messrs. James Buchanan and Co., the well-known whiskey distillers and blenders. Some idea of the extent of the buildings will be conveyed when it is mentioned that the site is as extensive as a large cricket field, and the warehousing capacity is 20,000 butts, representing a Government Revenue duty of £1,500,000. There are two blending vats of 20,000 gallons each, and nine others from 10,000 gallons downwards. In the blending department the contents of the vats reach the total of 70,000 gallons; whilst the contents of the vats for the bottling department are 30,000 gallons. In describing this colossal undertaking, the *Daily Telegraph* remarks that one week's work is equivalent to a pile of cases four deep, reaching to the height of Ben Nevis; and eight days would yield a stock of single cases as high as Mount Everest. A week's bottles laid end to end would be over fifty-three miles long. The employés engaged in the enterprise number over 650, and the Inland Revenue department is represented by two supervisors, each with a separate office, assisted by a staff of twenty officers.

BELFAST.

THE NOTIFICATION OF DEATHS FROM INFECTIOUS DISEASES.—During the sittings of the Health Commission, the question of the notification of deaths from infectious diseases, including tuberculosis, was under discussion several times, and as a result the Corporation applied to the Local Government Board to know the limits of their powers to expend money in obtaining such notification. The Board informed the Corporation that they had no statutory power to authorize such payments, and referred them to the Registrar-General as the official who could and should furnish the returns regarding such cases. The Public Health Committee applied to him, and hoped for a favourable reply, but have just had an answer regretting that he cannot give the returns to Belfast which in the case of Dublin he supplies to the local authorities each week. It appears that in the case of Belfast the material with which the Registrar-General deals is quite different from that which he receives from Dublin. In the latter city he receives full particulars, which are tabulated in his office, but from Belfast he receives only numerical returns, the tabulation being done by the local registrars. He could not, therefore, give full returns unless he had the full information to deal with, and even if the information were sent to him, with his present staff, he could not deal with it. He concludes with a sentence of interest to Dublin: "I beg to add that, as it appears from a letter from the Town Clerk of Dublin, printed on page 239 of the evidence given before the Belfast Health Commission, that of the lists of persons dying of infectious diseases furnished weekly to the Dublin Corporation from this department, the list of persons who have died from pulmonary tuberculosis 'is the only one which is really of advantage to the Corporation,' the question must now be considered whether the department should be put to the trouble and expense of furnishing information which is declared not to be of practical value."

IN Committee of the House of Commons on the Expiring Laws Continuance Bill, Mr. Lupton moved the omission of the Vaccination Act of 1898, because since the Act came into force cancer cases had increased by over 5,000 a year, which was due to the substitution of calf lymph for humanised lymph!

LETTERS TO THE EDITOR.

"THE USE OF COCAINE IN THE MORPHIA HABIT: A WARNING."

To the Editor of The Medical Press and Circular.

Sir,—During the past six months, I have had several morphia *habitués* under my care, who, on the advice of medical men, have taken cocaine with a view to curing themselves of the morphia habit. It cannot be too widely recognised that it is not only useless but in the highest degree dangerous to prescribe cocaine in these cases; it is true that cocaine does to a certain extent neutralize the effect of morphia, but this, in point of fact, is a disadvantage rather than a gain, as it merely tempts the patient to take larger doses of morphia and then balance the excess with a heavy dose of cocaine.

But the principal danger lies in the fact that such treatment inevitably produces the cocaine habit, by the side of which the morphia habit is comparatively insignificant; uncomplicated chronic morphinism is usually curable, but, when patients begin to take cocaine also, the difficulties of the situation are increased a hundredfold; not only is their immediate condition rendered worse by the advent of delusions and hallucinations, but their chance of ultimate cure is very much lessened, and relapses are much more common than in cases of simple morphinism.

The sudden withdrawal of cocaine leads to no actual distress or reflex disturbances such as occur in the case of morphia, and, when once patients know this, they are very apt to return to the cocaine, reassuring themselves meanwhile that they can break it off at any time without acute suffering.

In a fairly large experience of morphia cases, I have never seen a single cure expedited by the use of cocaine, and its dangers are so great as to make its recommendation quite unjustifiable.

I am, Sir, yours faithfully,
J. Henry Chaldecott.

Harley Street, W., August, 1907.

THE MEDICAL ASPECT OF DENTAL CARIES IN CHILDHOOD.

To the Editor of The Medical Press and Circular.

Sir,—It is very satisfactory to find that the medical profession at length has been brought to recognise the relation of dental disease to general pathology, and to note also that leading physicians, like Dr. G. F. Still, of King's College (whose paper appears in The Medical Press and Circular of August 14th) take occasion to bring forward and emphasise all the facts of practical importance bearing upon the question. One cannot help, further, feeling satisfaction at the knowledge that even in smaller country towns there is now usually to be found a properly qualified dental surgeon fully competent to co-operate with medical men in cases where special skill is needed. It is perhaps enough that the physician should recognise and act upon the fact that the teeth need taking into consideration as possibly the sole or contributory causes of systemic disease. It perhaps matters little if he has not a complete and correct acquaintance with the etiology and pathology of dental diseases. It would, however, save some mistakes, such as, I think, Dr. Still falls into, if some fundamental facts of dental physiology were fully understood and kept in view. One such fact is that enamel and dentine, when fully calcified, or when the process of their development has ended, are incapable of physiological activity. They are not the seat of malnutrition or of processes of atrophy or wasting, and any changes these tissues undergo after completion can be due to external agents alone. The exteriors of the crowns of all the temporary teeth are fully formed at birth; and these teeth can be influenced therefore only through the mother. By this time—at birth—the first permanent molars, incisors, and canines are so far advanced in development that it is more than doubtful whether treatment could have any effect upon their enamel. Rickets and all infantile diseases of malnutrition no doubt are associated with ill-made dental tissues, and, if the mothers could be taught and made able to maintain their own health during pregnancy, could be taught and made able to suckle their babies during the proper period, and if they could be taught and made able to feed them properly during childhood, much degeneration of developing dental tissue might be stopped, and much subsequent dental disease prevented. Imperfect formation and calcification of the tissues—especially enamel—constitute the chief predisposing cause of caries. Perfect enamel will endure almost any amount of neglect or ill-usage, but no amount of care will save teeth the tissues of which are easily damaged mechanically and easily dissolved by the weak acids, the product of fermenting particles of food, against the action of which it is impossible fully to guard them. In rickets and other such diseases there exist inherently defective tissues, whilst the constantly foul and vitiated secretions of the mouth which are always observable provide the agents by which the enamel and dentine are gradually penetrated at their weakest spots and more or less rapidly broken down.

I am, Sir, yours truly,
M.R.C.S., L.D.S.

London, W., August 25th, 1907.

MILK AND TUBERCULOSIS.

To the Editor of The Medical Press and Circular.

Sir,—Permit me to thank Dr. Granville Bantock for his reply to my query. That gentleman, after reading Dr. Armstrong's able summary of current knowledge on the above subject (The Medical Press and Circular, August 7th) nevertheless retains his attitude. It is, as I before remarked, Bantock *contra mundum*. He apparently denies all the demonstrated and easily-demonstrable facts leading up to the conclusion of the argument on the mere ground that it is impossible to trace out the origin of tuberculous infection, and to place one's finger on the exact source of contagion in particular instances. The possible sources of infection in the case of the cow asked for by Dr. Bantock, are named by Dr. Armstrong, and he states the fact which I also mentioned, that the long period of incubation in the human subject prevents, at present, determination of the source of the poison and the time of its reception. Dr. Bantock says I "accept statements not supported by any evidence." I reject his statements on precisely that ground. On the other hand, I accept the statements of bacteriological science with regard to tuberculosis, because I am satisfied that if I investigated the matter for myself I should arrive at the conclusions accepted by Dr. Armstrong and the vast majority of practical sanitarians. Dr. Armstrong accepts them, no doubt, like I, because he knows that the chain of facts has been proved by scores of independent workers in scores of pathological laboratories throughout the civilised world. Dr. Bantock has detached passages from Dr. Armstrong's paper which give a distorted view of the argument and conclusions. It is, of course, a demonstrated fact that malnutrition, and insanitary surroundings predispose to tuberculosis, as they do to many other diseases. These predisposing causes are being diminished, but it will be many years before they are eliminated. In the meantime, everyone—except, I suppose, Dr. Bantock—will take part in the endeavour to discover and destroy the sources of tubercular infection in every situation in which they are known to appear or suspected to exist.

I am, Sir, yours truly,
A Family Doctor.

August 22nd, 1907.

IS CANCER CURABLE?

To the Editor of the Medical Press and Circular.

Sir,—Having read the interesting report of the discussion on Cancer, I am tempted to ask the following questions: (1) Is cancer *curable* by operation? (2) What time must elapse from date of operation till patient is certified as *cured?* (3) Can the diagnosis of uterine cancer be *made to a certainty* by any means at our disposal, including the microscope ? (4) Cancer being a constitutional disease (somewhat like tubercle) how can the removal of its various manifestations arrest the disease for good, or prevent its showing itself again by metastasis ?—I am, Sir, yours truly,

Alexander Duke.

London, W., August 24th, 1907.

OBITUARY.

MAJOR HARRY FREDERICK WHITCHURCH, V.C., M.R.C.S., L.R.C.P.

We regret to announce the death, on August 17th, at Dharmsala, Punjab, of Major H. F. Whitchurch, V.C., of the Indian Medical Service. Born in 1866 in the Isle of Wight, he entered the Indian Army at the age of twenty-two, and took part in the Lushai Expedition, including the relief of Changsil and Aigal, for which he had the medal with clasp, and in the operations in Chitral in 1895, including the defence of the fort during its investment in March and April. For these operations he obtained mention in despatches, and was awarded the medal with clasp and the Victorian Cross for an act of conspicuous bravery in rescuing Captain Baird, who was wounded during a sortie from Chitral Fort. Major Whitchurch was also engaged in the campaign on the North-West Frontier of India in 1897-8, taking part in the defence of Malakand, the relief of Chakdara, the action of Landakai, and the operations in Bajaur and in the Mamund country, being again mentioned in despatches and receiving two clasps He also participated in the operations in China in 1900, when he was a third time mentioned, and was awarded the medal with clasp.

LABORATORY REPORTS.

ALLSOPP'S LAGER.

The reading of a paper at the recent meeting of the British Medical Association at Exeter on the subject of "alcohol" produced a somewhat heated discussion on the relative values and uses of this agent in the practice of medicine, light beers, such as are in common use in Germany, receiving commendation by several speakers.

In 1899, when Messrs. Allsopp first commenced the manufacture of lager beer in this country, we published an analysis and report on the same by Sir Charles Cameron, which plainly showed the excellence and purity of this lager. We have recently submitted samples of the beer to a fresh analysis, and have obtained results practically identical with those of Sir Charles. We find the beer to contain—

4.38 per cent. of extractives,
0.26 per cent. of mineral matter, and
4.06 per cent. of alcohol (by weight).

It is absolutely free from arsenic, while the flavour and aëration leave nothing to be desired. To produce beer of this purity, the materials used must necessarily be of the highest quality, which, together with the method and conditions of manufacture, allows the production of a beverage, which, in our opinion, is much to be preferred to the ordinary lager of German manufacture. We would commend this beer to the dyspeptic and debilitated, as a routine beverage on account of its low content of alcohol, and its tonic and stimulating properties. This lager can with confidence be recommended to patients where it is undesirable to prescribe other forms of alcohol, and its substitution for ordinary beer and whisky would, in the great majority of cases, be productive of nothing but good. The brewers claim many virtues for their beer, and so far as our experience goes, these claims are well justified.

LEMONADE.

The present summer weather has not so far been of such character as to necessitate frequent resort by "the thirsty soul" to the many tempting forms of lemonade put forward by manufacturers of this favourite yet harmless beverage. We have just had sent us for laboratory examination a granulated powder made by Messrs. Foster, Clark and Co., of Maidstone, called "Eiffel Tower Lemonade," which we have tested both chemically and practically, and find it to be what the manufacturers claim for it—a concentrated essence of the juice of lemons solidified and granulated. A strong recommendation to this form of manufacture, especially in large establishments such as hospitals, convalescent institutions, and the like, is its extreme simplicity. One has but to empty the powder into water with the necessary quantity of sugar, and the lemonade is ready to drink.

REVIEWS OF BOOKS.

COOPER'S RONTGEN RAYS. (*a*)

This is a well-written little book, intended to inform the general practitioner of the help he may get in practice from the Röntgen rays. The section upon renal calculus is especially clever, and gives the exact information that is wanted by those who are not experts in the art of radiography. The most popular part of the book will probably be that which deals with treatment. We are glad to see that Mr. Cooper recommends the practitioner who has only an occasional case of ringworm to treat to use the fractional method as against that of the single maximum dose, which is dangerous in any but skilled hands. The use of the rays as a depilatory in ordinary hypertrachosis is very properly condemned. The brilliant results often obtainable in eczema of the anus combined with pruritus should be borne in mind by every practitioner of medicine. The treatment of rodent ulcer by the X-ray tube is much lauded by some authorities. The author, however, testifies that the scar is almost certain to break down again sooner or later. This fact is not always estimated at the proper value in considering the therapeutics of the Röntgen ray in relation to lupus. In our own opinion, for the majority of cases early surgical measures are incomparably the best means of attack. This excellent little volume may be commended to all who need a condensed and trustworthy guide book to this branch of medical science.

THE ANALYSIS OF WATER. (*b*).

The scheme of analysis prescribed in this book is said to offer two advantages—the analysis is quickly done without involving the use of cumbersome apparatus and by persons having only a small knowledge of water.

Although there are parts of the world where expert analysts are non-existent, and where the collection of apparatus and chemicals supplied by Messrs. Burroughs Wellcome and Co. would be useful, it is probable that in very many cases where a proper chemical analysis could be performed, Dr. Thresh's less satisfactory scheme is followed, and Dr. Thresh would be the first to deplore this. Further, although a man may in a short time master the technique of water analysis, it requires years of continuous study before he can place a correct interpretation on the results of his analysis. Hence the scheme propounded in this book may, in the hands of a novice, be a source of great danger. Could the analysis of water be simplified, medical officers and analysts would be glad to accept the innovation, but as it is they are justified in declining to place lives in jeopardy by adopting the well meant but dangerous idea of Dr. Thresh.

(*a*) "The Röntgen Rays in General Practice." By R. Higham Cooper, L.S.A., in charge of the Radiographic Department at University College Hospital. London: Bailliere, Tindall and Cox. 1907. 2s. 6d. net.

(*b*) "Une Methode Simple pour l'Analyse de l'Eau." By John C. Thresh, M.D.(Vic.), D.Sc., D.P.H. Translated from the Fifth English Edition by Drs. Magnier and Thiry. Pp. 62. London J. and A. Churchill. 1907. To be obtained from Messrs. Burroughs Wellcome and Co., London.

Weekly Summary of Medical Literature, English and Foreign.

Specially compiled for The Medical Press and Circular.

RECENT GYNÆCOLOGICAL AND OBSTETRICAL LITERATURE.

Hyoscine Anæsthesia in Obstetrics.—Butler (*Amer. Journ. Obstet.*, August, 1907). Despite the discouraging reports of early observers, the new method of securing anæsthesia in obstetrics is being widely tested and rapidly coming into favour. The most important report on the subject is that of Gauss, of Freiberg, who gives his experience of 1,000 cases anæsthetised with hyoscine. He insists on the use of pure alkaloids, and he states scopalamine is apt to be contaminated with bodies which seriously modify its action. This seems not to be the case with hyoscine derived from hyoscyamus. The object sought is the production of a peculiar state of half narcosis, known as "twilight-sleep." From this the patient may be awakened at any moment if desired, but does not retain recollection afterwards. The first injection is given when the pains become really severe, and consists of three to four decimilligrammes of hyoscine with one centigramme of morphine. Half an hour later the patient is shown some test object, and in thirty minutes more is asked if she remembers what was shown her. On this Gauss lays stress, since the capacity to remember regulates the dosage, rather than the cries of the patient, which are less significant. When the patient remembers the test object, a second injection is given of hyoscine alone, unless the pain is excessive, and only then is the morphine repeated. Usually four injections suffice, at intervals of not less than one hour, generally two to four hours. The ears are stopped to exclude noises. The secrets of success lie in the choice of good, fresh preparations beginning with small doses, and careful testing of the memory power as a means of regulating the doses. The causes of failure are—forcing the effects by large doses too often repeated, beginning the process too early in the labour, or leaving it until there is not sufficient time for the effect to develop, or, finally, regulation of the dosage by the patients cries. In regard to the effects on the mother, Gauss found the women complain of thirst, as hyoscine lessens mucous secretions; hallucinations and delusions of transitory character were occasionally noted. No effect on the secretion of milk could be detected, and Gauss declares that hyoscine does the child *in utero* no injury whatever. F.

Care of Nipples and Breasts during Pregnancy and Lactation.—Lagusua (*Amer. Journ. Obstet.*, August, 1907. The author of this paper says that during pregnancy, if the nipples are well formed and not painful, no treatment except absolute cleanliness is necessary. If the nipples are small, it is best to use massage in the shape of traction for fifteen minutes daily during the last two months, using boracic acid vaseline as a lubricant. During lactation, the breasts and everything that touch them should be kept as aseptic as possible, and enveloped in sterilised gauze. If there are cracks in the nipples the application recommended is nitrate of silver, 1-10, applied with cotton on a stick. When the patient does not nurse her infant, the breasts and axillæ should be enveloped in cotton pads and a firm bandage applied, which remains on till the milk disappears from the breast. If they become painful and full, Rochelle salts should be given. When a patient is nursing, a bandage is used to support the breasts, and should they become painful, massage is used every four hours to distribute the milk evenly in the breasts. If there is not enough milk the patient should take milk, eggs, butter, and cream. If the breast becomes infected, massage is useful to remove the pus from the milk ducts; it should be given first lightly, then with more pressure, every four hours, with the use of the icebag between. When the skin becomes red and inflammation sets in the abscess must be opened and treated like an abscess in any other place. F.

A Contribution to the Ætiology of Chorio-epithelioma without a Primary Tumour in the Uterus.—Walthard (*Zeitschrift fur Geb und Gyn.*, Bd. LIX. Hft. 3) reports a case of chorio-epithelioma malignum occurring in the second half of a normal pregnancy of a woman, æt 27, who had previously been quite healthy. It was her fifth pregnancy, and from the middle of the seventh month she had suffered from hæmorrhage and a sanious discharge. The cause of this was found to be two polypoid growths about the size of hazel nuts with ulcerated surfaces which sprang from the anterior and posterior walls of the vagina. These were removed and examined microscopically. The diagnosis was chorio-epithelioma metastases. A Cæsarean section was consequently performed in the interest of the child, and was followed immediately by abdominal total extirpation of the uterus. The patient died seven months after the operation. The *post-mortem* examination revealed metastases, especially in both kidneys, in the lung and in the liver. Microscopical examination of the fresh uterus with the placenta *in situ* showed neither in the placenta nor in the uterus any appearance of a primary chorio-epithelioma of the placenta or of hydatidiform alteration in the villi. The microscopical examination, which was most thorough, had the same result. One may, therefore, conclude with certainty that even fatal chorio-epithelioma may extend to the different organs of a patient from the epithelium of the chorion or from the syncytium of the placenta without it being possible to find a primary tumour in the placenta either as a chorio-epithelioma, a hydatidiform or any other alteration of the placental cells. G.

The Recurrence of Carcinoma after Hysterectomy and the Treatment of Inoperable Uterine Cancer.—In a paper on this subject Hankel (*Zeitschrift fur Geb und Gyn*, Bd. LIX., Hft. 3) points out many unclear points which exist in the teaching regarding carcinoma uteri. He particularly wishes that one may be able to recognise from future reports on what grounds the different operators decide that operation is indicated, in other words, what cases are operable; and also in the different cases whether the carcinoma was primary in the portio or in the cervix. As regards recurrence the very rich material of the Berlin Klinik teaches the important fact, that, during hysterectomy for carcinoma, the glands need not be so very completely removed. If infiltrated glands are felt they are to be removed but unopened, because rupture of the gland capsule produces a greater danger to the patient than the retention of the carcinomatous glands in the abdomen. If the carcinoma is limited to the uterus, or is not extensively spread into the parametrium, the igni-extirpation of the uterus with, if it is necessary, Schuchardt's incision, is the best operation. The whole vagina or the greater part of it is to be removed at the same time. Every extensive infiltration of the pelvic connective tissue indicates laparotomy, as one can thus operate more radically. Every recurrence must be operated on if it is at all possible, and the earlier the better. In order to recognise recurrence at an early date the patients must report themselves regularly every ten to fourteen days. In cases of inoperable cancer the Paquelin and after that one of the usual caustics are to be employed. A single curetting and cauterisation of the carcinomatous tissue is not sufficient. The patients must remain under observation, and whenever necessary, the cauterisation is to be repeated. G.

Disappearance of Pregnancy: A Contribution to the Study of Hydatidiform Mole.—Polano (*Zeitschrift fur Geb. und Gyn.*, Bd. LIX. Hft. 3) records the following interesting case. The patient, æt. 28, had missed three periods. She had suffered from a bloody discharge for some days, and fever up to 39° C. To the left of the uterus, which was enlarged to the size of about four months' pregnancy, a soft tumour the size of half a fist was to be felt, so that a diagnosis of pregnancy of from three to four months, together with a left-sided pyosalpinx was made, at the same time the possibility of a tubal gestation was considered. The laparotomy revealed a distinctly pregnant uterus of from three to four months, the left ovary which contained many cysts enlarged to the size of half a fist, the right ovary smaller, but also cystic. Both tumours were removed, recovery was undisturbed, and there was no hæmorrhage from the uterus. When the patient was dismissed nineteen days after the operation the uterus was soft, but was certainly smaller than before the operation. The diminution in size continued without any appearance of hæmorrhage, so that nine months later a normal uterus 7 cm. in length by the Sound was to be palpated. As one cannot assume that a normal pregnancy at the third or fourth month thus completely disappeared, there only remains for this case the possibility that an abnormal product of conception had been present. This view is strengthened by the result of the microscopical examination of the ovaries which revealed the usual changes connected with hydatidiform mole formation. This case was therefore one of absorption of a hydatidiform mole which the author is inclined to believe was due to autolytic processes within the mole. G.

Hysterotomia Vaginalis Anterior.—Liepmann (*Med. Klinik*, 1906, Nr. 14) describes the technique of this operation, the vaginal Cæsarean section. Its chief indication is eclampsia. Since for this the author considers rapid and immediate delivery the best treatment, and as eclampsia usually sets in before or shortly after the onset of pains and usually that in primiparæ with rigid cervices, he considers that there is a wide field for this operation. In addition to this a series of placenta prævia patients were delivered by this method in Bumin's Klinik. It is also indicated in nephritis gravidarum, heart disease, lung disease, cicatricial stenosis of the cervix, carcinoma, premature detachment of the placenta, and even prolapse of the cord when the cervix is undilated. Dülussen's method of splitting the anterior and posterior walls of the cervix need not be performed, since it is possible to deliver large fully-developed infants by the one incision through the anterior walls of the vagina and uterus. The author's paper is the result of sixty-six cases, nineteen of which he had operated on himself. G.

MEDICAL NEWS IN BRIEF.

Tuberculosis in Ireland.

THE Women's National Health Association of Ireland, as already announced has organised a Tuberculosis Exhibition, on the lines of several held in America and on the Continent. The Exhibition will be open in the Home Industries Section at Ballsbridge during the last weeks of October, after which it is proposed to send it on tour to different parts of the country, beginning at Belfast, where a public meeting to inaugurate a branch of the Women's National Health Association is to be held about the beginning of November. The work of organisation has been in progress for some weeks, in the hands of a small Committee, under the presidency of Her Excellency the Countess of Aberdeen. A Consultative Committee is being formed, to which the leading medical societies and several public bodies have already appointed delegates. The meetings of the Committee are held at 76 Grafton Street, to which address any communications can be send to the Hon. Secretaries, Tuberculosis Exhibition.

THE QUESTION OF REPRESENTATION.

At the last meeting of the Public Health Committee of the Borough, a letter was read from the Women's National Health Association, asking the Public Health Committee to lay the matter before the Council, and to let them know if the latter would appoint two representatives on the Consultative Committee, to whom the scheme of the exhibition will be submitted for criticism and advice. The committee resolved: "That a copy of the foregoing communication be forwarded to the Local Government Board, with an intimation that the committee approve of the proposed exhibition, &c., and would be glad to appoint representatives to the Consultative Committee as requested; but, in view of their auditor's recent surcharges of the expenses of members attending meetings of associations not coming under the definition of 'conferences of local authorities,' they cannot see their way to authorise members to incur any expenditure in this instance, and they regret they must, therefore, abstain from being represented, unless the Local Government Board will authorise the outlay beforehand."

At yesterday's meeting the following reply from the Local Government Board was read:—"Local Government Board, Dublin, August 20th, 1907.—Sir,—I am directed by the Local Government Board or Ireland to acknowledge the receipt of your letter of the 15th inst., in connection with the attendance of delegates from the Corporation of Belfast, at the Tuberculosis Exhibition which is being promoted by the Women's Health Association; and I am to state that the Board are not in a position to give the Corporation the undertaking referred to in the conclusion of your letter. I am to point out that the auditor is bound under section 47 (2) of the Local Government Act of 1898 to surcharge payments made for any purpose not expressly authorised by statute.—I am, sir, your obedient servant, H. Courtenay, assistant secretary."

The Committee expressed their regret that under the circumstances they could not see their way to appoint representatives to act on the Consultative Committee of the proposed exhibition as requested, but intimated that if any of the members desired to attend at their own expense, the committee would facilitate them by giving them formal nominations to represent the Council.

Oyster Merchant Fined.

AT Colchester, on Saturday, William Bartlett, for 47 years an oyster merchant at Wivenhoe, was fined £20 and costs for selling Portuguese oysters which, according to the evidence of Dr. Klein, of St. Bartholomew's Hospital, were grossly polluted with sewage and contained an abundance of microbes. The prosecutors were the Wivenhoe Urban District Council, and Mr. Muskett, solicitor, watched the case for the Worshipful Company of Fishmongers. The Company's Chief Inspector stated that the defendant sold him the oysters from a bag, which was in such a position in defendant's yard that water from an adjacent sewer could flow over it. On receiving Dr. Klein's report, the district authority ordered the destruction of the defendant's remaining oysters and claimed a penalty against him for each unsound oyster, the total penalties claimed amounting to £160. The defendant had sent a sample of the oysters to D. Thresh, Medical Officer of Health for Essex, whose certificate stated that although not of a high standard of purity, the oysters were not grossly contaminated. The defendant stated that the oysters came from his pits at Tollesbury, and he and his family ate twenty-five for supper the night before the inspector called without harm resulting.

Mr. Morley and the Indian Government.

Following upon the King's letter comes an important blue-book despatch to the Governor-General written on July 26th. Mr. Morley says :—

"Your policy, in brief, is to rely for the present upon improved sanitation in towns, the co-operation of the people in the evacuation of villages, the destruction of rats, and such other measures as further investigations may suggest. You again consulted the Local Governments as to the expediency of constituting a special organisation for dealing with plague; but the reports of the Governments consulted are practically unanimous in condemning it as unsuited to Indian needs. Their reports are to the effect that suitable organisations for coping with the epidemic already exist, and that, although the executive may need strengthening in many cases, it is not desirable to strengthen it by importing medical men from England, who, being unfamiliar with the language and customs of the people, would not be qualified to direct measures which might involve interference with religious usage, and provoke a popular outbreak. The reports frankly recognise that the general sanitary service requires development, and that in this respect the needs of the times can be met by the employment of natives of the country. You state that proposals to this end are at present under your consideration. The fact that plague has been fatally active in India over eleven years, that the number of victims exceeds 5¼ millions, that its virulence is unabated and its progress uncontrolled, necessarily give rise to doubt as to whether everything that can be done has been done by the responsible authorities, and whether the last word of medical science and administrative skill has really been said. I wish with you that your efforts were attended with a greater measure of success. The conclusion expressed in the resolution of January, 1906, that 'in the last resort all preventive measures depend for their success upon the hearty co-operation of the people themselves,' while it defines the conditions of success, does not affect the obligation resting upon the governing powers of the country to endeavour to improve the quality of these measures, and win acceptance for them by skilled and considerate administration. I desire that no effort should be spared to arrest the spread of the disease by means acceptable to the people, and to give aid to the sufferers. I shall be glad to receive at an early date the proposals which are under your consideration for extending the general sanitary service by the increased employment of qualified natives of the country as medical officers of health and sanitary inspectors. Within reasonable limits of cost any proposals of the kind which you may submit will have my cordial support."

Medical Inspection of Schools.

Sir William Collins, on the 25th instant, asked the President of the Board of Education whether under the Education (Administrative Provisions) Bill there was any obligation on parents to submit children attending public elementary schools to medical inspection, as well as an obligation upon local education authorities to provide for such medical inspection.

Mr. M'Kenna: In the view of the Board the obligation placed by the Bill upon the authority to provide for inspection does not of itself compel a parent to submit his child to inspection.

Death of a Medical Man by Morphia Poisoning.

Mr. Walter Schroder conducted an inquest at St. Pancras, on August 24th, on Cyril Waldron Shaw, aged 42, bachelor, a doctor of medicine, found dead in bed at King's Cross, from the effects of morphia. The Rev. Seymour Shaw, Vicar of Warcop, stated that the deceased was his brother. He had been a good deal abroad in South Africa. He complained to witness of an abscess in the ear, which pained him acutely. Other evidence showed that Dr. Shaw complained to his landlord of a "maddening pain,' and wrote a prescription which he took to a neighbouring chemist, where he was supplied with twenty grains of morphia in a sealed packet Mr. Platt left him in bed on Wednesday night, and the next morning discovered him there lying dead. The bed-room door was unlocked. Dr. A. W. Dingley, Argyle Square; who had made an autopsy, said that no doubt Dr. Shaw had a severe pain in his ear, although there was no abscess. He suffered from bronchitis and alcoholism, and in his condition two or three grains of morphia would suffice to cause death. Death was due to morphia. A verdict of death by misadventure was returned.

St. Thomas's Hospital—House Appointments.

The following gentlemen have been selected as House Officers for the ensuing term. :—

Casualty Officers.—(Senior) W. O. Sankey, M.B., B.S.Lond., M.R.C.S., L.R.C.P.; (Junior), C. M. Page, M.B., B.S.Lond., M.R.C.S., L.R.C.P.

Resident House Physicians.—G. G. Butler, B.A. Cantab., M.R.C.S. L.R.C.P.; S. L. Walker, B.A., B.C.Cantab., M.R.C.S., L.R.C.P.; C. E. Whitehead, B.A.Cantab., M.R.C.S., L.R.C.P. (extension); H. G. Bennett, M.B., B.S.Lond., M.R.C.S., L.R.C.P. (*extension*); A. L. Loughborough, M.R.C.S., L.R.C.P.

House Physicians to Out-Patients.—W. H. P. Sutton, B.A., M.B., B.C.Cantab., M.R.C.S., L.R.C.P. (*extension*); S. Churchill, B.A.Cantab., M.R.C.S., L.R.C.P. (*extension*); B. T. Parsons-Smith, M.R.C.S., L.R.C.P.; A. J. S. Pinchin, M.B., B.S.Lond., M.R.C.S., L.R.C.P.

Resident House Surgeons.—H. J. Nightingale, M.B., B.S.Lond., M.R.C.S., L.R.C.P.; H. P. Unwin, M.A., M.B., B.C.Cantab., M.R.C.S., L.R.C.P.; G. M. Huggins, M.R.C.S., L.R.C.P.; F. M. Neild, M.B., B.S.Lond., M.R.C.S., L.R.C.P.;

House-Surgeons to Out-Patients.—H. H. Carleton, B.A., M.B., BCh. Oxon; R. E. Todd, M.B., B.S.Lond. M.R.C.S., L.R.C.P.; W. R. Bristow, M.R.C.S., L.R.C.P.; H. E. T. Dawes, B.A.Cantab., M.R.C.S. L.R.C.P.

Obstetric House Physicians.—(Senior) F. S. Hewett, B.A., M.B., B.C.Cantab., M.R.C.S., L.R.C.P.; (Junior) H. B. Whitehouse, M.B., B.S.Lond., M.R.C.S., L.R.C.P

Ophthalmic House Surgeons.—(Senior) A. S. Burgess, M.A.Cantab., M.R.C.S., L.R.C.P.; (Junior) A. I. Cooke, B.A., B.C.Cantab.

Throat.—R. G. Bingham, M.R.C.S., L.R.C.P.; A. W. C. Drake, B.A.Cantab., M.R.C.S., L.R.C.P.

Skin.—E. C. Sparrow, B.A.Cantab., M.R.C.S., L.R.C.P. (*extension*); J. F. Windsor, B.A. Cantab., M.R.C.S., L.R.C.P.

Ear.—W. H. G. Verdon, M.R.C.S., L.R.C.P.; W. Patey, M.R.C.S., L.R.C.P.

Children's Surgical.—W. A. Morton Jack, M.R.C.S. L.R.C.P.

Society of Apothecaries of London.

The following candidates passed the necessary examinations, and have been granted the L.S.A. Diploma of the Society, entitling them to practise medicine, surgery, and midwifery :—C. L. Driscoll and E. E. Wilbe.

A sixth edition of "The Pharmacopœia for Diseases of the Skin," by Dr. James Startin, has just been published by Messrs. John Wright and Co., of Bristol. This little work contains in condensed form much useful information about diseases of the skin, and many valuable formulas for their treatment. The author has also drawn up a few rules of diet and some general directions on the management of skin lesions, and the work is completed by a dermatological classification and a therapeutic index. Practitioners who have not yet met with the book in its previous editions will find the present one a pleasing addition to their therapeutic resources.

NOTICES TO CORRESPONDENTS, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

D. R. H. — We are in accordance with the general opinion of the public on the subject, namely, that chicory is not injurious. If it had been, the fact must have been widely known long ere this. Occasional bad results have been reported, but these may be due to idiosyncrasy, or, what is more likely, to some other root having been accidentally substituted for chicory. The chemistry of chicory has not been much studied, we believe, but it is obvious that there can be no directly injurious substance present. It has little or no dietetic value.

R. P.—Your question is rather an odd one, but we are sufficiently versed in comparative anatomy to be able to assure you that dogs do suffer from sea sickness. Nor are they the only animals which do, for horses and cattle are subject to the malady too. The question was treated of in the spring by M. Landrieux, who read a paper before the Societé de Pathologie Comparée in Paris, in which he gave some striking instances. One fox-terrier puppy, eleven months old, fell an easy prey to the malady. The symptoms were practically the same as in man. Lack of interest in surroundings, dejection, salivation, and vomiting with rapid recovery on reaching *terra firma*.

L. K. Q. C. P. I.—The prizes (£25, £10, and £5) offered by Mr. George Sturge for authors of the best essays on "The Causes of Financial Depression in the Hospitals of London, with Suggestions for Improving their Administration in Finances," were proposed in August, 1886.

Podagra-Marlioz is a suburb of Aix-les-Bains, and connected therewith by a good omnibus service. It is only fifteen minutes' very pleasant shaded walk from centre of Aix. The three Marlioz springs are cold, alkaline, sulphurous, and bromo-iodinated. Their waters are *specially* efficacious for bronchitis (chronic, catarrhal, asthmatic), chronic diseases of the larynx. pharnynx, nose, ears, and uterus. The Marlioz Bath Establishment contains large inhalation-rooms, fine spray apparatus, and local douches for nose, throat, etc. Dr. Mace (of Aix-les-Bains) has published excellent articles and pamphlets on Marlioz waters and treatment. For further particulars write to the Director, Marlioz Baths, Aix-les-Bains.

A SUCCESSFUL FAT CURE.

We are not prepared to confirm or deny the last of the following statements from our contemporary, the *Pelican*, but if it be true we certainly agree that it is not "unfunny":—"That the various medicines for reducing the ultra-plump and making them sylph-like still continue to be very freely advertised and commented upon in singularly favourable fashion by the papers in whose columns the advertisements appear. That many of these preparations are dangerous things to take. That anyhow it is not an unfunny thing to reflect on the fact that the chief proprietor of a certain greatly advertised fat-reducer weighs over *twenty-two stone himself*—or did so last week!"

D. R. A.—The tumour may be malignant, but such growths generally occur in old-standing goitres. Carcinoma and sarcoma both occur; it is practically impossible to distinguish the two by merely clinical examination. Removal by operation can be undertaken, but the prognosis is not very rosy.

Tonus.—The question of pressing for payment must, we think, be left to your own judgment. If taken to court, we have no doubt twenty guineas would not be considered out of the way. That the patient expected that you would do the operation gratuitously would be no defence in law, unless there was a very clear understanding to that effect, as it is obvious that a man does not expect a surgeon in the ordinary way to do operations for charity. If you showed that he had reasonable means, we think you would be quite safe to recover.

Meus.—We do not know anything of the institution in question, and cannot therefore advise. It professes to be run on ethical lines, and may be genuine. There is a "fishy" look about it, we agree, and while there are other excellent institutions of the kind elsewhere, you would be well advised to go where you can repose confidence.

Pater.—Of course, the adding of a fifth year to the medical curriculum has made a difference in the fees charged by London hospital schools. Moreover, the larger number of practical classes has necessarily made study more expensive. In the old days the composition fee was roughly a hundred guineas, if paid in one sum, and about £120 if paid by instalments. As we said last week, the average composition fee is now about £130 or £140.

Vacancies.

Mickleover (Derby) County Asylum.—Junior Assistant Medical Officer. Salry £120 per annum, with furnished apartments, board, washing, and attendance. Applications to Dr. Legge.

West Herts Infiramry, Hemel Hempstead, Herts.—House Surgeon. Salary £100 per annum; rooms, board, and washing found. Applications to the Rav. W. T. T. Drake, Boro' Gate, St. Albans.

Bedford County Hospital.—House Surgeon. Salary £100 per annum, with apartments, board, and laundry. Applications to W. F. Morley, Secretary.

Edmonton Union.—Assistant Medical Officer. Salary £180 per annum, and £40 per annum in lieu of residential allowance. Applications to F. Shelton, Clerk, White Hart Lane, Tottenham.

Toxteth Park Township.—Assistant Resident Medical Officer. Salary £100 per annum, with board, washing, and apartments. Applications to R. Albert James, Clerk to the Guardians, 15 High Park Street, Liverpool.

Bridgnorth and South Shropshire Infirmary.—House Surgeon. Salary £100 per annum, with board and lodgings in the Infirmary. Applications to the Hon. Secretary, the Infirmary, Bridgnorth.

Egyptian Government.—Kasr El Ainy Hospital.—Resident Medical Officer. Salary £250 a year, with quarters, servants, washing, coal, and light. Applications to the Director-General, Public Health Department, Cairo.

Egyptian Government.—Ministry of Education.—School of Medicine, Cairo.—Assistant to the Professor of Pathology. Salary £E.320 per annum. Applications to the Director, Government School of Medicine, Cairo, Egypt.

Loughborough and District General Hospital and Dispensary.—Resident House Surgeon. Salary £100 a year, with furnished rooms, attendance, board, and washing. Applications to Thos. J. Webb, Secretary, Loughborough.

Scarborough Hospital and Dispensary.—Senior House Surgeon. Salary £100 per annum, with residence, board, and allowance for laundress. Applications to the Hon. Secretary.

Wallasey Urban District Council.—Medical Officer of Health. Salary £500 per annum. Applications to H. W. Cook, Public Offices, Egremont, Cheshire.

Barnsley.—House Surgeon. Salary £100 per annum, with board and lodging. Applications to R. F. Pawsey, Honorary Secretary, Barnsley.

Leicester Corporation.—Isolation Hospital.—Resident Medical Officer. Salary £120 per annum, with board, lodging, and washing. Applications to C. Killick Mallard, M.D., Town Hall, Leicester.

Leicester Parish.—Resident Assistant Medical Officer. Salary £120 per annum, with rations, furnished apartments, and washing. Applications to Herbert Mansfield, Clerk to the Guardians, Poor-Law Offices, Leicester.

London County Asylum, Long Grove, Epsom, Surrey.—Fourth Assistant Medical Officer. Salary £180 a year, with board, furnished apartments, and washing. Applications to H. F. Keene, Clerk to the Asylums Committee, Asylums Committee Office, 6 Waterloo Place, S.W.

Appointments.

Ball, W. Girling, F.R.C.S.Eng., Assistant Surgeon to the City of London Truss Society.

Gask, G. E., F.R.C.S.Eng., Surgeon to the City of London Truss Society.

Gorham, P. C., L.R.C.P. and S.Edin., Certifying Surgeon under the Factory and Workshop Act for the Clifden District of the County of Galway.

Harvey, Frank, M.R.C.S., L.S.A., Public Vaccinator for the St. Issey and St. Breock Districts by the St. Columb (Cornwall) Board of Guardians.

Hustler, G. H., M.B., Ch.B.Leeds, Government Medical Officer for Fiji.

Niven, A. M., M.B., Ch.B., on the Resident Medical Staff of the Royal Infirmary, Aberdeen.

Stewart, Alex., M.B., Ch.B., on the Resident Medical Staff of the Royal Infirmary, Aberdeen.

Walford, Harold R. S., M.R.C.S., L.R.C.P.Lond., Assistant House Surgeon at the Coventry and Warwickshire Hospital, Coventry.

Marriage.

Dowden—Oswald.—On August 21st, at St. Mary's Cathedral, Edinburgh, John Wheeler Dowden, F.R.C.S.E., to Edith Georgiana, younger daughter of the late Surgeon-General H. R. Oswald, I.M.S.

Deaths.

Antrobus.—On August 22nd, at The Chase, Great Malvern, Edmund Antrobus, M.D., aged 45.

Margrave.—On August 10th, at Moffat, N.B., Malcolm Llewelyn Margrave, M.R.C.S., L.R.C.P.Lond., late of Llanelly and Newton Abbott, aged 42 years.

Maurice.—On August 20th, at the Vicarage, Isleworth, Benjamin Maurice, M.R.C.S., L.S.A., of 12 Osborne Road, Clifton, Bristol, son of the late William Maurice, of Clifton, formerly Surgeon to the 7th Hussars.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXV. WEDNESDAY, SEPT. 4, 1907. No. 10

NOTES AND COMMENTS.

Small Holdings. AFTER a full and eventful session, Parliament rose last week, leaving behind it an amount of completed legislation of considerable and varied importance. The session is notable among many other things for the number of measures dealing, directly or indirectly, with public health and medical polity. Foremost among these stands the Small Holdings and Allotments Bill, which in principle was uncontroversial, though in practice its details came in for a good deal of criticism. If the anticipations of the promoters and supporters of this measure are realised, it may have exceedingly far-reaching results on the physique of the nation, for it will bring into existence a large class of peasant tillers of the soil, than whom no hardier and more virile men can be found. The nation which consists principally of town-dwellers is obviously a nation living under conditions not conducive to the best physical development, and the population of large towns such as are growing with apparently irresistible force in England, is bound sooner or later to lose the sturdy qualities that the wrestle with the land under sun and hail bring out and keep alive. We are hardly sufficiently optimistic to expect that this new Act, or even a series of similar ones will greatly change the current economic factors, but it is just possible that it may establish in this country a class of public tenants who will be available as a source of recruiting for townsfolk, and that thus a good backbone of physical resource will be created. At any rate, the Act is beneficent and praiseworthy in intent and it is only a pity that a technical detail of administrative arrangement should have prevented Scotland enjoying similar opportunities.

Education (Administrative Provisions). THE next most important achievement of the session has been the passing into law of the Education (Administrative Provisions) Bill, and it has shown Mr. McKenna to be possessed of a quality rare in politicians, namely, that of fulfilling in fact more than he would promise in prospect. This bill again was practically non-controversial, especially as the details had been pretty well thrashed out last year in Mr. Birrell's ill-starred and more comprehensive measure. By this Act the Board of Education are authorised to organise the work of medical inspection of elementary school children throughout the country, and the birth of school hygiene may now be looked upon as an imminent event. If we may be allowed to offer advice on this subject we would of all things implore the President of the Board of Education to beware of the faddists in making his arrangements for this duty. There is a large class of unmarried ladies of unimpeachable motives and of elderly bachelors read in the schools of Tübingen who, by reason of their interest in the subject of the education of children, are looked upon as "experts." May Mr. McKenna eschew such "experts"! The science of school hygiene is yet in its infancy and has little of technical lore of its own. It is yet, and is likely for many a day to be, but the sanctified commonsense of a wise physician who is acquainted with hygiene and acquainted with children. The headquarters medical staff will be effective or ineffective in creating an effective administration of the provisions of the new Act in so far as they are not committed to any scheme of Scandinavian gymnastics, exotic anthropometry, or other doctrinaire panaceas. The British child is a person who likes play, dislikes book-work, and is subject to certain ailments. His salvation may be worked out largely by attention to his limitations.

Public Health Acts. ANOTHER beneficent measure is the Public Health (Regulation of Food) Act, which has safely found its way to the Statute Book. As we have often pointed out in these columns the outburst of indignation against Chicago was largely an outburst of ignorance, the people of this favoured land fondly imagining that all their food was of the best in the best of all possible countries. On the contrary, the amount of bad and diseased food openly and covertly trafficked in is enormous, and the safeguards provided by law, the seizure of unsound food intended for the food of man by the health officials, and its destruction by magistrate's order, largely illusory. The respect of the Constitution for the sacred rights of property is no less exhibited in practice than in legislation, and not only is it difficult to prove the food is intended for the food of man, but magistrates are often extremely lenient to owners of such food. Now, however, the local authorities have far larger powers of inspection and control over food supplies and places where food is kept, and it may confidently be anticipated that, if properly used, there will be far less ill-health and death from the consumption of offal of various kinds which has been refused by the stricter regulations of foreign countries and dumped on these shores. Mr. Burns also got through another Public Health Bill, and his Vaccination Bill for tempering the wind of magisterial criticism to the shorn conscientious objector, and the Secretary for Scotland, besides performing the latter service also for his country, obtained a small but needful change in its own Public Health Act.

Notification of Births— OF the Notification of Births Act it is difficult to write temperately. In object it is praiseworthy enough, for it aims merely at giving the medical officer of health early information of births in his district, so that he may be in a position to take steps to see that the children are properly cared for by their mothers in the first few days of their lives. Whether the steps taken will conduce to that desirable end naturally remains to be seen, but the point which affects medical men, and which we dealt with at length in our leading columns last week, is that it places a new and definite obligation on private medical men pursuing their profession, without fee and yet *with* penalty in default of the father notifying. The time really seems to be ripe for some definite movement among members of the profession for letting the public know that while they are willing and anxious to promote the public weal in every reasonable way, they do object to be constituted informal spies on their patients, and they do object to be laden with responsibilities which may land them in the police-court, and for which they receive no compensation. The habit of regarding the medical man as a beast to bear the communal burden is growing alarmingly. The Midwives' Act made him responsible, of course without payment, to hold himself in readiness to obey the summons of every midwife who found herself in difficulties, without giving him any control over the midwife's practice. The indignity thrust on him by this new Act is scarcely less, and to prate in high-falutin' style about doctors' benevolence is only to take an unconscionably mean advantage of the present private charitableness of medical men. Were the appeal made to medical benevolence and to that alone, a response, we believe, would be forthcoming, but a police-court penalty is an abominable outrage.

And other New Acts. As to other Acts, we, as members of a working profession, have to thank the Chancellor of the Exchequer for the relief granted in the income-tax. It has always been a patent anomaly that the worker should be taxed at the same rate as the drone, and though, as in all enactments, there will be certain hard cases, the broad principle of preference for the earner as against the beneficed is now established. Medical men will wish all possible success to Mr. Asquith's cleek and gun during the next few months. They will perhaps not care much one way or the other as to the measure which enables women to sit on local bodies. Theoretically the gentle influence of the sex should have play in the sphere of minor government, but it is a rather common experience to those who have served on and under such boards that though many excellent ladies have done good work on them in the past, there is an unfortunate tendency for the Martha rather than the Mary variety to seek municipal honours. With the growing interest in local government, let it be hoped the electors will learn to discriminate between their respective qualifications.

Great Wyrley Outrages. THE fresh series of cattle outrages at Great Wyrley lends confirmatory evidence, if any were needed, to the innocence of George Edalji of the crime with which he was originally charged, and we believe there are few people now who believe him guilty, even in the neighbourhood where prejudice against him is very strong. Whether the police or Sir A. Conan Doyle, or both, succeed in nailing the real malefactor, the fact remains that an innocent man has already suffered for a crime which it was obvious all along to scientific minds he had not committed. The question has been discussed over and over again in these columns, but the share taken by the MEDICAL PRESS AND CIRCULAR in protesting against the Edalji conviction, and petitioning for his release has been eclipsed and forgotten in the sensational events of the last few months.

LEADING ARTICLES.

AN EXPERIMENT IN SCHOOL MEDICAL INSPECTION.

THE question of the medical inspection of schools has of recent years come definitely within the range of practical politics. On all hands its importance has been recognised not only as a means of checking the spread of communicable diseases, but also of controlling the physique of rising generations and of supervising the conditions of school environment. An important experiment in this direction has been made by Dr. Myer Coplans, Medical Inspector of Schools, Gloucestershire Education Committee, who communicated a valuable paper on the subject to the recent International Congress of School Hygiene. The local County Education Committee in question desired to improve the condition of certain elementary schools in which the attendances, and, consequently the grant-earning capacity, had been seriously impaired by reason of the continued prevalence of contagious skin affections among the scholars. Under then-existing legislation, however, there were no statutory powers enabling an official medical examination of the children to be made without the consent of parents. It therefore became necessary to devise some means of ascertaining the facts of the case as regarded the skin diseases mentioned, at the same time respecting the rights of the parents. This difficulty was overcome by Dr. Coplans circularising the parents of some 8,000 children, with the result that 97 per cent. of them agreed to his proposals. His plan was to issue a card, which was intended to accompany the child through his or her school life. On one side of the card were particulars filled in by the parents concerning the child's ailments, the medical history, and questions as to tuberculosis in the family. On the other side were notes made by Dr. Coplans at regular intervals concerning the child's physical and mental development, condition of skin, state of vaccination, together with remarks when necessary on the special senses. For each of the sixty schools under observation there was instituted a medical register in which was tabulated standard by standard the condition of individual scholars as shown by the card. He found the columns relating to the records of zymotic disease of great assistance in determining the probability of spread of any particular form of disease in any standard, department, school, or even village, and he recalled one case of a village concerning which the columns relating to measles showed at a glance that there had been no instances of that disease for more than seven years. He was therefore prepared to advise school closure on the appearance of the first case of measles in that particular village. The advantages of the scheme thus outlined are conspicuous. One of the chief recommendations is the continuity of record which is secured in the case of each individual child. Further, an accumulation of statistical data would be secured that could hardly fail to be of the greatest value in the future study of the complex conditions of school life. Early and continuous information, moreover, would be furnished of affections of the special senses, and of those abnormalities of mind and body which render a separate classification imperative in any well-organised educational system. So far as private schools are concerned, it may be anticipated with a fair amount of confidence that it is only a matter of time for them to fall into line with the movement that is now being established in State schools. Probably one of the chief obstacles in the way of general medical inspection will result from financial considerations. In dealing with infectious diseases, notification alone is useless without the corollaries of isolation and disinfection. So in educational life medical inspection without accompanying powers and available classifying and remedial agencies, would be of little value. It is one thing to inspect the eyesight of a million of school children, but another matter altogether to provide spectacles for those who need them. A similar observation, *mutatis mutandis*, applies to other physical and mental defects. As a sound contribution to the attack on a complicated problem, Dr. Coplans' Gloucestershire experiment is worthy of the attention of the medical profession.

CURRENT TOPICS.

Value of Science in Montgomery.

There are few counties which have yet recognised the value of the powers their Councils are endowed with for appointing medical officers of health. There are, however some which have availed themselves of the privilege, and though the salaries paid are seldom such as to entice men from other posts, in some counties the medical officer of health is paid a moderate living wage. Of late a new plan has been adopted by a number of these authorities which desire to be considered at once enlightened and economical, namely, to appoint as medical officer a man engaged in other work and to pay him a small salary and certain fees for such work as the Council commission him to do. The salary is usually exceedingly small and the fees nominal, but the county escapes the reproach of not having a medical officer of health. As the result of the pressure of public opinion, the Montgomery County Council have decided that they, too, shall have a medical officer of their own; so they have advertised for one and laid down an elaborate scheme of duties for the successful candidate. The salary was not specifically stated, but it turns out that these responsible and arduous duties are to be performed for the ambassadorial salary of five-and-twenty guineas a year! How such a post is to attract anyone who proposes to do his work thoroughly no reasonable person can conceive, and it is absurd to suppose that anything but the most nominal compliance with any of the specified rules is required. In a word, the policy of the Montgomery County Council appears to be one of throwing dust in the eyes of the public by swaggering off a medical officer of health, when for all practical purposes such an officer does not exist. County medical officerships should be among the prizes of the profession, and should be paid so as to attract the very best men; in hardly any county is their salary more than moderate, but in Montgomery it is farcical.

Inebriates' Homes.

The report for last year of the Inspector under the Inebriates' Act has just been issued, and it is as careful and suggestive as usual. It is noticeable that whereas the number of men committed to institutions under the Act has increased from 91 to 110, the number of women has fallen from 352 to 294. There have been many signs lately that magistrates are losing faith in inebriate retreats for women, and it is not altogether surprising that this should be so, for the number of "cures" is exceedingly few. The reason for this is that prisoners can only be committed after four convictions within a year, and this safeguard to individual liberty successfully assures that none but the most confirmed inebriates are arrested. Now, with all respect to individual liberty, it is beyond reason to expect cures or any efficient reclamation among women of this class, and it is not wonderful that magistrates are getting to lose faith in retreats and to send fewer women to them. It is a striking fact, as shown in the inspector's report, that three-quarters of the crimes perpetrated under the influence of drink for which women are committed, consist in neglect of children. The numbers actually are 291, out of 364 total crimes. Of the other crimes, those of violence are remarkably small, there being only one conviction for manslaughter, two for malicious wounding, and seven for assault. At the present day, when so many beneficent measures are taken to promote temperance, it is a pity that the law does not give greater opportunities to officials to enter the homes of drunken mothers and protect the children.

Alcohol and Mountaineering.

No better example of the altered attitude of the public mind toward the use of alcohol can be adduced than the fact that it is rapidly passing out of use by mountaineers. It is but a few years since brandy was regarded as a requisite in every climbing expedition, and it was a rash climber who ventured out without it. Nowadays, it is not used at all as a beverage while climbing, and it is only carried for use in case of accident or to sustain life in case of prolonged exposure. Dr. Schneider, an Austrian physician, has recently administered interrogatories to some 1,200 climbers with a view to discovering their experience and opinions based on their personal use of alcohol. They are practically agreed in believing that alcohol should be reserved for special occasions, and is to be regarded as a hindrance rather than as a help in the ordinary course of climbing. This is, indeed, what might be expected, when it is remembered that there are few occupations which demand a truer eye, a steadier nerve, and a cooler head than does mountain-climbing. The beverages which have taken the place formerly occupied by alcohol are cold tea and cold coffee, which are stimulating and refreshing without possessing the incoordinating effects of alcohol. We have no doubt that another few years will see the disappearance of the brandy-flask from the hunting-field as it has already gone from the glacier and the rock.

Deaths Under Anæsthetics.

THE proportion of deaths under general anæsthetics, as already insisted upon in these columns, varies in different hospitals to such an extent as to suggest the desirability of careful scientific investigation. That there will always be an irreducible minimum of fatalities under such circumstances appears to be more than likely. There are certain obvious points that are capable of reduction to systematic and detailed statement, such as, for instance, the experience of the administrator, the nature of the anæsthetic, and the kind of apparatus used in each given case. In some quarters it is customary to assume that ether is absolutely safe, and writers upon chloroform deaths are wont to ignore deaths from the former drug. Attention may be drawn to a case reported in the news columns of our present issue, in which death resulted after four ounces of ether had been administered. Dr. Waldo, the City of London Coroner, has taken up the question of deaths under anæsthetics with his usual vigour and thoroughness, and we may hope for extended and authoritative investigation on a point of the utmost practical importance, not only to medical science but also to the welfare of the public.

Opening of the New Wing at the Rotunda Hospital, Dublin.

THE new wing, which has been lately added to the Rotunda Hospital, was formally opened on Tuesday of last week by Her Excellency Lady Aberdeen. The new wing adds to the older buildings six additional wards, by setting free the entire top-floor of the Plunkett Cairnes Wing, which up to this had been used as a nurses' home. It also provides a new lodge, and residential quarters for lady students, a disinfecting chamber for bedding and patient's clothes, and an ample supply of bath-rooms and lavatories. The Master of the Hospital, Dr. Hastings Tweedy, in the course of the statement with which the proceedings on Tuesday commenced, referred to the urgent need which existed for providing additional accommodation on the midwifery side of the house. The number of applicants for admission has increased enormously, with the result that the existing wards are overcrowded. The Rotunda Hospital has always boasted that no patient has ever been turned away, but had it not been for the new wards such a course would inevitably have had to be adopted. The new wing, which connects the central portion of the hospital with the lodge, cost over £8,000, and by its completion the claim of the Rotunda Hospital to be in the first rank in the United Kingdom, both in its accommodation for patients and for students, is made more patent than ever. The Master of the Hospital deserves the very greatest credit for the energy which he has shown in bringing about this new addition to his hospital.

Tuberculosis and Work on Farms.

THE problem of the eradication of tuberculosis, like many other social matters, is more or less closely associated with the land question. Other things being equal, it can hardly be doubted that country air is far less conducive to tubercular affections than that of towns. So far as actual treatment is concerned, open-air sanatoria are available for only a small proportion of consumptives. Under present conditions the cost of maintaining such patients indefinitely is simply prohibitive to local authorities. Any proposal, therefore, which suggests any way out of the difficulty deserves the earnest consideration of sanitarians. From this point of view Dr. Robertson, the Medical Officer of Health at Leith, makes a practical suggestion that is worth attention. Dealing with the difficulty of effecting cures in the majority of cases of tuberculosis, he expresses an opinion that what we really want is farm accommodation where patients, after a specified period of residence in hospital, may be sent to work in the open-air for several months. This proposal is excellent from various points of view. It would, for instance, not only be the best of all occupations for the patient, but it would isolate the infection in a place where it would be harmless, and would supply the farmer with labour at moderate wages. It is not unlikely that the system of farm colonies has a future in various maladies other than tuberculosis. Under good management the plan might be made to a great extent self-supporting.

Medical Man Shot Dead by a Lunatic.

THE special perils of medical professional life have been once again demonstrated by the tragic murder of a medical man in Leeds. With much regret and sympathy we have to record the fact that on Saturday last Dr. Walter C. Hirst, of Chapeltown, Leeds, was shot dead on his own doorstep by a man named Harrison, who immediately afterwards shot himself. It appears that the assailant had been attended by Dr. Hirst for a week or so for some affection of the brain, and was about to be certified for admission to a lunatic asylum. A letter sent by Harrison to a friend shows that he was the victim of delusions. It refers twice to the fact that the doctor struck him on the knees and knee-caps, and asserts that the proceeding in question brought on "terrible epileptic fits." The man went to the house at six o'clock in the morning, when Dr. Hirst, thinking the servants would not be up, went down to the door himself, and instantly received two shots from a revolver through the front of the chest. There were no eye witnesses of the event, but both bodies were found a few minutes later lying about five yards apart. Dr. Hirst was 28 years of age, and had been married only three months. The delusion as to the blows on the knees appears to have arisen from the ordinary testing of the activity of the knee-jerks. Fuller details of the tragic occurrence will be found in our news columns.

Notification of Epidemic Cerebro-spinal Meningitis in London.

Some time since we ventured to predict that the invasion of London by epidemic cerebro-spinal meningitis was simply a matter of time. The gradual spread of the malady in Ireland, Scotland, and certain provinces in England suggested that inevitable conclusion. The recent occurrence of several cases in the metropolis tallies with the usual history of invasion in in which these herald cases are the invariable precursors of an extended outbreak. The gravity of the position appears to be recognised by the London County Council extending the notification of this special form of meningitis for eighteen months further from September 13th, 1907, the date of expiry of the present order. It is expressly intimated that the term "cerebro-spinal fever" does not include meningitis due to tuberculosis, syphilis, middle-ear disease or injury.

The Tuberculosis Exhibition in Dublin.

The main features of the scheme for the Tuberculosis Exhibition, which is being organised by Her Excellency the Countess of Aberdeen, were put before a meeting of the Consultative Committee last week, and met with cordial approval. The Consultative Committee consists of representatives of the various public health authorities, of the various medical corporations and societies, and of other bodies likely to be interested in the matter, and Lady Aberdeen has acted with her usual wisdom in thus enlisting the sympathy and interest of many representative men. The present plan is that the exhibition, which is to open in October, shall consist of seven sections: "Diagrams and Statistics," "Pathological and Bacteriological," "Dietary," "Literature," "Appliances bearing on Treatment," "Veterinary," and "Lectures and Demonstrations." Each section is in the hands of an organiser, and the list of organisers shows a very careful and proper selection. Among them are the Registrar-General, Dr. Alford Boyd, Dr. Lily Baker and Professor Witham, of the Royal Veterinary College. The organisers gave to the Consultative Committee brief sketches of their plans, which were sufficient to show that the exhibition cannot fail to have educative effects of great importance in many directions.

PERSONAL.

Major V. H. W. Davoren, from Devonport, has taken over the duties of Medical Officer at Bury St. Edmunds, *vice* Lieut.-Col. R. Anderson, F.R.C.S.Edin., retired under the age clause.

Dr. M. Cameron Blair has been promoted to be senior medical officer in Southern Nigeria. Mr. W. H. Langley, C.M.G., has been appointed principal medical officer of the Gold Coast.

Dr. E. I. Spriggs has been elected Dean of St. George's Hospital Medical School.

At St. George's Hospital the Medical School Committee have decided to place a brass tablet in the new pathological laboratory in memory of the late Dr. Robert Barnes.

The death of Dr Seneca Powell, of the New York Post-Graduate School of Medicine, is attributed to his investigations into carbolic acid poisoning He had frequently experimented on himself, and this is believed to have undermined his constitution.

Dr. Henri de Rothschild, who goes out to Tangier in charge of the hospital he is to establish there, is the elder of two sons of the late Baron James Edward de Rothschild, of London, who, in his turn, was the elder of the two sons of Nathaniel, the third son of Nathan Mayer, the founder of the English house. The Rothschild hospital in Paris, which he superintends and works by himself, is open to all, irrespective of religious creed. About nine months ago he added to his other benevolences the gift of 100,000 francs to start a Cancer Research Institute.

Sir T. Lauder Brunton will deliver the inaugural address of the winter session of the London School of Tropical Medicine, on Monday, October 21st, when the chair will be taken by Mr. R. L. Antrobus, Assistant Under-Secretary of State for the Colonies.

Earl Grey, Governor-General of Canada, recently opened a consumptive sanatorium in Toronto, to be known as the King Edward Sanatorium.

Director-General Sir Alfred Keogh, K.C.B., has been appointed Honorary Physician to H. M. the King.

Much to the regret of the Executive Committee of Winsley Sanatorium, Dr. Lionel Weatherly has resigned the chairmanship on the grounds of ill-health and his removal to Bournemouth.

Dr. Moure, the famous Bordeaux surgeon, will in a few days be summoned to the Miramar Palace, where he will operate on King Alphonso for adenoids.

We beg to offer our warm congratulations to Sir Henry Alfred Pitman, who has just entered upon his one-hundredth year, and is the oldest physician in the United Kingdom. Sir Henry took his M.D. at Cambridge in 1841. From 1858 to 1889 he was Registrar of the Royal College of Physicians, and is still the Emeritus Registrar. Sir Henry, who enjoys good health, and is very active considering his great age, resides at Enfield.

A Clinical Lecture
ON
ABORTIVE FORMS OF TABES.

By PROFESSOR F. RAYMOND, M.D.,

Of the Faculty of Medicine, Paris; Physician to the Salpétrière Hospital, Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

Physicians who have opportunities of studying cases of locomotor ataxy and of observing them over long periods of time are forced to the conclusion that the classical description with which text-books have familiarised us does not cover the whole ground. Each patient makes a selection, so to speak, from the symptomatology and presents a special group of symptoms which thereupon assumes an individual aspect so that no two tabetics are exactly alike.

This polymorphism is particularly misleading in the præataxic period. It is indispensable that we should be acquainted with the various forms in which the disease may present itself at the onset, and I propose to discuss three cases in which the diagnosis offered some difficulty.

Our first patient is a woman, æt. 37, a dressmaker, whose past history is pathologically uninteresting, except that she admits alcoholic excesses. One afternoon last winter she was returning home on foot when she noticed a sudden numbness which started in the left foot, gradually extending to the whole limb, then spread to the hand and arm, in short, all the left side of the body except the face was similarly affected. The side seemed "dead" and felt very cold. She felt giddy and had to lean against the wall to avoid falling down. It passed off in about ten minutes and she went home.

Three days later the same thing occurred, but this time on the right side, when the face and tongue were affected. For a few minutes she was unable to speak and had to lean against a wall, but again in a few minutes the sensation passed away. Four days later, still in the afternoon, she had a similar attack at home, the face not being involved.

She has had no further recurrence of the symptoms, but at every sudden movement she feels jerks and trembling in the left foot, and more recently a tremor of the left side of the face. These are the symptoms that brought her to the Salpêtrière. Her general health is good, she does not suffer from headache or disturbances of the special senses and motility is perfect.

Now this patient presents none of the stigmata of the neurotic subject, nor a trace of hysteria, and if I raise this question it is only in order to impress upon you that you must never omit to ask yourselves the question, in presence of nervous manifestations, whether these are not purely functional.

The organic origin of these symptoms having been established there is only one term to describe a sensory crisis which starts at the distal end of a limb, spreads all over the body and ends in a brief lapse of consciousness, *viz.*: Jacksonian epilepsy. This term may suggest to you the idea of a convulsive motor manifestation, but such attacks are often preceded or accompanied by sensory phenomena, pain, numbness, tenderness, etc. This localised epilepsy may indeed assume a purely sensory form of which I have seen numerous instances, mostly followed by an "absence of mind" or vertigo, rather than by comatose loss of consciousness with stertor. This case belongs to the latter category.

The pathogenesis of the syndroma has not as yet been cleared up, but we know at any rate that the cause must be looked for in irritation of the grey cortex in the sensory motor zone. In this patient, however, we do not at first sight find the ætiological factor which would explain this irritation. She has had no recent or previous injury to the cranium since there is no headache, no vomiting, no vertigo, no ocular phenomena. It is not an exogenous intoxication, there is neither diabetes nor renal inadequacy. In fact we have no objective sign to guide us so we must trust to close examination of the patient to reveal some symptom which will put us on the track of the underlying cause, for though it is not mechanical or toxic it may be reflex or vaso-motor.

The woman tells us that she has no trouble in walking, and, as a matter of fact, on superficial examination, her steps are regular and she even walks straight. But if we make her turn round suddenly or tell her to go down stairs without looking at her feet she is embarrassed and hesitates. In the erect position too, things look normal, yet when she is told to stand on one foot she sways, showing a disturbance of equilibrium. There is then some slight incoordination, and this constitutes Romberg's sign.

Muscular strength is intact in all her limbs, but when she is told to shut her eyes and put a glass to her lips she goes wide of the mouth. Let her try to place the left heel quickly on the right knee—she cannot do it! These are the means which enable us to diagnose ataxy at the onset.

We may add that the ankle and knee jerks are abolished and those of the upper limbs are very feeble. There is nothing wrong with objective sensibility, but the area of the ulnar nerve is hyperæsthetic. Lastly, examination of the eyes reveals two signs of the greatest importance, the Argyll-Robertson pupil on the one hand and, on the other, traces of old standing optic neuritis, manifested by irregularities and pallor of the optic nerves. One little detail to complete the picture—for no point must be overlooked—she has false teeth and she tells us that some years ago her teeth became loose and in a short time came out though not decayed. This shedding of the teeth is evidence of a trophic disturbance comparable with shedding of the nails, perforating ulcer, etc., and it is a comparatively rare sign of the disease under consideration. In view of these various signs we need not hesitate to diagnose Duchenne's disease, but it is not yet true locomotor ataxy for the patient is still in the pre-ataxic stage.

Now, among the abnormal manifestations of tabes are certain cerebral symptoms which as a rule occur during the præ-ataxic period, *viz.*: apoplectiform or epileptiform attacks which may resemble complete essential epilepsy or Jacksonian epilepsy, hemiplegia or localised paralysis, which have this in common that they all exhibit a tendency to clear up rapidly and spontaneously. This fugitive character justifies us in putting them down to vaso-motor disturbance, possibly dependent upon medullary or protuberous lesions of tabes.

However this may be, these symptoms suggest a malady affecting the cerebrum. You cannot but be struck by the unlikeness of the principal medullary type of tabes. If you bear in mind the extremely insidious invasion of these symptoms you will understand how easy it is to make a mistaken diagnosis of some cerebral disease, cerebral syphilis, etc.

There is one other point to which I must call attention; among the somatic troubles of the prodromal period of diffuse meningo-cephalitis one of the most important is the sudden, unexpected supervention of epileptiform attacks, either general or local. These may be motor or sensory, but the latter possess a special significance and must be looked upon as one of the most characteristic signs of the onset of progressive general paralysis.

Now in this woman we shall find that certain symptoms accompanied her attacks of sensory epilepsy which escaped our attention just now, *viz.:* a little trembling of the tongue a little "mouthing" and some blurring of words. Though but slight these signs must make us hesitate awhile as to the diagnosis. I should not be surprised indeed, if, within the near future, this woman gave unequivocal signs of general paralysis.

This is not the moment to enter upon the discussion of the relationship of general paralysis to tabes. This view was first suggested in France by Baillarger, and the co-relationship was set forth by my pupil, Dr. Nageotte, in his thesis, under the term "Cerebro-Spinal Tabes," a term which Dr. Fourrier gives to cases in which the two manifestations run their course together.

We will now pass to the second patient, a strong man, æt. 39, who is still employed as a messenger. He comes to us for chronic, recurring ulceration of the soles of both feet, which started eight years ago. When 31, he had a perforating ulcer on the right little toe which led to painful suppuration and was followed by the shedding of two phalanges. Five years ago another ulcer formed on the first phalanx of the left big toe. There is another on the metacarpo-phalangeal joint underneath. Another similar ulcer, this time associated with symptoms of general infection, occurred on the left little toe, and the third phalanx came away. A fifth ulcer started in 1902 on the right big toe, necessitating amputation and last year a sixth made its appearance on the fifth left metatarsal bone. There is very distinct perforating ulcer on the left foot, there is a circular loss of substance with punched-out edges made up of stratified epithelium, and the base is irregular and granular and is bathed in scanty muco-purulent secretion. There is no inflammatory reaction round the ulcer, it is everywhere anæsthetic, and the sound touches bare bone and can be pushed right into the joint, the synovial membrane whereof is thickened and granular. Then, too, the feet are cold and livid and the skin is covered with cold sweat. There is some œdema in the left leg and the skin of both feet shows a tendency to hypertrophy.

Since Nélaton first described what we now know as perforating ulcer, its pathogenesis has undergone many modifications. Without troubling you with the history of the question I may state that the affection is no longer looked upon as a purely local lesion due to mechanical causes. Some, Péan, for instance, ascribe it to arterial lesions, others, like Poncet, Duplay, and Morat, believe it to be of nervous origin and attribute it to degenerative changes of the nerves. The latter view is the one that holds the field at present, so that we need not waste time in the endeavour to elucidate a mechanical ætiology. That prolonged pressure may be a determining and localising factor is but probable in view of the improvement that follows rest, but the fundamental trophic disturbance must be looked for elsewhere. First we must look to diseases of the spinal cord, especially tabes, then infantile paralysis, Freidreich's disease, myelitis, syringomyelia, etc. Perforating ulcer may even be one of the trophic disturbances affecting the foot consequent upon medullary compression, as in Pott's disease, spinal tumours and spina bifida. Sometimes we must go even further afield to diffuse meningo-encephalitis. Not uncommonly the cause is a primary or secondary affection of the peripheral nerves. All nervous lesions may give rise to the same trophic disturbances—wounds, bruises, incised wounds, various compressions, all kinds of neuritis, whether infective or toxic, changes in nerves consequent upon varicose dilatations, and phlebitis of the intra-nervous veins and so on.

Still more, the ætiological factor in the production of perforating ulcer may be even more general, for it may be due to a constitutional infection such as leprosy, mercury or alcohol, to a diathesis such as diabetes or a general dystrophy such as arteriosclerosis. The lesion may occur elsewhere than on the sole and under aspect of the toes, and you must not be surprised to find it now and again on the palm, in the sacral region, over the coccyx, etc.

Let us now discuss the ætiological problem of perforating ulcer. It is only complicated in appearance and you will soon grasp the nature of the lesion. If we question the patient we find that at thirty-four he was under medical care for grave pulmonary congestion. Seventeen years ago he had a chancre with the usual sequelæ and he underwent several courses of mercurial treatment. His tongue testifies to past syphilitic manifestations, so that there can be no doubt of the syphilitic nature of the infection. He tells us without being questioned that at twenty-five he had short sharp pains in both legs which were put down to rheumatism—a very common error against which you should be on your guard. Having reached their maximum intensity these pains subsided in the course of a few years, a very troublesome sensation of girdle pain and thoracic constriction taking their place. These in their turn disappeared, and for some years all that he complained of has been of both lower limbs.

Pains of this kind, dating back some fourteen years, coming on in short, sharp crises, at once makes one think of commencing locomotor ataxy. But the knee jerks are present though dull, and even the ankle reflex, which is usually the first to disappear, can still be elicited, though not so active as normal, and less marked on the left side than on the right.

At first sight it would be hard to say that the patient is ataxic, he can turn round promptly and can walk up or down stairs, etc., without hesitation. Yet when he shuts his eyes there is some unsteadiness of gait, especially in starting and stopping, and he throws out the leg. He sways when standing up and cannot remain erect, *i.e.*, Romberg's sign.

There is no loss of muscular strength, yet his arms and legs are peculiarly flaccid and flexion movements are unduly ample, in short, there is hypotonus. Carrying our examination a step further we find that he has had some trouble in respect of micturition for months past. He is often obliged to wait awhile and to strain to set it going, sometimes, indeed, he is obliged to squat in order to empty the bladder. At other times there is a slight incontinence, not only of urine, but also of the fæces. Sexual desire is lessened, yet he has frequent nocturnal emissions. Testicular sensibility is lessened. All these symptoms are important in view of their grouping, but we now come to something much more significant, *viz.:* the results of examination of the eyes. There is no evidence of any mischief of the fundus, no disturbance of external movement (never any diplopia), but there is obvious inequality of the pupils and a diminution of the pupillary reflex to light.

These then are the principal symptoms and, as you have seen, it has been necessary to look for them pretty closely; this fact may explain how it is that his condition has escaped diagnosis for fourteen years or so.

Apart from the trophic symptoms which brought the patient to us I would lay special stress on four cardinal symptoms; the lightning pains, Romberg's sign, the urinary troubles, and the state of the internal muscles of the eye. Three of these symptoms occurring together would suffice to establish the diagnosis, and when we have the fourth it becomes a certainty. This man, although the disease has existed for fourteen years, is still in the præ-ataxic stage. This stage has been of long duration and it may last much longer. The special feature in this case is the tendency to perforating ulcers. This is a case of trophic tabes in which the nutrition of the lower limbs is very markedly modified. The joints of the foot share in these changes, one of them especially, the metacarpo-phalangeal joint of the left big toe, is much enlarged and grates on being flexed. Both feet are much flattened and this deformity, as you know, is often due to tabes, but it is only the outcome of trophic disturbances of the joints, allowing of relaxation of the ligaments and fibrous bands that normally maintain the arches of the foot. As a matter of fact I do not think that tabes need be invoked in the present instance for the deformity dates back to early life and he has been subjected to long standing and multiple fatigues. Moreover, he had, even young, a well-marked tendency to varicose veins. His father suffered from arterio-sclerosis, so that the conditions were such as to favour nutritive disturbances of the lower limbs. From its onset the disease found a ready-prepared soil and the early nerve troubles soon gave rise to trophic disturbances. Such cases are by no means rare, in fact, I would impress upon you that these trophic disturbances are not only a possible complication of confirmed tabes, but are often a very early, nay initial, symptom of the disease. You will see, therefore, that we must not concentrate our attention too exclusively on the state of the reflexes.

And now, in order to bring clearly before you the remarkable polymorphism of tabes. I will show you a third patient, a woman, æt. 33 years, without any interesting pathological antecedents. Married at fifteen, she was divorced, and re-married at twenty-eight. She only had one child, who died at two months of age. The confinement was followed by some obscure, probably infective, uterine trouble which did not pass off, and four years ago the adnexa were removed. Advantage was taken of the opportunity to remove the appendix because she suffered at the time from vomiting. The genital troubles subsided, but the vomiting persisted so that the appendix was evidently not to blame.

Six years ago, when æt. 27, she first noticed severe pains in the legs—a stabbing, radiating pain, "as quick as lightning" as she describes it. The pain recurred daily just before going to bed and prevented sleep. The attacks lasted about half an hour and then suddenly subsided. Here again, and I must insist upon the fact, the pain was diagnosed as rheumatic and treated as such. Then came on the vomiting, at first easy and bilious, it occurred at any hour of the day and had no obvious connection with meals or with the kind of food. Note that the vomiting was absolutely painless. For four years the vomiting recurred in crises, at variable intervals. Eighteen months ago (at 31) the attacks began to be accompanied by severe pain in the back, chest and epigastrium. Sometimes the pain was stabbing, like that of an ulcer, sometimes in the form of girdle pain, sometimes constrictive. The attacks often coincided with the periods, which is often the case in these visceral crises. At first the attack lasted two or three days, then a week, and recently a fortnight. While it lasts the patient avoids taking food and, curiously enough, does not seem to feel any the worse for the abstention, though of considerable duration; in short, she seems to have lost the sense of hunger. The painful attacks are often followed by diarrhœa. She lost flesh and became the subject of intense nervous depression. The only thing that did her any good was morphia, and she drifted into the morphia habit. I shall have occasion to point out, shortly, the part played by these injections in bringing about a repetition of the gastric troubles.

Moreover the pains in the lower limbs had never quite left her, indeed, they had also made their appearance in the upper limbs, especially on the internal, ulnar aspect, the thenar eminence and the little finger. For five years these various pains were the sole manifestations of the disease. But during the past year she noticed that unless she paid particular attention to her feet in walking she was apt to stumble and she found going upstairs very difficult. She is subject to a frequent desire to pass water without necessity, while at other times she is unable to retain it. On more than one occasion she has passed motions involuntarily.

So much for her history; you will already have made up your minds as to the diagnosis, but we will proceed to corroborate it. She tells us that she is unable to walk in the dark, and you have only to watch her trying to walk with her eyes shut to see how matters stand. The ankle reflexes are abolished, the knee-jerks are diminished, the pupils are unequal, the left (the larger) being quite insensible to light, while the right is sluggish. The pupillary reflexes, however, respond to accommodation; in short, she exhibits the Argyle-Robertson phenomenon.

Obviously it is a case of tabes. That is easy enough to say now, but was it equally so a few years ago? Every physician is aware of the fact that gastric troubles are among the symptoms of the præ-ataxic period, but what is perhaps less clearly recognised is that this symptom may usher in, and for a long time remain the sole and only feature of, the clinical picture. How many times have the gastric manifestations given rise to an erroneous diagnosis of gastric ulcer, or gastritis with pyloric stenosis or intermittent attacks of hepatic or nephritic colic? It is very easy to make this mistake, all the more so because it is customary to comprise all tabetic stomach troubles under the term "gastric crises." The student always looks for the picture of the grand tabetic crisis and loses sight of the diversity of form in which it may present itself. In this case it came on as painless vomiting, in another it may be gastralgia without vomiting, "stomach cramps"—there is only one feature in common, *e.g.*, their periodical evolution, their recurrence in attacks which become more and more frequent, often monthly, corresponding with the menstrual periods.

This case enables me to direct attention to a feature which was clearly defined some years ago by Roux in his thesis, *viz.*: the degree in which these attacks are influenced by anterior dyspepsia, by the nature of the food and by medicinal gastritis following the administration, by the mouth or subcutaneously, of sedative remedies. Under this double influence the characteristic features of the tabetic crisis—its suddenness of onset and subsidence—may be lost, so that the crisis is disfigured so to speak. I need hardly insist upon the disastrous effects of repeated injections of morphine on the stomach. The more frequent the injections the shorter is the interval between the attacks and the more severe are they. A large eater, an old-standing dyspeptic, this patient stood every chance of her tabes commencing by the stomach. Under the influence of her medicinal intoxication the attacks become more protracted. Nutrition was gravely interfered with and morphia no doubt had much to do with the intense nervous depression that followed.

Our first care then must be to demorphinise the patient reserving the drug for the severest attacks of pain. We must put her on milk diet for a few days and then a lacto-vegetarian diet.

The best means at our disposal to calm the pains and visceral manifestations is the injection of nitrite of soda. For ten days following inject one cc. daily of a 2 per cent. solution of the salt, then ten days rest, then two cc. daily followed by a period of repose, then ten days with three cc. daily, and so on until four cc. daily is being given. This treatment has yielded very satisfactory results, but not in every instance. In the event of failure we must not leave these unhappy patients to their fate, we may employ electricity, baths of ultra violet rays applied to the loins, &c.

AN outbreak of infectious disease has occurred in rural Essex. It is believed to have been caused by the introduction of London poor children on holidays. As many of the affected children as can be got into the isolation hospital there are being so treated, the remainder being kept at their country lodgings. Efforts are being made to ascertain the liability of the charity organisations which sent the children into Essex, and that of the children's parents, but it is much to be hoped that this unfortunate *contretemps* will not affect the good work of the children's holiday funds.

ORIGINAL PAPERS.

SOME OBSERVATIONS ON
THE USE OF CALCIUM SALTS.

By S. J. ROSS, M.D., Vict.

Surgeon, Out-Patients' Bedford and County Hospital.

I NEED only in passing, remind your readers of the debt of gratitude we owe to Professor Wright and Dr. Ringer for the pioneer work they have done with reference to the value of calcium salts as therapeutic agents.

My object in writing these notes is to draw the attention of busy general practitioners to the value of calcium salts in certain common and often troublesome conditions.

Childblains.—I have employed calcium chloride, gr. x., thrice daily and given in a tumblerful of water, in ten cases with complete success. The drug was given for two days, then omitted for three days, and administered again for two days. The average duration of treatment was fourteen days.

Ulcers of the Leg.—I have used calcium iodide, gr. iij., thrice daily in fourteen cases; combined with rest and low diet. In each case the drug was administered intermittently, and in each case the ulcer healed soundly and rapidly. Locally I employed Ung. Hydrarg Ammon. Seven of these cases were varicose ulcers. The ages of the patients ranged from 17 to 86 years. In one case the patient had remained in bed for two months but the ulcer refused to heal. After the commencement of the calcium iodide treatment the ulcer rapidly improved, and was soundly healed in three weeks. I have noticed that for the first few days of this treatment the ulcer discharges more freely than before this treatment was commenced.

Epistaxis.—I had a very severe case of epistaxis occurring in a patient, æt. 74 years, with markedly atheromatous vessels and high tension pulse. He was freely purged, sent to bed, and placed on milk diet. His left nostril, from which the bleeding took place, was plugged with a strip of cyanide gauze soaked in adrenalin solution. Hæmorrhage persisting, I gave the patient calcium chloride, gr. xv., twice; the hæmorrhage ceased and did not recur.

Painless Œdema of the Ankles.—A youth, æt. 20 years, complained of swelling of both ankles. His heart and urine were normal. I gave him gr. xv. of calcium chloride thrice daily for three days and the œdema cleared up. Two months after this he presented himself with the same condition, which yielded to similar treatment.

Tertiary Syphilis.—A man, æt. 47 years, had a syphilitic perforation of his hard palate. I gave him potassium iodide, but this he could not tolerate, symptoms of iodism quickly appearing, I then put him on calcium iodide, gr. iij., thrice daily. This he took without inconvenience and continuously for two months, at the end of which time the perforation had healed.

Menorrhagia.—A lady, æt. 30 years, who was subject to attacks of epistaxis and erythema nodosum had a very profuse period. She told me that her skin very readily bruised. I ordered gr. xv. of calcium chloride ter in die, and the hæmorrhage ceased. Nine months after this she had a similar attack checked by the same drug.

A case of Pneumonia with free hæmoptysis.—I had a case of pneumonia in a patient, æt. 45, a marked alcoholic. The left lung was solid. He expectorated blood freely. I gave him calcium iodide, gr. iij., thrice daily for three days and the hæmorrhage ceased. The patient ultimately recovered.

Remarks.—These few cases have impressed upon my mind the value of this drug in the conditions I have indicated. The only unpleasant symptom complained of in three cases was nausea, which was stopped by increasing the dilution of the drug. Syrup of orange in drachm doses renders the mixture more palatable than if it be given in water only. There are many other conditions in which calcium salts have been successfully employed, *e.g.*, rickets, hæmaturia, hæmatemesis, erysipelas, erythema nodosum, functional albuminuria, hæmophilia, in gall bladder operations where adhesions are anticipated and as a result free hæmorrhage (I can vouch for its value in these cases when given twenty-four hours before operation), and in the rashes following serum injection.

Calcium salts are said to raise the blood pressure. They certainly did not raise the blood pressure of the case of epistaxis I have cited. Had the blood pressure been raised to any appreciable extent the result would have proved disastrous.

I have personally been most impressed with the beneficial action of calcium salts in the cases I have cited. To those of your readers who have not tried them, I say try them. To those who have tried them let me ask them to add their experience to mine, as an ounce of experience is of more value than a pound of theory.

THE DEFINITION OF BLINDNESS IN CHILDREN: ITS CAUSES AND PREVENTION (*a*).

BY ADOLPH BRONNER, M.D.

Senior Surgeon, Bradford Royal Eye and Ear Hospital; Laryngologist, Bradford Royal Infirmary.

THE definition of blindness, as generally accepted, is that the vision of both eyes is so bad, that the patient cannot see well enough to find his way about in daytime, or count his fingers at twelve inches. Even adopting this very narrow point of view, we find that in 1901 there were no less than 25,317 blind people in England and Wales, or 771 to every million of the population. These figures are not very accurate, as there are a large number of blind persons who do not acknowledge that they are blind, and, on the other hand, a fair number who are blind, but whose vision could be improved by operation or treatment. Of children under fifteen years, 423 out of every million of that age are blind. But I think that in dealing with this very important question we should not only include the blind, but also all children who suffer from defective eyesight, certainly those who do not see well enough to read ordinary school books. If this were done, the numbers would be very much larger. And, surely, from a practical point of view, a child who cannot see to read is nearly as badly off as a child who is quite blind. I should suggest that some universal standard of defining the various degrees of weak-sight be adopted for all countries, so that our statistics may be of a uniform nature. Vision of 6/9 to 6/12 to be called "fair sight," 6/18 to 6/24 "weak sight," 6/36 to 1/60 "bad sight," and "less than 1/60" blind. It would then be easy to divide the children into different classes for teaching purposes. At present there are generally only two classes, for the normal-sighted and for the

---

(*a*) **Read before the International Congress on School Hygiene, London, August, 1907.**

blind. There certainly ought to be at least one intermediate class for these children who are not blind, but can see a little. In time some of these could be drafted into the first class, and some into the third, or blind class.

Most cases of blindness in children are due to disease, about 80 per cent. Magnus examined 3,206 blind children and found that in 17 per cent. the blindness was congenital or due to malformation of the eyes, mostly hereditary or due to congenital syphilis; in 33 per cent. to diseases of the eyes, including 23.5 per cent. which were caused by purulent ophthalmia; in 8 per cent. to trauma; while in 33 per cent. it was the result of some general disease which had affected the eyes; in 7.5 per cent. to small-pox. Roughly speaking, 8–10 per cent. are due to congenital syphilis. Cases of trachoma, or granular lids, are very rare in this country. Harman could only find five cases in 70,000 English children. For many years, 1869 to 1900, contagious conjunctivitis was very prevalent in the Hanwell schools, and caused many cases of blindness. This was, however, stamped out by the untiring energy of Dr. Stephenson.

These statistics only include children who are quite blind, and no notice is taken of those with defective eyesight, or who are blind on one eye only. Thus, those cases of progressive short-sight, which are so often met with in school children, cases of ulceration and disease of the cornea, which are so very common and cause defective eyesight, and many others, are not included. There are 25,317 blind people in England, but how many are there with defective eyesight? At least half a million. Even to non-medical men, these figures are appalling, and one naturally asks, cannot something be done to prevent so many unfortunate people from becoming weak-sighted or blind?

Cohn and others have examined 1,000 blind people, and assert that in about 40 per cent. of these, the blindness could have been prevented. That means that there are more than 12,000 blind people in England today who need not be blind, but who should be able to see as well as you or I. And tens of thousands who are suffering from defective eyesight which could have been prevented.

1. CONGENITAL BLINDNESS.

Congenital blindness could, to a great extent, be avoided, if persons suffering from hereditary diseases of the eye, chiefly cataract, optic atrophy, and retinitis pigmentosa, were not allowed to marry. When both parents are born blind, often all the children and their offspring become blind. In Bradford there is a family of blind parents with five blind children, all of whom were in the workhouse. A large number of cases of congenital blindness are due to syphilis, and many cases of blindness which occur in early childhood are caused by the same disease. These could, to some extent, be avoided, if every case of syphilis were treated for two years, and not allowed to marry during that time. An American physician has recently advocated State regulation of marriage, through a Board of Guardians. He predicts that if this is not done, "Americans will in time be chiefly idiots and imbeciles."

2. INFANTILE PURULENT OPHTHALMIA.

Purulent ophthalmia of infants is a very common cause of blindness. No less than 23.5 per cent. of all cases of blindness in children, according to Magnus, are due to this disease, and 72 per cent. of all cases under one year of age. It is an inflammation of the inner part of the lids, characterised by a copious creamy discharge with swelling of the eyelids. It causes ulceration of the cornea (transparent front part of the eye), with consequent opacity, or perforation and complete loss of the eye. It is due to direct infection at the time of birth, or at the dirty hands of the midwife, and caused by a germ called the gonococcus of Neisser. Fortunately it is not as common as it used to be. Formerly 30 to 50 per cent. of all babies, at least in the lying-in hospitals, became affected, now only 0.25 to 0.1 per cent. Thanks to improved methods of treatment, purulent ophthalmia is not nearly so dangerous as it was some years ago, when 40 to 50 per cent. of all cases became blind. Now only about 4 per cent. lose their sight, and 15 to 18 per cent. have defective vision. The best methods of treatment are, as soon as the eye becomes red or there is the slightest discharge, to inject 2 per cent. nitrate of silver drops between the opened lids, three times a day, or, better still, 10 to 20 per cent. protargol or argyrol drops every one or two hours, or peroxide of hydrogen drops, or to insufflate airol powder, and, in some severe cases, to paint the everted lids with 10 per cent. nitrate of silver; also wash out the eyes with 1 in 3,000–5,000 perchloride of mercury lotion (warm), and with a glass irrigator, and not with a dirty sponge, as is so often done. It is very often difficult to get the drops and lotion between the lids, as these are very swollen, and it requires the help of a skilled nurse. All cases, therefore, which cannot be carefully treated at home, should be admitted into hospital at once. Most cases occur in the private practice of midwives. At last a Midwives Bill has been passed, and many of those dirty, disreputable old women who called themselves midwives have disappeared, let us hope for ever. According to the rules of the Central Midwives Board, "every midwife must decline to attend alone, and must advise that a registered medical practitioner be sent for, whenever there is inflammation to even the slightest degree of the eyes and eyelids." They, however, very frequently do not do so. Last year at the Bradford Royal Eye and Ear Hospital I saw no less than five cases of purulent ophthalmia, in which the midwife had treated the eyes for several days and not sent for a doctor. Three of these children are now hopelessly blind. The rule should be made much more stringent, and the midwife should be obliged to send for a doctor within twelve hours, and if she neglect to do so, should be most severely punished. In America, in some States at least, they are fined up to 100 dollars, and get up to six months' hard labour. Why cannot we do this in England?

The parents, especially the mother of the child, should be told of the great danger of this disease. Some years ago the Committee of the Bradford Royal Eye and Ear Hospital communicated with the Registrar-General, drawing his attention to the prevalence and danger of purulent ophthalmia, and suggesting that every registrar should be requested to give a printed card with instructions to every person who registered a birth.

"*Instructions Regarding New-Born Infants.*"

"If the child's eyelids become red and swollen, or begin to run with matter within a few days after birth, it is to be taken to a doctor immediately. The disease is very dangerous, and if not at once treated, may destroy the sight of *both* eyes."

The reply received was very characteristic. "A similar request has been made three years ago by the Ophthalmological Society, but it is impossible to adopt the suggestion, because the registrars are not salaried officers, but are paid by fees for the registration of each birth, and cannot be asked to undertake a duty, the distribution of such cards, unless they are offered some additional fee." Thanks to the kindness of the local registrar, such cards were for some years distributed in Bradford. Similar slips have also been issued by the Committee of the Gardner's Trust for the Blind, 53 Victoria Street, Westminster. I do not know of any Trust which fulfils its duties in such an efficient manner as this Trust. Mr. Wilson, the Secretary, is always pleased to give advice or help in any matter concerning the blind, and the prevention of blindness.

As the Registrar in Bradford is no longer willing to distribute these slips, the Committee of the Hospital send some to every midwife working in the district, and also cards with special directions. These are also distributed among the out-patients of the hospital.

3. DISEASES OF THE EYE.

A large number of cases of defective vision and blindness are due to disease of the cornea and other parts of the eye. Ulcers and inflammation of the cornea (which are very common in children), if neglected or not carefully treated, cause opacities, more or less marked. The longer the ulcer lasts and the more frequently it recurs the more dense will the opacity become, and the more defective the sight. Every case which cannot be properly attended to at home should be at once admitted into hospital. The same applies to disease of such delicate structures as the optic nerve and retina. These require most energetic and careful treatment, and, if neglected, cause permanent blindness. If all these cases which occur in the homes of the poor (where careful nursing is often impossible) were admitted into hospital, thousands of children would be saved from defective vision and blindness. Unfortunately, however, there is not enough accommodation in our hospitals. In the West Riding of Yorkshire, with about 3,000,000 inhabitants, there are not more than two hundred beds available for eye cases, and these are nearly all filled with operation cases. At the Bradford Royal Eye and Ear Hospital we have only forty-five beds, and draw patients from a large part of the West Riding. Last year 1,100 operations were performed, so that we had very few beds available for cases of disease.

4. SMALL-POX.

7.49 per cent. of the cases of blindness, according to Magnus, are due to small-pox. Before the days of vaccination 30 to 40 per cent. of all cases of blindness were caused by this awful disease. In 1901 no less than 980 cases of small-pox in children of five to thirteen years were recorded. Of the 230 children who had been vaccinated (some probably most inefficiently) only three died, whereas of the 750 who had not been vaccinated, no less than 141 died. In spite of these and many other equally convincing figures, we find that our wise Government is affording still further facilities for non-vaccination. Fanatics are allowed in and out of Parliament to abuse vaccination and incite stupid and ignorant parents not to have their children vaccinated.

5. EXAMINATION AND CARE OF THE EYES OF SCHOOL CHILDREN.

We now come to the important question of the examination of the eyes of school children. The State compels all children to attend school, and it is, therefore, clearly also the duty of the State to see that these schools are properly conducted, and that the children are in a fit condition to make use of them. All schools should be under medical supervision, and every child should be examined to see if it is fit to attend school. Bradford was one of the first to appoint a School Board medical officer, and Dr. Kerr was elected. Unfortunately for Bradford Dr. Kerr was soon called to London as the medical officer to the London School Board. I hope that everyone present, who takes an interest in school work, reads Dr. Kerr's annual reports to the Education Committee of the London County Council. They contain most valuable and interesting information on the medical aspect of our schools.

The vision of every child should be tested as soon as it can read large letters. This can be done by the teachers. Those whose vision is less than 6/9 should be examined by the medical officer, and a register kept of all cases. The parents should then be informed that the eyes of the child are defective, and asked to send it to a doctor, or, if the parents are poor, to a hospital. According to Dr. Kerr's statistics no less than 10 per cent. of the London school children have defective eyesight. The majority of these cases require glasses. If the parents neglect to send the children to a doctor or to provide glasses for them they should be compelled to do so. Dr. Kerr says that in London, "only the minority of these cases secure any further treatment." How different it is on the Continent! At Mannheim, of 250 children whose eyes were reported as defective, all, with the exception of nine, had been seen by a doctor within seven days. Many parents are too poor to buy glasses. These should be supplied by the local authorities. But they refuse to do this. The result is that hundreds of children attend our schools who cannot see well enough to profit by the teaching. In London a voluntary association has been formed, and they supply ordinary spectacles at 10d. a pair, about one-fourth to one-tenth of what is generally charged. It has always struck me as very absurd that medical men examine the eyes of the poor at the hospitals gratuitously, and that these patients often then fall into the hands of unscrupulous opticians, who make a larger profit on the glasses than the consultation fee of an ordinary medical man would have been. A large number of school children and others fall into the clutches of advertising quacks, who not only rob them of their money, but ruin their eyesight by supplying wrong glasses. In my opinion the best method of dealing with the children of the very poor would be, that they be examined at the schools by specially qualified medical men at the expense of the local authorities, who should also supply glasses free of charge when the parents cannot afford to pay for them.

All children with defective eyesight should be examined at least once a year, and a record of each case kept. This is specially important in cases of short sight, or myopia. Often the vision becomes rapidly worse, and special attention should be paid to these children, to see that they are supplied with proper glasses, and do not bend their heads when reading and writing. It is absolutely scandalous to see how the children sit at some of our schools when writing. They have their heads down, nearly touching the desk, often supported on a hand, and held sideways. The desks are frequently most unsuitable, and the light and ventilation most defective. Luckily myopia, especially the severe form, is not very common in England. At the Bradford Royal Eye and Ear Hospital last year, out of 6,000 patients, 1,720 were far-sighted and only 582 short-sighted, and very few of these were of the progressive type.

The points to which I should particularly have liked to draw attention in this very incomplete paper are :—

1. That in the statistics of blind children we should also include those with defective sight, certainly those who cannot see well enough to read ordinary school-books, and sub-divide these cases into the following classes :—

(*a*) Fair vision up to 6/12.
(*b*) Weak vision 6/18 to 6/24.
(*c*) Bad vision or nearly blind, 6/36 to 1/60.
(*d*) Blind, 1/60 and under.

That in all large schools special classes should be formed for children with defective vision, and that they should not be taught with the blind children.

2. All midwives should be obliged to notify every case of purulent ophthalmia to a doctor within twelve hours. Should she fail to do this, her licence should be withdrawn, and she be fined not less than five pounds.

3. The parents should be warned of the great danger of purulent ophthalmia, by means of pamphlets or cards, which should be given by the registrar to every person who registers the birth of the child. The midwives should also be supplied with similar cards.

5. Greater facilities should be afforded for the practical and theoretical teaching of ophthalmology at our medical schools, and practical and written examinations should be made compulsory.

6. Abolition of the conscience clause in the Vaccination Act. Punishment of all those who publish misleading statements on vaccination.

7. The eyes of all school children should be periodically examined by an expert. A record kept of all cases with defective vision, and these to be examined every year. Parents should be compelled to see that all such children are treated and supplied with glasses, if necessary. The poor children should be examined at the schools, and supplied with glasses free of charge.

8. Every case of reported blindness should be examined by a medical man, to see if nothing can be done to improve the vision.

9. People suffering from hereditary blindness should not be allowed to marry. No person who has had syphilis should marry for at least two years after he has contracted the disease.

CHRONIC SUPPURATIVE DISEASE OF THE MIDDLE EAR,

WITH SPECIAL REFERENCE TO SURGICAL TREATMENT.

By E. MALCOLM STOCKDALE, M.R.C.S.,

Assistant Surgeon, Liverpool Eye and Ear Infirmary.

JACOBSON, in the section dealing with surgical anatomy in Morris' *Treatise on Anatomy*, refers to otitis media as "this frequent and fatal disease;" and the statement of Wilde that "when a discharge from the ear exists we can never tell how, when, or where it will end, or to what it may lead," still expresses the prognosis. The discharge is a constant source of annoyance to the patient; and the time spent in attending for treatment over a long period, with the expense of drops, lotion, etc., may be a serious matter to the working-man, so that after a while he is likely to discontinue treatment, and run grave risks of developing dangerous complications.

In almost every case this disease has its origin in the mucous membrane of the nose or naso-pharynx, the pyogenic organisms extending to the tympanum along the Eustachian tube. They may be conveyed by the blood-vessels, the lymphatics, or may perhaps spread in the form of a superficial catarrhal inflammation. The result of this invasion is that the middle ear becomes a culture chamber for various bacteria, the micro-organisms most commonly present being streptococci, staphylococci, or pneumococci. These cause local pathological changes, varying in their nature and extent. The mucous membrane alone may be attacked, becoming hyperæmic, œdematous, and exuding a muco-purulent or purulent dischage, usually the latter. Later. polypi may form, or the mucous membrane become pulpy and thickened, or replaced by granulation tissue. The tympanic membrane may be destroyed, the ossicles shed, the labyrinth be invaded, and caries or necrosis of parts of the temporal bone may also occur. In certain cases the disease may remain localised to the tympanum, but in almost all, the mastoid antrum sooner or later becomes involved.

Again, the mastoid antrum may be seriously diseased, but the tympanum not damaged beyond recovery. Relating to the extent of the destructive changes produced, the virulence of the infection is often a more important factor than the duration of the suppuration. Cases developing during an attack of scarlet fever are frequently of a severe nature.

The type of case which I wish to discuss is that in which the chief symptoms are a purulent discharge of some duration from the external auditory meatus, with more or less impairment of hearing, and sometimes pain. In cases of this nature, are we to stand by until urgent symptoms or dangerous complications arise; or. finding conservative treatment of no effect, shall we interfere? I am convinced that when the charge persists in spite of antiseptic treatment carefully carried out (the nose and naso-pharynx having received attention if necessary), surgical interference is called for. We should not wait till the mucous membrane lining the tympanum or mastoid antrum is disintegrated, and perhaps the hearing destroyed.

When should operation be advised? The virulence of the infection and the nature of the lesion present are the factors in deciding this question, but a discharge lasting three months under conservative treatment usually calls for surgical assistance.

What form of surgical procedure should be employed?

Before a definite answer can be given, it is necessary to ascertain as far as possible the character of the pathological changes present. The following points should be investigated:—

(1) The condition of the tympanic membrane; (2) the presence or absence of the ossicles; (3) the presence or absence of granulations or (aural) polypi; (4) the amount and character of the discharge; (5) whether caries or necrosis exists. Since the character and position of the chief lesion varies, the nature of the operation required can only be decided after investigating the local condition. If the disease is localised to the tympanum, and can be dealt with efficiently through the external auditory meatus, there is no object in opening the mastoid antrum, nor should removal of the ossicles and drum membrane be undertaken if treatment of the antrum alone would lead to recovery.

The chief operative measures at our disposal may be considered under the following headings:—

(1) Intra-meatal, which are performed through the external auditory meatus.

(2) Post-aural, in which an incision is made behind the ear and the soft parts *drawn forwards*.

Intra-meatal Operations.—Aural polypi are best removed by means of a small snare, carrying a fine pliable wire. The loop should be passed over the polyp and gently manipulated towards the root of the pedicle, which should be cut through, as roughly tearing the growth away may cause serious damage, since it is impossible to predict its point of attachment.

Granulations projecting through a perforation in the tympanic membrane should be removed by means of a small aural curette, the field of operation being clearly illuminated, so that each movement of the curette is clearly observed and has a definite purpose. Removal of polypi or granulations will often arrest the discharge and effect a cure. The following case is of interest in this connection.

A man, æt. 29, had suffered from otorrhœa and deafness of the left ear for eight months. One evening he coughed and something was discharged from his ear, followed by hæmorrhage. He carried the specimen to his medical adviser (Dr. Holmes, Anfield), who informed him that it was a polypus. When I examined him six days later his ear was dry and the perforation in his tympanic membrane appeared to be healing. A fortnight later no perforation could be seen, and his hearing was greatly improved by inflation with the Eustachian catheter. He has apparently cured himself, having discharged his polyp by a forcible inflation through his Eustachian tube. Still operating through the meatus, ossiculectomy calls for notice.

Ossiculectomy.—Excision of the tympanic membrane, the malleus, incus, and perhaps the outer wall of the attic, with the removal of any granulation tissue, is of value in some cases, being a much less severe procedure than any post-aural operation, but its application appears to me to be limited, since in almost all cases of chronic suppurative otitis media the mastoid antrum is involved, and in many the ossicles have been previously lost, as a result of the suppurative process. My experience of this operation is limited to four cases. In those selected the discharge was small in amount, the tympanic membrane thickened, and the hearing greatly impaired. The discharge has been arrested in all, and in two the hearing is somewhat improved.

POST-AURAL OPERATIONS.

Heath's Operation.—In the *Lancet* of August 11th, 1906, under the title of "The Cure of Chronic Suppuration of the Middle Ear without removal of the Drum or Ossicles or Loss of Hearing," Mr. Charles Heath, of London, described an operation and published the result in ten cases. In all, the hearing power was improved. Briefly stated, the opening and final stages of this procedure are similar to the radical mastoid operation, the essential points of difference being that the tympanic membrane, ossicles, attic, and antro-tympanic passage are left intact. Details of the after-treatment are given.

The title of this paper might convey the impression that the removal of the ossicles and tympanic membrane results in loss of hearing. This, however, is not the case, excellent hearing being retained if the receptive mechanism is in sound condition. It has even been suggested that the ossicles and tympanic membrane are chiefly protective in function, the conduction of vibrations being of secondary importance. Heath's operation commends itself to me as valuable in those cases where the tympanum and antro-tympanic passage are not seriously disorganised, the chief seat of the suppuration being in the mastoid antrum. My experience of this operation is limited to two cases, as in most of those placed under my care the ossicles had already been lost, or the lining membrane was so diseased that the radical operation appeared necessary.

Case I.—R. R., boy, æt. 4 years; discharge from right ear three years; commenced during an attack of measles. Hearing? Heath's operation, November, 1906. Antrum found to be very large, and communicated with some superficial mastoid cells. The antro-mastoid cavity was filled with stringy pus. Last seen, March 1st, 1907. Soundly healed. Hearing good. Watch 12'.

Case II.—E. J., a girl, æt. 10, was admitted to the Liverpool Eye and Ear Infirmary on May 7th, 1906, with a history of suppuration in the right ear for two years; temperature 100°, and pulse 126. She had a cough, was emaciated, and looked very ill. After a week in the infirmary patient was discharged, as her condition suggested advanced phthisis. Eight months later the girl returned, being in better health, but still suffering from a profuse discharge and severe pain at times.

As no abnormal signs were now detected in her chest, Heath's operation was performed in January, 1907. When last seen her ear was soundly healed, and she could hear my watch readily at 20' in a somewhat noisy out-patient room, which is excellent hearing. I am inclined to think that the condition supposed to be phthisis was probably an attack of septic pneumonia secondary to the disease in the ear. Skin-grafting was not necessary in either case. I may perhaps here be permitted to mention that I have recently employed Heath's method in two cases for the treatment of acute suppurative disease of the mastoid cells and antrum, and think that the operation will be useful in these cases.

The Radical Mastoid Operation.—This operation is indicated when the disease is of an extensive and destructive nature leading to disorganisation of the mucous membrane lining the tympanum and mastoid antrum, or caries or necrosis in the deeper parts of the bone, and when other methods of treatment have failed. Subsequent skin-grafting by Thiersch's method, although not always necessary, is of the greatest value when the exposed granulating area of bone is extensive, as occurs when the mastoid antrum is large and its lining membrane destroyed, many months of troublesome after-treatment being avoided by its adoption. The grafts may be introduced through the post-aural wound or the enlarged meatus, according to circumstances. In the case of a boy who happened to be a bleeder, I used frog-skin with an excellent result. During the past two years it has fallen to my lot to perform the radical mastoid operation at the Liverpool Eye and Ear Infirmary on sixty occasions. In this consecutive series of operations two marked anatomical variations were met with. In one, the lateral sinus was very superficial and situated immediately behind the posterior wall of the meatus,—the bone in each position being less than ¼-inch in thickness, and the bony meatus small. In this case the difficulty in obtaining sufficient room to use even a small gouge was so great that I performed the whole operation with a small burr, driven by an electric motor. In the other, the mastoid antrum was absent, but below the Fallopian canal there was a deep recess, which has been termed by Mr. Ballance the fossa of the aqueduct. Attention was drawn to the importance of this fossa in a paper on the "Surgical Anatomy of the Temporal Bone," read at a meeting of this Society a few years ago by my friend and colleague Mr. Hugh E. Jones. On this patient I performed my thirty-seventh radical operation; and being unable to find the antrum in the ordinary way, introduced Stacke's protector into this fossa, thinking it to be the antro-tympanic passage, cut down upon it, and injured the facial nerve. I have since ceased to use this instrument.

Facial Paralysis.—The abnormal condition I have just described occurred in a man æt. 38 years of age. He had suffered from a purulent discharge from the left ear for nine years, with frequent severe attacks of pain which kept him awake at night. His discharge and pain have been cured and his hearing improved, but he has facial paralysis as a result of the operation. However, the fact that chronic suppurative disease of the middle ear often leads to paralysis of the facial nerve must not be overlooked, since in five patients it was present from this cause when they first applied for treatment, and one developed it as a result of the disease while under treatment. Of these six patients in whom the nerve was involved by the disease, one had recovered completely three months after the operation, and a recent case is steadily improving.

Two cases, when last seen, were *in statu quo* in one the greater part of the cochlea was removed as a sequestrum. The fifth case I mention occurred in a baby eight months old. It was first seen in November, 1906, and had suffered from a discharge from the left ear for seven months; this was profuse and very offensive.

Exploration revealed the fact that almost the whole of the mastoid and petrous portions of the temporal bone were necrosed. Removal of the dead bone brought into view an extensive surface of dura mater covered by unhealthy granulation tissue both in the middle and posterior fossæ. A considerable portion of the lateral sinus was exposed, and the internal carotid artery could be seen as it descended to enter the cranial cavity. I am afraid the prognosis here is not favourable as regards the nerve. In the sixth case the operation was only undertaken a week ago, so that it is too early to expect recovery.

In considering the risk of life from direct extension of the disease, I find that in five cases the lateral sinus was already laid bare, and septic phlebitis might have originated at any moment. For infection of the sinus to occur, however, it is not necessary that it should be directly bathed in pus, as septic organisms may extend to it along small veins in the bone. In another case the roof of the antrum was perforated, the aperture leading to a small extra-dural abscess in the middle fossa.

THE EFFECTS OF THE DISEASE AND OF THE RADICAL MASTOID OPERATION UPON THE HEARING.

In a large proportion of cases, chronic middle ear suppuration leads to a considerable degree of deafness. Two patients in this series were deaf and dumb as the result. I have previously mentioned the fact that the loss of the drum membrane, with the malleus and incus, does not necessarily cause deafness. On the other hand, removal of these may lead to a marked improvement in the hearing. My observations of the effect of the radical mastoid operation upon the hearing have been most encouraging. In a large majority the hearing has been improved by the operation, and in many cases to a marked extent. In only one case do I find a note that it was made worse, the extent being slight—a diminution of ½' as tested by my watch. Discharge thirty-eight years.

Does the operation lead to a complete and permanent arrest of the discharge; and if it fails in this respect, where is the seat of suppuration? I will admit that discharge may be met with after the radical operation, and proceed to enumerate the causes I have met with:—

(1) Faulty operation or faulty after-treatment; (2) Inflammatory exudation from the Eustachian tube; (3) Omission to skin-graft when the raw area is extensive; (4) Ulceration of weak cicatricial tissue.

Since the above can be prevented or treated, the final result should be a complete arrest of the discharge.

When the radical operation has been successfully performed and the after-treatment efficiently carried out, the patient derives the following advantages:—

(1) Freedom from the ever-present risk of dangerous complications, such as meningitis, pyæmia, or brain abscess; (2) Arrest of a troublesome and often offensive discharge; (3) Freedom from attacks of pain (which are common); (4) Freedom from the risk of involvement of the facial nerve; (5) and lastly, my investigations show usually a considerable improvement in the hearing; and where this does not ensue, I hope its further destruction is prevented. I am inclined to think that when suppurative inflammation of the middle ear has resisted conservative treatment, the risk in every respect of allowing the disease to run its course is much greater than the risk of even the complete post-aural or radical operation; and, further, that if all cases of suppurative otitis media were carefully treated from the onset, the number of cases requiring this operation would be considerably diminished.

ON PHYSIOLOGICAL SINS AND A HEALTH CONSCIENCE (a)

By J. C. McWALTER, M.A., M.D., D.P.H.,
Barrister-at-Law.

By a physiological sin we understand a breach of the laws of health, and by a "health conscience," we mean a habit of thought which induces us to obey the dictates of right reason on matters which concern the health of the community. The stern and awful voice of duty has hitherto only been listened to in the moral domain, and has been supposed to have no jurisdiction in purely physiological phenomena, but we now begin to see the imperative necessity of recognising the teachings of science as they point the means of elevating the physical well-being of a whole people. Because deflections from the laws of health invariably bring their own punishment there has been rather a tendency to sympathise with the offender as one from whom payment to the full would be exacted —as an unfortunate fleeing from a Nemesis sure to overtake him—as a debtor pursued by a merciless creditor certain to exact punishment. The opinion prevailing is that such a one has done what is foolish, rather than what is wrong, and is imprudent, but by no means evil. It now becomes necessary to make it realised that a physiological sin—an infraction of the law of health is not merely the unwisdom of the individual, but an outrage on the community—not simply a matter of individual interest, but an offence against the general well-being. As such it is an offence against society—an anti-social act—and must be punished either by municipal law or by the censure of every right-thinking person. It is obviously an important element in the training of the young that they should be taught to recognise not only what is morally, but what is physiologically wrong, and that they should be encouraged to develop a health conscience to warn them against offences in sanitary matters as well as an ethical sense.

Idleness may be an ethical sin, but it is a physiological sin to work when fatigued. Mental work uses up the energy of the nerve cells, and fatigue follows. "Fatigue in every shape," says Ribot, "is fatal to memory." The impressions received under such conditions are not fixed, and the reproduction of them is often impossible. When an organ is over-active, its nutrition suffers, and halts, and fatigue ensues. When the normal condition is restored memory comes back. Over two thousand years ago Plato taught that in mental matters the half might be greater than the whole. We now find that in elementary schools "half-timers" progress quite as much as those who attend full time. Chadwick insists that children from eight to ten should work only about three hours daily, and those from twelve to fifteen six hours. I submit that to make a child of twelve or fourteen years *submit* to six hours mental study daily is a physiological sin. It is far too much. Fatigue, as Beech points out, rapidly passes into exhaustion. There is soon loss of force, both physical and mental, and action is less easily excited through the senses. Irregular movements will occur, the fingers will twitch when the scholar holds the pen, and he becomes not only fidgety, but nervous and peevish. His eyebrows are corrugated and he is puffed under the eyes. He is slow in his movements, and in his physical activity. His face lengthens through relaxation of the muscles, sighing and yawning set in, his speech is slow and his voice weak. Plainly, it is a physiological sin to let such an individual work at his lessons. He must have fresh air, and sunlight and rest.

Scrofulous children, and those of consumptive parents are often apt to learn; they are quick, sharp, and clever. But it is a sin, in our sense of the word, to do so—they *must* be pushed back, not forced on. We are sometimes told by a medical pedant that there is no such thing as the "brain fever" which novelists and mothers speak of. This is mere playing with words, such children get meningitis and die of it, and the common prejudice which used to exist against forcing precocious children is only too well founded. Hundreds still die every year from premature mental strain. To deprive growing boys and girls of sufficient sleep is another physiological sin. It is greatly doubtful if a boy or girl can sleep too much; it is positively certain that thousands of unfortunate young people have died the victims of the "early to rise" proverb. Dr. Duke says that a boy of ten should get eleven hours daily sleep, and a boy or girl of thirteen years, ten hours. This rule I submit should be amended by adding that if they want more they should have it.

Again, it is a physiological sin to build a school, or to inhabit one, on a clay soil. It is wholly dangerous to children of a rheumatic, gouty, or consumptive tendency. A gravel soil should be selected when possible. I am wickedly tempted to think that it would be a good thing if a boy who for years has spent his days with mouth open, and his nights snoring, and who has been the victim of chronic headache and the butt of everybody for his stupidity, were to shoot his parents when he grows up and finds himself deaf and useless, and hears that he could have been cured if his mother had troubled to bring him to a surgeon to get his adenoids removed in time. Ideas of parental duty are being rapidly recast and fathers and mothers who are now inclined to deride us as faddists because we insist on medical inspection of schools and scholars will shortly be called on to render a terrible account to their offspring if they find themselves the victims of defects of vision, or hearing or health, or of deformity, which the parents could have had corrected if they had listened to our warning in time. Nothing is more certain than that in a few years children will demand satisfaction from their fathers for every evil or inconvenience from which they suffer, and which might have been averted by timely care.

Fifty years ago Herbert Spencer spoke with wonder chastened with admiration of a friend of his, a physiologist, who declared that his children should be taught nothing until they were eight years of age. We have during the half century tortured and killed hundreds of thousands of children by sending them to school at three and four and five years, and yet we insist on a still larger holocaust of victims before we will be convinced of the folly of our acts. Still, we have learned something from those hundred of thousands of victims, and it is now scarcely necessary to argue that it is a physiological sin to send a child of three or four, or five years to school; seven years ought to be the lowest limit, and up to that age the whole energy of the parents ought to be expended in making the child a healthy little animal. If it is ill-behaved all the better. It is simply wicked to punish the natural instincts of young children in order to make them behave.

It is a physiological sin to make boys and girls keep quiet unduly much. As motion is the only means of practising anything, it ought to be encouraged.

(a) Paper read before the International Congress of School Hygiene at London, August, 1907.

Motive action should be cultured and directed to definite ends. As children grow older ideal suggestions have more force so that the memory image of a movement is apt to produce the movement itself. Fletcher Beach shows that children can control the muscles of the limbs before those of the fingers, and it is cruelty to force a child to write before it attains control of the limb muscles. There is now less need than formerly to insist on the physiological wickedness of long hours of study; the mind like the body, can only assimilate at a certain rate, and if you drug it with facts faster than it can assimilate them they are soon rejected. Much of the honour for bringing about a clearer vision as to the folly of the older system of protracted study is due to Herbert Spencer, who so eloquently exposed the fallacy where he says:—

"Once more, the system is a mistake, as involving a false estimate of welfare in life. Even supposing it were a means to worldly success, instead of a means to worldly failure, yet, in the entailed ill-health, it would inflict a more than equivalent curse. What boots it to have attained wealth, if the wealth is accompanied by ceaseless ailments? What is the worth of distinction, if it has brought hypochondria with it? Surely no one needs telling that a good digestion, a bounding pulse, and high spirits, are elements of happiness which no external advantages can out-balance. Chronic bodily disorder casts a gloom over the brightest prospects, while the vivacity of strong health gilds even misfortune. We contend, then, that this over-education is vicious in every way—vicious, as giving knowledge that will soon be forgotten; vicious, as producing a disgust for knowledge; vicious, as neglecting that organisation of knowledge which is more important than its acquisition; vicious, as weakening or destroying that energy without which a trained intellect is useless; vicious, as entailing that ill-health for which even success would not compensate, and which make failure doubly bitter."

In avoiding one physiological sin we fall into another. So soon as it had been drilled into the dull head of the British parent that an excess of mental work was a mistake, that there was much to be said in favour of play—that all natural instincts, and all pleasure-giving instincts subserve a useful purpose—he proceeded with the zeal of a proselyte to go in for games in the schools, but instead of letting the lads have wholesome play he exorcised the greater part of its joy and benefit by converting exercise into a formal and rigid system of gymnastics. Happiness is the most powerful of tonics, and though in a measure gymnastics are good, and far better than study, for children, they lack that spontaneity and agreeable excitement which gives so much value to play. The riotous glee of children at their games cannot be re-placed by carefully graded gymnastics.

The feeling that girls should not indulge their sportive instincts as freely as boys is gradually dying out, but many prejudices against it still prevail. Nothing is so baseless as the view that games indulged in by the natural instinct of girls, and not forced upon them, tend to give rise to unladylike habits. On the contrary, experience proves that they lead to a more harmonious development of the female organism, and that the finest female characteristics follow the development. As Spencer finely says, whoever forbids girls the sportive exercises prompted by Nature forbids them the divinely-appointed means to physical development. One might go farther, and proclaim that it is a physiological sin to forbid a child anything which it wants to eat or drink. Instinct is a perfect guide in the lower animals—it is unerring in infants—it is always useful in invalids; it is seldom unsafe in adults leading an ordinary life, and why should we deem it bad for growing boys and girls? Our forefathers had a rough general rule that natural instincts were the results of some inherited vicious trait and ought to be checked or denied or extirpated. It was an article of faith that sugar was bad for children, that they should behave and keep quiet, and that the wisest man was he who kept children under the most severe control. Now we know that the desire of young people for sugar is most useful for their nutriment, that it is a blunder to obliterate natural instincts, and that excessive control is most injurious in its after effects, but we hesitate to proclaim the great truth of which these are particular instances—namely, that all the desires of children are good, and that none of them should be stamped out, but merely subjected to some control.

We are told on authority that the effects of casual repletion are less prejudicial, and more easily corrected than those of inanition, and that excess is the vice of adults rather than of the young, who are seldom epicures. The passion for meddlesome mis-government finds an outlet in the nursery when it can be effectually resisted elsewhere.

The laws of health must be recognised before they can be conformed to, and hence the imparting of a knowledge of the laws of health is a necessity for a more rational method of teaching and living. Full robust health is the surest pledge of happiness, and none can hope to enjoy it who have not some inkling of its rules. These have not been taught hitherto in the schools, those who have learnt them have picked up their information in various by-ways and corners apart from the orthodox sources. The time has come for the creation of a national health conscience for the universal recognition of the duty of every man not to injure his neighbour in health no more than in purse. If the functions of a health conscience were recognised we should not have one person insisting that the window of the tram or train be closed, lest he should get cold, whilst half a score of others are suffocated or diseased for want of fresh air. The Public Health Acts make it penal for persons who suffer from scarlatina or the like, to travel on public vehicles, but those who have influenza or consumption may be much more dangerous and these travel at will. Many travellers complain that the American laws against expectoration amount to a perfect tyranny, but unless the health conscience of our people protects them against indulging in this disgusting vice for the future, we must have as drastic laws for this country. Another plague which would be exterminated if the health conscience existed is that of ringworm and the allied skin diseases which are the bane of every school. Let a mother's children get ringworm or whooping cough, or measles, or any ailment reputed "catching," and she is perfectly indifferent if every other child in the town gets the same—in fact, she not only invariably blames the school, but she feels rather a grievance if the other school children escape the maladies. She will further exhibit the utmost ingenuity either to keep her affected children at school, or at least to send them back before they cease to be sources of danger to others. That a grave obligation exists in every family and on every individual not to propagate to others the disease from which they suffer is a truth which must be instilled into the mind whilst it is still young and impressionable. And finally, as there are physiological sins against individuals, those also commit a physiological sin against the State who fail to rear a healthy stalwart race to succeed them. To bring to the country's service a large and healthy family is not only to discharge our duties to posterity, but is a proof of clean living, and high thinking and fine ideals. Year after year the Registrar-General's returns bring irrefutable evidence of an almost widespread desire for this obligation to be shirked, and morally it is a pressing duty on every educational system to instruct each rising generation on the nobility of paying this debt.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

Cholecystectomy.—Mr. Joseph Cunning operated on a woman, æt. 56, who had been admitted with the following history: For twenty years she had suffered from attacks of pain in the region of the gall bladder. Two of these attacks of pain many years ago were evidently typical biliary colic, but the later attacks of pain were of a different nature; that is to say she had attacks of pain, vomiting, and constipation, lasting for several days, which were evidently attacks of localised peritonitis. The last attack had laid her up for three weeks. Another point in the history was that she had never been jaundiced. Her symptoms since admission consisted only of tenderness on pressure in the neighbourhood of the gall bladder. Mr. Cunning, before operation, pointed out that the patient's present condition, together with her previous history was sufficient to diagnose the presence of a gallstone, without any history of attacks of biliary colic or of jaundice, for, if there was one large stone, there was no possibility of its getting into the cystic duct, and thus producing colic, or of its blocking the common duct and thus giving rise to jaundice; everyone nowadays admits, he said, that gall stones are a result of a catarrhal infective inflammation of the mucous membrane of the gall bladder, the presence of a stone in the gall bladder having pathologically the same effect as a concretion in the appendix, that is to say, the stone produces ulceration of the mucous membrane, so allowing bacterial invasion of the walls of the gall bladder and attacks of localised peritonitis, which may be either adhesive or suppurative, just as is the case when there is a concretion in the appendix. Further, even if there are multiple stones in the gall bladder and the cystic duct is narrowed or obliterated, there need be neither colic or jaundice; but if there had been definite attacks of pain and rigidity in the neighbourhood of the gall bladder associated with vomiting and constipation clearly indicating localised peritonitis, the surgeon was bound to recognise the presence of gall stones. The abdomen was opened through the right rectus by an incision six inches in length; the gall bladder was at once seen to be densely adherent to the liver, omentum and transverse colon. Packing was put in to protect the rest of the abdominal cavity, and the adhesions were with difficulty separated. During this process a fistulous communication between the fundus of the gall bladder and the transverse colon was exposed, and separated from the gut by excising a portion of the intestinal wall and stitching up the opening. Deeper down between the gall bladder and the duodenum the cheesy remains of an old abscess cavity were discovered. The peritoneum on the sides of the gall bladder was now incised and reflected so that with the finger the gall bladder could be stripped from the liver. The cystic duct was next isolated, clamped in two places and divided, and the gall bladder now being free was removed; the stump of the cystic duct was then ligatured. A drainage tube was then passed down to the site of the duct in case any leakage should occur and gauze was packed round it. The abdominal wall was stitched up in three layers, leaving just sufficient room for the tube and the gauze to project at the upper end. Mr. Cunning remarked that it might have been seen that a pillow was placed under the lower part of the thorax before the commencement of the operation to throw the upper part of the abdomen forward; he considered this an important point in the technique of gall bladder surgery, for it brings the parts concerned in the operation so much better into view. Another point in the technique of the operation, he said, was not demonstrable in this case, that is rotation of the liver: if the right lobe of the liver is grasped and pulled up through the wound, so as to rotate the liver on its attachments, the gall bladder and the cystic ducts are brought prominently into view; in this case there were so many adhesions about the right lobe that rotation was impossible. He preferred cholecystectomy to drainage of the gall bladder as the operation of choice when there was no blockage of the common duct, for it removes a diseased structure, and so prevents the possibility of the further formation of stones and the possibility of a fistula remaining after drainage. Again, it was not safe to drain a shrunken gall bladder, owing to the difficulty of bringing it near the external wound. The circumstances, he thought, under which the surgeon would prefer drainage to cholecystectomy were: if he had unskilled assistants, or if the patient were very fat; here the depth of the wound is so great that it is safer to drain rather than to excise the gall bladder. On opening the gall bladder which had been removed from the patient just operated upon, its walls were seen to be a quarter of an inch thick, the cystic duct was obliterated and there was one large single stone which was facetted. The explanation of the facetting and the singleness of the stone was accounted for by the presence of the fistulous communication between the gall bladder and the colon clearly showing that one or more gall-stones had escaped by that route; the one found in the gall bladder being about the size of a walnut had evidently been unable to escape into the colon. A little bile leaked from the wound during the first two days; this probably came from the raw surface of the liver, from which the gall bladder had been detached. Ten days after the operation the wound was soundly healed, and the patient going on well.

TRANSACTIONS OF SOCIETIES.

NEW SYDENHAM SOCIETY.

FORTY-EIGHTH GENERAL MEETING, HELD IN EXETER ON THURSDAY, AUGUST 1ST, 1907.

Dr. OSLER in the Chair.

THE report and balance-sheet for 1906 were presented. The report concluded with a recommendation from the Council that the Society should not be continued beyond the end of the current year.

In response to a request from the CHAIRMAN, Mr. HUTCHINSON said that, though he had himself written the report adopted by the Council, he was not wholly in accord with the recommendation that the Society should wind up its affairs. There were still nearly 900 members, and his sympathies went with the proposal that the Society should continue its work with certain modifications. He would propose to publish every year a volume of clinical lectures, short monographs or papers, translated from foreign sources, as promptly as possible after their original issue. The work of abstract-making which the Society's Year-Book used to accomplish was now exceedingly well done in the medical journals, but not a few of the papers with which medical literature now teems were well worthy of reproduction in full, and a valuable and attractive annual volume might be thus constructed. Secondly, he would like to see the Atlas continued, but with plates reduced in size and with less letter-press. It should copy nothing and produce only original illustrations of new subjects. It might suitably treat the subjects comprised in the volume of translated monographs. It might also undertake to reproduce selected drawings from among those exhibited at the annual meeting of the British Medical Association, and for this it might venture to ask for a subsidy. It might also come to an arrangement with the Royal Society of Medicine to publish some of the plates accompanying papers read before the Society, thus giving them a wider circulation and at the same time enriching the Atlas. It might be worth a thought whether a remodelled Society might not become more international in character, and enter into close relations with all English-speaking communities. He much hoped that the Society would not be given up, but that it should be remodelled somewhat on the above lines.

Dr. LEON proposed that a circular be sent round to the members, in which they should be asked whether they were in favour of the recommendation made by the Council that the Society should not be continued beyond the end of the current year, or of carrying on the Society on the lines suggested by Mr. Hutchinson. This was seconded by Fleet-Surgeon **Bassett**, and carried unanimously.

Dr. **Baildon** then urged that, in view of the importance of this step, it would be well that a statement of the outstanding liabilities and of all the assets of the Society should accompany the circular. This was seconded by Dr. **Gibson**, and carried.

Dr. **Coombes** proposed that the statement should be made by a chartered accountant. This was seconded by Dr. **Gibson**, and carried.

Mr. **Power** pointed out that many subscribers were more than satisfied with the atlas, and that some had paid for several years in advance.

Dr. **Russell** drew attention to the fact that the income of the Society had steadily diminished for several years past. There was unfortunately no indication of any recovery, as a large number of resignations had been received this year. At the present moment the Society was solvent, and if no further diminution in its members occurred, it could just be carried on, but with any further shrinkage a deficit would have to be faced, or its output would have to be diminished.

The meeting terminated with the usual vote of thanks.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Sept. 1st, 1907.

Abortion.

It is not always easy to make a correct diagnosis of abortion, certain circumstances, more or less frequent during the first two months, where the existence of pregnancy cannot be affirmed, may present themselves, and the question arises as to whether the case is really one of miscarriage or due to some other cause producing the symptoms observed. The diagnosis becomes thus very difficult, as no certain sign of gestation is observed, nor the usual symptoms generally accompanying the accident.

It is frequently thus with women who menstruate irregularly, or who become pregnant during the period of nursing, and who cannot reckon on the cessation of the menses. Sometimes also, local examination is rendered very difficult by the presence of subcutaneous abdominal adipose tissue.

In abortion the hæmorrhage, say Lepage and Ribemont, generally precedes the uterine contraction; the os presents certain modifications, it is patent, softened, and the clots are abundant. In dysmenorrhœa the pains precede the flux, the os is closed, the uterus is small.

In cases of fibroma complicated with metritis the diagnosis is almost impossible, at least for some time.

The question, has abortion taken place, appears simple enough at first sight, but it is not always easy to solve it, and even frequently impossible.

In the third or fourth month an error is impossible if the fœtus can be obtained; but in the first weeks the ovum is so small that it passes unperceived in a large number of cases. The majority of women believe simply in a more or less turbulent return of the menses which had been retarded. On the other hand it frequently happens that before the doctor has arrived, everything has been thrown away; clots and membranes, or the patient, seized with an imperious need to go to the lavatory, allows the whole mass to escape without paying much attention. The difficulty is still further increased from the fact of the death of the fœtus and its more or less prolonged retention in the uterine cavity.

Even when the physician has the parts under his eyes, it is often difficult to pronounce during the five or six weeks of gestation on account of the small volume of the ovum. The clots and different débris should be carefully examined under a stream of water and, where possible, the microscope should be employed, especially where the question is one appertaining to medical jurisprudence.

It is not always easy either to know if the abortion is complete, for the reason already given, but the general retention of the whole or of a part of the placenta may be inferred where the hæmorrhage persists when the uterus remains voluminous, and a priori when the finger can feel a portion of the placenta in the interior of the uterus.

The four great causes of abortion are:—Criminal manœuvres, syphilis, albuminuria, and vicious insertion of the placenta. Criminal abortion is difficult to determine and as admission is not easily obtained it can be only suspected. When it is of syphilitic origin the fœtus is expelled dead and macerated. If albuminuria is the cause the placenta presents hæmorrhagic spots and the urine contains albumen, there are signs of nephritis. In case of vicious insertion of the placenta recurrent hæmorrhage is observed, and the examination of the membranes will reveal the insertion on the inferior segment. The prophylatic treatment of threatened abortion needs no comment: rest in bed, opium by the mouth or by the rectum, viburnum prunis folium, ten drops of the tincture five times a day.

Where the miscarriage is unavoidable, where the hæmorrhage persists, the contractions continue, or the membranes are broken, or the fœtus is dead, the case should be treated as an ordinary confinement—disinfection of the external organs, antiseptic injections, and an antiseptic compress over the vulva and events awaited. Several complications are adherent to cases of miscarriages.

At first the hæmorrhage may be so intense that the life of the patient is threatened. If the ovum is intact and uterus closed the vagina may be plugged with antiseptic gauze for eight or ten hours. This plug excites by its presence the uterine contractions, and it is not rare to find behind it, when withdrawn, the ovum or the fœtus, the placenta being retained.

The ovum may be infected, although it may be intact, and here the plug can be used in provoking contraction. But if no result is obtained at the end of some hours, the patient should be chloroformed, the vagina disinfected, the os gently dilated and the uterus evacuated by digital curettage and abdominal expression.

Abundant and repeated hæmorrhage after expulsion of the fœtus may be also treated by the plug, but it is frequently badly done and inefficacious, allowing the hæmorrhage to continue behind it, retaining the clots and favouring infection.

To obviate this inconvenience, Auvard recommends intra-uterine plugging, which can render service in cases of extreme urgence, or where the patient is so weak that she is unable to support a curettage. Otherwise this method should be rejected as it might be the cause of accidents; digital curettage is much preferable, it suppresses the hæmorrhage by emptying the uterus and affords complete security.

Where the placenta is partially detached, or has fallen into the vagina, one is tempted to extract it either with the fingers or with a forceps, pulling at it with the hope of taking it out. Such a practice is reprehensible unless the operation is fully completed. Otherwise the placenta is broken and the hæmorrhage continues to endanger the life of the patient.

Frequently the placenta is retained after the fœtus is expelled with no other complications, neither hæmorrhage nor infection. Under such circumstances, expectancy is the rule. In the majority of cases, at the end of some hours the contractions recommence and the placenta is expelled.

The limits of this expectancy are difficult to determine; the placenta can remain several weeks in the uterus without provoking any infection and is finally expelled. In any case if it is decided to await events, the patient must be subjected to constant surveillance, the temperature taken morning and evening, vaginal antiseptic injections ordered, and everything held in readiness for artificial delivery in case of infection.

Even in cases where there is neither fever nor hæmorrhage prudence commands that the placenta should not be left in the uterus more than four or five days. The two methods employed for extracting the organ are instrumental and digital curettage. Each of them has its partisans and adversaries. Some prefer the curette during the first two months because the uterus is not much developed, the walls are sufficiently resisting, that there is no danger of perforation, that it is easier to penetrate the uterus without dilating the os, and that properly handled the instrument is cleaner and more easily disinfected than the finger.

Others reproach the curette with working in the dark, that it runs the risk of perforating the uterus, that it does not inform the operator on the complete and perfect cleaning out of the cavity in which débris of the placenta might be left.

The majority of surgeons of to-day reject the curette, among whom may be cited Pinard, Budin, Lepage. Every time that digital curettage is possible it should have the preference. If, as is customary with some surgeons, the curettage is done an hour, or two after the expulsion of the fœtus, no previous dilatation with Hegar's instruments is necessary. One or two fingers are passed into the uterus and the placenta extracted

Antiseptic irrigation follows to remove any small pieces, and finally the uterus is swabbed out with tincture of iodine or glycerine and creasote (1–5). After another antiseptic injection of the vagina a plug of iodoform gauze is passed into the uterus to ensure drainage. This plug is removed after twelve hours, and the intra-uterine injections repeated.

GERMANY.

Berlin. Sept. 1st, 1907.

AT the Hofeland Society, Hr. Westenhoeffer gave an address on

THE PRACTICAL SIGNIFICANCE OF THE THROAT AFFECTION IN CEREBRO-SPINAL MENINGITIS.

He said it was now generally recognised that in cerebro-spinal meningitis the tonsillar affection was the primary one. It was maintained by Hr. Goeppert, Kattowitz, that the whole respiratory tract was the point of entrance for the meningitis. This disease might easily escape observation, as the inflammation was seated in the upper part, hidden by the velum palati and was not on the tonsils. The cause of the primary localization lay in the lymphatic apparatus. The majority of the children attacked were such lymphatic characters. From this the rule should be drawn that the throat should be examined in all suspicious cases. Cases of meningitis were originated from the nasal passages, but not by the meningococcus. but by pneumococci and streptococci. On the other hand tuberculous meningitis did not set up a similar disease in the nares.

The attempt had been made to eliminate the disease from these parts by means of all kinds of gargles and washes for the nose and fauces, but without success. Meningococci seated in the mucous membranes were very resistant. Even removal of the tonsils had not been followed by any good results. Attention had very properly been drawn to the fact that a large bleeding wound only made more room for the bacteria to enter.

It was remarkable that the throat affection disappeared very quickly. It was present in the first days of the disease only and then showed intense redness and œdematous swelling.

The throat affection was, however, the cause of the extension of the disease. The germs must enter with the air respired and settle on the first suitable spot. The further spread occurred through expectorant material. As, however, children did not expectorate the schools were never the carriers of the infection. Although epidemic meningitis was exceptionally a children's epidemic, 90 per cent. of those who suffered from the disease being children, the spread took place through adults affected with the disease who expectorated the disease germs. All the people of industrial or colliery districts had a tendency to spit more than others, the possibility of the spread of the disease was, therefore, so much the greater amongst them.

There might be cases in which there was no throat affection. What, from a sanitary point of view, should be our attitude in respect of such cases, as such patients did not expectorate? The speaker related the case of a young man who had had his lumbar spine cocainized on account of an operation for piles who in some unexplained way developed cerebro-spinal meningitis. The throat was intact.

The epidemiological significance of the naso-pharyngeal affection lay in the fact that in all the cases the meningococcus could be found in the naso-pharyngeal space and the disease carriers determined. The infection passed along the nerve tracts, especially that of the trigeminus, and from here deep into the muscles of the pharynx. The disease gradually lost itself towards the periphery. Suppuration very rapidly attacked the muscles of the eye and the ciliary ganglion. As a rule, at least, there was no homogeneous infection of the brain. Before anything was seen in the meninges suppuration was seen round the arteries. The epidemics differed fundamentally; exactly as the clinical course might be, the anatomico-pathological appearances might differ just as much.

In the face of this disease treatment was powerless. Lumbar puncture was useful in some cases in others not. It only mitigated the symptoms. The same applied to other methods of treatment but in a higher degree. There were cases in which recovery took place during the first week. The cases are then as well as before, but a great number died during the first week and of the general intoxication. The remaining group was divided into those that recovered but with grave lesions of the nervous organs, especially those of sense, and those that died later. For these varied courses varied methods of treatment must be adopted.

Meningococcus serum had been recommended in the acute stage. Some favoured, others rejected it. The views were also most varied as to whether it should be used subcutaneously, or by the rectum, or spinal canal. Injections into the canal of the cord were the most deserving of confidence. The mortality, independent of treatment, was varied. In the Upper Silesian epidemic the mortality was from 50 to 70 per cent., in that then on it was 44 per cent. The injection of serum certainly did no harm.

When the disease had advanced into the second stage that of pyocephalus surgery was more in place than the injection of serum.

The speaker then showed how by trepanning at two spots the suppuration at the descending cornu could be drained. He had suggested methods of performing the operation and it had already been put into practise with success.

AUSTRIA.

Vienna, Sept. 1st, 1907.

LIPOID BACTERICIDE.

LANDSTEINER and Ehrlich have now completed their experiments with fatty material and give the following report: "We have carefully examined fatty hæmolytic substance in the form of organic extracts and found in every one of the experiments a positive result as a bactericide. We have found the extracts powerful toxines, for bacillus anthracis, vulgaris Bayeri, etc., as well as the fatty acids obtained from these extracts in the form of an emulsion. If this fatty acid be presented along with serum and then warmed it becomes inactive as bacterio—or hæmolytic—serum, but if this fatty acid is prepared in an aqueous solution and warmed in the same manner the bactericidal property is still retained and the results positive.

In the same manner we examined tissues with virulent Milzbrand bacilli after having treated them with the lipoid extracts and found them powerfully resisting the bacilli and therefore protective.

These experiments were carried on in the blood of animals with the same results in the leucocytes and medullary substance of bones.

We have also observed that Towel's bone marrow in a physiological solution of salt with the serum of the animal has a decided bactericidal action. This effect also disappears on gently warming the æther and serum mixture, but is retained if the component fluids be warmed separately.

They conclude with an assumption that bactericidal properties of the marrow of bones will yet play an active part in the treatment of germ disease or the intracellular bacteriolysis of the body.

Congenital Cerebral Motor Defects.

At the present time we have a large number of dreamers. The motor power of the brain only requires to be aroused to impart activity to the human organism, but very few apply themselves to investigating the real cause of this defect before commencing this resuscitating stimulant. We hear of many being born tired and unfit to continue the struggle for existence. Some attribute this primary agenesia to a congenital inhibition of the central ganglia of the brain, like Heubner, Delille, etc., while Möbius is inclined to accuse the nerve trunks which are often damaged by toxic agents that produce an enfeeblement of the nerve centres with consequent dystasia and agenesia of the muscular system. Neurath, in his anatomical research on the subject, has now concluded that both theories may be correct, and probably the one is the complement of the other. The loss of function may be developed in the trunk as well as the centre and both may be the result of a toxine. Neurath thinks that many of the cases the dystasia is in the muscular system itself, making a third source of production in the developmental inhibition. He is in doubt, however, whether the defect is in the centre, trunk or muscular apparatus.

Hereditary Squint.

Licherer records an interesting case of squint with ocular disturbance, handed down through several generations. The family seems to have been affected with strabismus during at least four generations; the first and second having large families, in whom the males, nine in number, had all strabismus convergens in the left eye. Strange to say, the children of those affected had also strabismus convergens in the left side with the additional ocular disturbance of hyperopia and amblyopia, while all the females were emmetropic and had no squint. The boys throughout these families confirmed Douder's assertion that strabismus convergens is somewhat closely associated with hyperopia and reduction of acuity of vision. The eldest son of the first family had three children, of whom the female was emmetropic, while the boys were emmetropic in the right and hyperopic in the left.

Cerebral Fatty Embolus with Tetanus.

The patient was healthy, but after a slight injury died. The clinical observation convinced Schmidt that the symptoms were the result of a fatty embolus. These signs were great disturbance in the circulation, with other changes in the motor phenomena that were inexplicable from tetanus alone. This was proved by many of the symptoms being relieved by removing the compression and providing collateral circulation, which improved the mental condition of the patient. The wound and its secretions were carefully examined for tetanus bacilli, but all in vain, though animal vaccination gave positive results. He concluded that the tetanus bacilli played a very small part in the toxic condition of the patient.

HUNGARY.

Budapest, Sept. 1st, 1907.

Gross Negligence of Two Forensic Doctors.

In Szeged, a large country town in Hungary (seven months ago), a railway servant took a girl to a hotel, where she, after enjoying herself fairly well with the servant, suddenly died. The girl was carried to the morgue, where two forensic doctors performed the *post-mortem* examination. Seeing a stabbed wound under the left eyelid of the corpse, they stated that the girl—who, by the way, was pregnant, being about in the eighth month—was killed; likely a pleasure-murder had been committed on her. On account of this statement of the doctors the servant was sentenced to seven years' imprisonment.

About two weeks ago the case was brought before the highest Court of Justice, the so-called Royal Curia, where the documents were given to Dr. Minich, member of the Board of Justicial Medical Advisors. He read the report of the two Szegedian forensic doctors, and spoke of the seriousness of such a fatal error as had been committed by them. He argued that "the man, who had been found guilty of committing murder, was innocent, because the cause of death could not have been the alleged stabbing wound under the eye. We know that even enucleation of the eye bulb does not give rise to such fatal bleedings as to cause death. (The forensic doctors alleged that the arteries of the bulb got retracted in the skull, and caused a hæmorrhage there, resulting in the death of the girl.) On the contrary, the apertures through which the arteries leave the skull, are so tight that the vessels cannot get retracted there. Besides, they are not such large vessels that a patient could die on account of their bleeding. We know that pregnant women, especially those nearing to the end of gestation, may get apoplexy in consequence of the bursting of a cerebral or meningeal vessel."

According to this opinion of Dr. Minich the Court ordered the exhumation of the corpse; this was done on the 17th of this month. The *post-mortem* examination has been performed by Dr. Genersich, professor of pathologcal anatomy. He found the bony eye hole intact, so that an injury of the brain at the time of the alleged stabbing could be excluded. He opined that death had been due to an apoplexy. As for the injury under the left eye, he expressed his suspicion that it must have been done after the death of the girl. This supposition was now born out by the confession of two witnesses, who carried the corpse from the hotel to the morgue. The men alleged that they had not seen any injured spot on the cadaver when they transported it from the hotel to the Morgue.

Dr. Genersich thinks that the wound arose either from rat-bite or was made by the throwing of the body hither and thither during transport.

The innocent railway servant was set free immediately after the declaration of Professor Genersich.

French Doctors in Budapest.

Twenty-six French doctors, all members of the Œuvre d'enseignement médical complémentaire, came on the 16th of August to visit Budapest and its medical institutions. Although the clinics were closed — being vacation — several notable professors left their summer residence and came back to Budapest to receive the guests in their own clinic. Lectures were held on different subjects, especially on surgical matters, and dinners and banquets were given in abundance during the three days stay of the illustrious guests.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

BELFAST.

Death of Dr. Henry Murney, J.P.—One of the oldest, if not the oldest, member of the medical profession in Ulster passed away last week in the person of Dr. Henry Murney, who had attained the good old age of 83. His death was rendered rather pathetic by the fact that his sister, five years older than himself, who lived with him, and to whom he was deeply attached, died only a few hours before him. It was no doubt partly owing to this shock of her death that the end came suddenly to him. Dr. Murney was born in Belfast in 1824, and entered practice in 1849. In 1854 he was elected to the staff of the General Hospital, now the Royal Victoria Hospital, and for many years was an active member of it, and honorary secretary to it. He joined the Ulster Medical Society in 1847, and was president in 1871. He retired from active practice about 1884, and went to live at Holywood in Co. Down, where he lived the remainder of his life. Dr. Murney was a broad-minded Catholic Liberal, and a favourite with all classes and creeds. At one time he was a prominent member of the Masonic body, and a Justice of Peace for both town and county.

LETTERS TO THE EDITOR.

MILK AND TUBERCULOSIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is quite evident that "A Family Doctor" regards bacteriological experiment in the laboratory as of more value than clinical observation.

I do deny that it has been demonstrated that tuberculosis has ever been communicated to the human subject by means of the tubercle *bacillus* conveyed in milk. I again ask for a single case.

"A Family Doctor" says, "the *possible* sources of infection in the case of the cow have been demonstrated by Dr. Armstrong." But I ask for the *actual* sources; for it passes my limited comprehension how a possible source of infection can be demonstrated. If it be demonstrated it is no longer a *possible* but an *actual* source. To say that a thing is possible cannot lead to any conclusion.

I repeat that "A Family Doctor" accepts statements unsupported by *evidence*.

It is only within a few years that the doctrine of the infectivity of phthisis has taken hold of the professional mind. Yet when this question was investigated at the Brompton Hospital for consumption not a single case could be discovered in which a servant or nurse had become infected.

The improvement that has taken place in the incidence of this disease throughout the country has been independent of the application of so-called modern science towards its ousting.

I have already shown that the *want* of milk plays a far more important part in the production of this disease in the young than so-called infected milk.

As it appears to be a hopeless task to wean "A Family Doctor" from his views in favour of bacteriological experiment as against clinical observation I shall not trouble you further.

I am, Sir, yours truly,
August 31st, 1907. GEO. GRANVILLE BANTOCK.

SANITARY ADMINISTRATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The *Times*, of August 26th, publishes a summary of Local Government Board Reports on the sanitary condition of numerous Lancashire boroughs and urban districts. The reports form a terrible indictment of the various authorities. In every district, Acts of Parliament, upon which the health of the people depend, and which it is the duty of the authority faithfully to administer are neglected or even completely ignored. In most places medical officers and sanitary inspectors are either not appointed, or are engaged and paid to give only a small and insufficient part of their time to their duties. Councils are often wilfully negligent, or, lacking the advice of skilled and experienced officers, remain ignorant of the requirements of modern sanitation, and unenlightened as to the nature and importance of the trust which the Legislature has placed in their hands. In many instances members of the authority seem evidently bent upon preventing the administration of laws in conflict with their private interests. The state of local government in the areas now reported on closely resembles that in other parts of the country which you have allowed me on previous occasions to criticise. In most of such places public opinion does not exist; recommendations of the Local Government Board, such as are made in the present reports, are disregarded, and vast masses of the people throughout the land are thus allowed to exist under conditions which give rise to great preventable mortality with corresponding injury to the physique of the nation. By far the greater part of the injury falls upon the poor. The impossibility of getting milk of fairly good quality for their infants in the many places where the adulteration Acts are not enforced, forms alone a terrible hardship for poor mothers. It would be easy to paint a picture of misery arising almost solely from bad government sufficient almost to justify the wild and revolutionary demands of the socialists whose fanaticism is very often roused and kept up by contemplation of the undeserved sufferings of the poor, to which society seems so callous and indifferent. The only cure for these evils lies in the rousing of the spirit of the nation. We ought to be all socialists, in the proper sense of the word, nowadays. If all that is respectable and intelligent among every class of the community will not take its proper share in the working of our democratic institutions these will fail and national ruin in the end will result. Certainly the fanatical socialism of the day will not save us, for that presupposes before everything a high level of altruism, to which only the smallest minority of any class of the people have attained. In the meantime, and pending the evolution of a higher level of citizenship, the position of the medical officer of health will remain in too many places as at present—ill-paid, precarious, and in every moral and material sense, unsatisfactory.

I am, Sir, yours truly,
Lancashire. August 28th, 1907. M. O. H.

SOUTHEND AND ITS MEDICAL OFFICER OF HEALTH.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I venture to draw your attention to the recent action of the Southend Council in relation to its Medical Officership of Health. As a health resort, it is clearly a matter of vital importance to the town to preserve its sanitary standards at the highest possible pitch of excellence. Moreover, there are special reasons, owing to the shell-fish industry and the pollution of the foreshore with sewage, why the sanitary supervision of the place should be one of ceaseless vigilance. It seems hardly credible that under such circumstances the local authorities should have resolved to cut down the salary of their medical officership. Yet such has been the case and I understand that the present able holder of the post has very properly refused to accept a reduced and inadequate salary. The incident has a much wider significance than the mere unwisdom of the local Council of a small but hitherto popular watering-place. It presents the type *par excellence* of the penny-wise-pound-foolish policy that has left most of our watering-places hopelessly out of the race against their Continental rivals. Yet many of our British sea-side resorts are of unrivalled beauty—it is the sordidness of the private and municipal accommodation and the lack of first-rate recreations and public organisation that repels.

I am, Sir, yours truly,
London, Sept. 3rd, 1907. DAVID WALSH.

OBITUARY.

DR. JOHN WILLIAMS, OF CARNARVON.

WE regret to announce the death of Dr. John Williams, Carnarvon. The deceased, who was seventy years of age, was a native of Anglesey. He came to Carnarvon as assistant to the late Dr. Watkin Roberts many years ago, and subsequently joined that gentleman as partner, and remained in partnership till Dr. Roberts's death in 1897. Dr. Williams had been in practice for forty-five years. He was appointed medical officer of Carnarvon Goal in 1887, and was also medical officer for several local friendly societies. He became a member of the town council in 1874. In 1883 he was elected mayor, and during his mayoralty the beautiful Carnarvon Park was opened by the late Mr. Assheton-Smith. In politics the deceased gentleman was a moderate Liberal, and was a Churchman. He married Miss Gregson, of Kirkby Stephen, by whom he had three sons.

ANDREW GRAY, M.A., M.D.Edin., D.P.H.Vict.

We regret to announce that on August 30th the death took place at St. Helens, of Dr. Andrew Gray, one of the leading medical practitioners of the town. On August 25th Dr. Gray was cycling along Corporation Street, when another cyclist came up behind, and in passing came in contact with his wheel. Both men were thrown off their machines, and Dr. Gray sustained a fractured skull. The other cyclist, who apparently escaped unhurt, rode off, and has not yet been identified. Deceased was the son of Mr. Gray, of Dalkeith, a member of the Midlothian banking firm, and who acted as chairman for Mr. Gladstone. Dr. Gray, who was 43 years of age, studied at Edinburgh, and went to St. Helens eighteen years ago, having graduated M.B., C.M. in 1888.

SPECIAL ARTICLE.

A KENT PRACTICE SINCE 1690, WITH A LETTER ON "HE-SHE THINGS."

By GEO. H. BROCKLEHURST, B.Sc.

The village of Elham—which gives its name to the verdure-clad valley between Canterbury and Shorncliffe, which latter Wolfe, whom every schoolboy loves, selected for a military camp—was, up to the close of Century XVIII., a town of considerable importance in Kent. Hasted, in his history of the county, states that: "Elham is said to be the largest parish in the eastern part, extending from north to south, through the Nailbourn valley about three and a half miles, and from north-west to south-east five and a half." He further tells us: "The town is healthy and pleasant; the houses in it being mostly modern and well-built of brick and sashed." That the windows could be let up and down by pulleys, shows how up-to-date the town was in 1793; whilst its relative importance may be judged by its contribution to the county rate being £4 7s. 6d.; that of Sittingbourne being eighteen pence less, and that of Ashford only a guinea and sixpence more.

John Somner—named after his uncle, on his father's side, who offered to give a new Market House to the City of Canterbury on condition that the Corporation would make the market a free one—whose brother William was the vicar of the neighbouring parish of Lyminge, died after being in practice at Elham but a few years. A stone at the extreme east-end of the chancel of the Parish Church states: "Here lyes ye body of John Somner, Gent., son of the learned Mr. William Somner, of Canterbury, who dyed June the 7th, 1695, in ye 29 yeare of his age." Which William Somner was the antiquary, author of, amongst other works, "Antiquities of Canterbury," "A Treatise on Gavelkind," and "Roman Ports and Forts in Kent," published in 1693, which is prefaced by a life of Somner by White Kennett, afterwards Bishop of Peterborough, who states that "John practises Chirurgery with good repute," and that his mother became a "mourning Relict" for the second time, having married "Henry Hannington, Vicar of Elham."

The practice had passed into the hands of *William Pettit*, surgeon, by 1700, who died, aged 61, on April 30, 1739. Then into those of one, whose name is not known, though amongst his fees in the year 1747 are the following:—"Cook; bleeding 1s., two histerick draughes 2s., and a nervous tincture 2s." The next entry, lets "the cat out of the bag." "Cook" is not a surname; but the all-important "officer of health" of a well-ordered household. As the three next entries are "Mr.; the cure of his leg 5s., a cooling mixture 2s. 6d., and a rhubarb bolus 1s. 6d., possibly there had been a little over-eating. A good idea of a "bolus" and of the dress of this period may be obtained from H. Taylor's drawing, "A Country Doctor giving a Bolus to a Patient," engraved and published by J. Cary at the corner of Arundel Street and the Strand, Westminster, on March 25th, 1786," where a lady patient looks inquiringly, if not suspiciously, at the bolus—about three times the size of her thumb-nail, she holds between her thumb and index finger; whilst her medical adviser, whose head is well covered with a bewitching wig and a broad-brimmed soft felt hat, bracing up her courage evidently with "Now then, my dear lady, down with it."

When the "Blacksmith" called the doctor in he was given "a Cathartic 1s. and ointment 6d.; on the following day another Cathartic 1s.; two days after, a third Cathartic 1s, and more ointment 6d.," whilst on the fifth day he had "Phisick 1s.," bringing up his bill to a crown. Probably his wife, for the record states, "Wife of Blacksmith" fell ill just before Christmas—which it will be remembered was kept in March at that date—possibly from over-work preparing for that "family gathering," rightly held in such high esteem by those whose love can extend to each and every member. She was well in three days; the items of her account being: A mixture, on the first, 2s. 6d.; a Cathartic, on the next, 1s.; and a Bottle of Drops, on the last, 1s.

Then followed *James Miller Church*, surgeon, of whom little can be said with certainty, beyond that he evidently was a very common-sensed man. One of his favourite prescriptions was, "Keep the clay cottage of which you are the freeholder for life clean," adding, "then there will not be much wrong with you." Probably he was a son of Samuel Church of Sandwich, who died there on November 18th, 1793, aged 83; and of Elizabeth, his wife, who was buried at Elham on August 21st, 1796, aged 85. If so, doubtless his widowed mother passed her latter days under his roof. As there is no other record in the parish registers under this name, probably he removed to Sittingbourne; as there was a surgeon of this name in that town early in Century XIX. During his last years in Elham, he had as partner, who succeeded him, *Charles Rootes*," surgeon, apothecary and man-midwife," who appears to have been the son of a Nonconformist Minister of York, who died on June 8th, 1755. If so, he was fatherless at the age of 14, and had the advantage of the up-hill work of making his own way in the world—the best to bring out the best in a noble lad. He was in practice in the town by 1778, which was probably the year he came to Elham. He was liberal-minded large-hearted, and, as he had studied midwifery, evidently abreast if not in advance of his day, as the following shortened letter, addressed to the Editor of the *Sunday Reformer*—not the only Sunday paper of that day, by any means—shows.

"When apothecaries' apprentices are out of their time, they come to London to attend Anatomical Lectures, but instead of studying the whole of the human structure, together with practical surgery, they immediately turn their attention to that which is by no means proper for boys and young men—I mean midwifery. . . . The present race of males are become so effeminate, as to make it their chief practice . . . and write 'Surgeon and MAN-MIDWIFE' over their doors, and are well employed among the ladies. In short, Sir. I am persuaded, if something is not done to put done those multitude of HE-SHE things among us, called MEN-MIDWIFES, MEN-MILLINERS, MEN-STAY-MAKERS, MEN-MANTUAMAKERS, MALE-LADIES' HAIR-DRESSERS, yea, and WASHER-MEN also, who have started up like mushrooms of late; I say, if something be not done to stop this confounding of sex, like the language at the building of Babel, we shall ere long have a race of MALE Ladies' garter-tiers, Ladies' bathers, and I know not what . . . and scarce a truly masculine man, or a real modest woman, will be found.

"Pray, good sir, think of some remedy for this national evil; and, in the application of it you shall not want the assistance of—

"Your obedient Servant,
"Cadwallader Evans."

That the town should have one of these "He-She Things" is another proof of its importance.

Mr. Rootes was a bachelor till September 20th, 1779, when he took to wife by licence—then the "genteel" mode—in the parish Church, Mary Butcher, without doubt a popular and pretty "Elamite," as the late Canon Robert C. Jenkins, M.A., the widely-known, courtly, scholarly gentleman—well-known amongst his intimate friends as the "Abbot of Lyminge"—used to call the inhabitants of this parish.

In April, 1782, their son, William, was baptised, and two years later another, named after his father. Then followed four more—George in 1786, James in '90, Thomas in '92, and Richard born on December 8th, and baptised on December 24th, 1794, his godfather being Stephen Prebble, blacksmith, son of the above "Blacksmith," and William Noble, mine host of the "Rose and Crown," both exceptional men, his godmother being the wife of the former. Then came Mary, the flower nipped in the bud, their only daughter, who, as an infant, was laid to rest in God's Acre in 1797. There was one other son, baptised Edward in 1799, and possibly another John. With such a family Mr. Rootes showed his prudence by being a member of the "Benevolent Society for the Relief of Widows and Orphans of Medical Men in Kent," founded in 1787, by the usual payment of "twenty guineas, being in good health." His family was one of the 25 per cent of the families of members, whose circumstances necessitated the assistance of the society; and it speaks well for the generosity of the members that, during its first twenty years, thirty families had to do the same. Mr. Rootes lived to the age of 62, and was buried on February 7th, 1803.

Then followed *Thomas Noble Elwyn, M.R.C.S.*, whose brother, George, became Clerk to the Justices of the Elham Division of Kent about 1808, and who served the office of Under-Sheriff of Canterbury in 1811. The former year was the one in which Thomas, joined the above Benevolent Society for Medical Men; whilst the latter marked two important changes in his career. First he left Elham for Sandwich to carry on the practice of Robert Curling; then, in November, he journeyed—and it was a journey at that day, at that time of the year; but was he alone?—from that ancient port to Bath, where on the 16th of that month he married, "Elizabeth, eldest daughter of Sam Harvey, brewer of Sandwich, and niece of the late Vice-Admiral Sir Henry Harvey, K.B."

Then came Doctor Peck (or was it Thomas A. Pack?) of whom nothing can be gathered from documents; though he is distinctly remembered by that venerable inhabitant, Mrs. Court—better known locally as "Nurse Court," as having assisted the profession for many years—who attained her ninety-eighth birthday on February 24th last; and who, with a merry twinkle in her eye, is proud of never having been out of Court—though "I have been married"—from her cradle to the present day—her husband being her cousin Stephen; and who saw the Duke of Wellington on his landing at Dover from the Battle of Waterloo.

The practice then passed to *William Pittock*, who took his M.R.C.S.Eng. on May 7th, 1813, and then practised in Maidstone till 1831, when he removed to Elham. Here he practiced for over twenty years, being assisted first by his son, Francis William, who took his M.R.C.S.Eng., on May 4th, 1838, from that time till 1843, when he settled at Sellinge, in Kent; then by William Taylor Tyson—fourth son of Joseph Taylor Tyson, of Canterbury—who became a M.R.C.S. Eng., in September, 1834, and a L.S.A. the following year. In 1845, *Doctor Tyson* married Miss Regden, of Etching Hill, Lyminge; and two years later removed to Church Street, Folkestone, then the fashionable part of that town; rightly judging it would further his interests; and was at once elected Surgeon to the Folkestone Dispensary, now represented by the Victoria Hospital, of which his second son, Joseph Wm. Tyson, F.R.C.P., is one of the Hon. Physicians.

The Elham practice then passed into the hands of *James Beattie*, who took his L.R.C.S.Edin. in 1840, and M.R.C.S.Eng. fourteen years later. He was medical officer of Elham Union and surgeon to the East Kent Mounted Rifles. Dying in 1859, he was succeeded by *Hubert Beadles*, who received his medical training at Westminster Hospital, qualifying M.R.C.S.Eng., in 1857, and taking the L.M., and L.S.A. the following year. Then followed *William Bishop*, a native of Chipping Norton, Oxfordshire, a popular student at University College Hospital; who not only devoted himself to his work within the hospital, but was a devotee in defence of the profession; being the ringleader of that gallant little band, which set out one evening from the hospital to whitewash a certain lion, erected as an advertisement of a patent pill. The work was all but completed when "a gentleman in blue" appearing, the valiant, remembering that "discretion is the better part of valour," took to their heels, soon increasing the distance between them and their pursuer, who doubtless, having partaken of a good supper provided by a kind-hearted cook at the expense of her master, soon gave up the chase. In 1868, he qualified M.R.C.S.Eng., and three years later took the L.S.A.Lond., and L.R.C.P.Edin. Having gained some valuable practical experience as Assistant Surgeon of Sirhowy Iron Works in Wales, he settled in Elham, and shortly after married the sister of the present Lord Mayor of London. Besides holding the various local medical appointments, he was a member of the Royal Commission on Horse Breeding, and Hon. Secretary of the East Kent Foxhounds for over twenty years. He was a keen and true sportsman, loving all nature; his fellow-man, the robin and the wren, which he always greeted as "God's Cock and Hen," to the mushroom, which at one time he cultivated to such perfection that he obtained a shilling a pound in Covent Garden for them. The respect with which he was held by peer and poor was shown when his body was laid by the side of his friend, the late Walker Wodehouse, M.A., the beloved vicar of the parish, who for over half a century had "neither changed, nor wished to change, his place." The practice, traced for some two hundred and twenty years, is now in the able hands of Gordon H. Hackney, who also received his medical training at University College Hospital, qualifying M.R.C.S.Eng., and L.R.C.P.Lond. in 1901.

MEDICAL NEWS IN BRIEF.

A Vegetarian Manifesto.

The present season of discontent is usually made glorious in autumn by the sea serpent, the giant gooseberry, and "pater familias." It is still further enriched this year by the appearance of the following *naif* document which is forming a splendid "fill-up" for sterile news-sheets.

Medical Manifesto on Vegetarianism.

We, the undersigned medical men, having carefully considered the subject of vegetarianism in its scientific aspects and having put its principles to the practical test of experience, hereby record our emphatic opinion that not only is the practise based on a truly scientific foundation, but that it is conducive to the best physical conditions of human life. The diet of vegetarianism provides all the constituents necessary to the building up of the human body, and those constituents as proved not by the misleading tests of the chemical and physical laboratory, but by the experience of numerous persons living under normal conditions are at least as digestible and as assimilable as the corresponding substances obtained from flesh. We, therefore, claim vegetarianism to be scientifically a sound and satisfactory system of dietetics. Moreover, considering the liability of cattle and other animals to ailments and diseases of various kinds, and the pure character of food obtained from vegetarian sources, we are convinced that abstinence from flesh food is not only more conducive to health, but from an æsthetic point of view is incomparably superior.

Robert Bell, M.D., George Black, M.B.Edin., A. J. H. Crespi, M.R.C.S., H. H. S. Dorman, M.D., Albert Gresswell, M.A., M.D., Walter R. Hadwen, M.D., L.R.C.P., M.R.C.S., J. Stenson Hooker, M.D., Augustus Johnstone, M.B., M.R.C.S., H. Valentine Knaggs, M.R.C.S., L.R.C.P., Alfred Bolsen., M.D., Robert H. Perks, M.D., F.R.C.S., John Reid, M.B., C.M., George B. Walters, M.D.

It is a great thing to belong to a free, catholic, and tolerant profession!

Medical Man Shot by Patient.

Chapeltown, one of the fashionable suburbs of Leeds, was startled on Saturday morning by the news that one of its best known medical practitioners had been murdered by a patient.

Dr. Walter Clapham Hirst had among his patients a man named John William Harrison, aged about 40, who had recently become well known in the district owing to his eccentric habits. On Friday night last he visited Dr. Hirst's consulting room, and was then very strange in his manner, but after an hour's talk with the doctor he became quieter and left. Nothing more was heard of him until yesterday morning, when he again proceeded to the doctor's residence. He reached the house about six o'clock and Dr. Hirst appeared at the door in answer to the night bell. As soon as he opened the door Harrison remarked: "You are Dr. Hirst," and produced a revolver and fired twice at the doctor, who fell on the doorstep.

The sound of firing roused Mrs. Hirst and some neighbours, but before assistance came Harrison had turned the weapon on himself, and, firing into his mouth, fell by the doctor's body, his head being completely shattered. Mrs. Hirst found her husband still alive, but he was mortally wounded, for one of the bullets had struck him under the left side of the breastbone, another penetrating the chest a little lower down on the right side.

It is clear that Harrison's mind was affected. In a letter received by a friend Harrison said:—

"I was suffering terrific, and doctor struck me on both knees, which brings on epileptic fits. It was murder to me. He has killed me. I was all right before, but now am lost. The pains and fits are terrific. He has killed me wilfully and deserves punishment. He deliberately struck me on both knee-caps last Monday. It was murder. Farewell, old friend. No more happy hours in your garden."

Harrison added: "I have given the motive of the crime to Mr. ——."

A pathetic feature of the tragedy is that Dr. Hirst was married about six weeks ago to Miss Nellie Oldroyd, the daughter of a manufacturer. The bridal couple only returned a week ago from their honeymoon tour in Switzerland. Dr. Hirst, who was 28 years of age, belonged to Dewsbury. He was an M.B. of London, and an old student of Leeds and St. Bartholomew's.

Death Under Chloroform.

An inquest was held at Bredbury Hospital, last week, on the body of Emily Riding, three years old, operated on for double club-foot.

Dr. Thomas Birch, resident medical officer, said the operation was successfully performed, and the child was a fit subject for the administration of chloroform. The next morning, however, she showed symptoms of chloroform poisoning. She became unconscious, and died the same evening from cardiac failure produced by the delayed action of chloroform. The witness added that the child was not given very much chloroform, and the quantity had nothing to do with the fatal result. Dr. Birch added that he made a *post-mortem* examination which confirmed his conclusion. The deputy-coroner, Mr. Birch, pointed out that he had not given permission for a *post-mortem* examination to be made. He also mentioned that the child died on Thursday, and he only got information of its death Sunday morning. He did not think that the doctor was justified in giving his certificate in a case which was not death from natural causes, and, as might have been expected, the registrar refused the certificate.

The doctor explained that he was under the impression that in a case of that kind he was authorised to make a *post-mortem*, and that his evidence would not be complete without it.

The jury returned a verdict in accordance with the doctor's evidence in regard to the cause of death.

Death Under Ether.

Mr. Walter Schröder conducted an inquest on the 27th inst. at St. Pancras, on Kate Hartshorn, aged thirty-two.

The deceased underwent a slight surgical operation at the Royal Free Hospital for cancer, of the breast on the 17th inst., after which she was sent home in a cab. Subsequently it was discovered that a more drastic operation was necessary, and she was re-admitted to undergo this.

Dr. Charlotte Alice King, house-surgeon at the hospital, stated that on the deceased's re-admission the operation was deferred until the following Friday. It occupied two hours and a half, and during two hours ether was being administered. Mr. Cunning, one of the visiting surgeons, performed the operation. Signs of cardiac failure were observed, and the administration was discontinued, recourse being had to stimulants. Ultimately she expired, and, from the autopsy witness made, she concluded that death was due to cardiac failure, consequent on the shock of the operation.

Dr. Florence Elizabeth Willie, senior anæsthetist, said that the inhaler held nearly five ounces of ether. If she had a similar case she should, perhaps, have recourse to a stimulating infusion earlier during so prolonged an operation. Witness had administered anæsthetics in at least a thousand instances.

The jury returned a verdict of death by misadventure.

Inquest on Malvern Medical Man.

An inquest was held at Malvern, on August 23rd, by the District Coroner into the circumstances attending the death of Dr. Edmund Antrobus, of Great Malvern, who died after taking an injection of a sleeping draught. Mr. Guy Antrobus, brother of the deceased, who was sleeping in the same room at the time, said he heard Dr. Antrobus moving by the dressing-table. He got out of bed to see what was the matter. Deceased stumbled. Witness got him into bed and sent for doctors, whose efforts were, however, unavailing, death occurring within about an hour and a half. Deceased had been seriously ill from blood poisoning, contracted two years ago, but had seemed better lately. Evidence was given that at a *post-mortem* examination it was found that an exceptionally large dose of a narcotic containing opium had been taken, and that this was the cause of death. Several pricks, such as might be caused by a hypodermic syringe, were found. The jury found that the deceased had died from an overdose of narcotic, self-administered, to produce sleep. They expressed sympathy with the relatives.

Society for the Study of Inebriety.

The Second Norman Kerr Memorial Lecture, held under the direction of the Society for the Study of Inebriety, will be delivered by Robert Welsh Branthwaite, Esq., M.D., H.M. Inspector under the Inebriates' Acts, on Tuesday, October 8, at 8.30 p.m., in the Hall of the Royal Society of Medicine, 20 Hanover Square, London. The subject of the lecture will be "Inebriety—Its Causation and Control."

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT PATHOLOGICAL LITERATURE.

Vaccine Treatment and Opsonic Control.—A series of papers of great importance appears in the June-July number of the *Johns Hopkins Hospital Bulletin.* Taken together they seem to place in fresh perspective the practical relation of opsonic control to vaccine treatment. I.—Cole and Meakins relate their experience of twenty cases of gonorrhœal arthritis treated by vaccines, and state their general conclusions arising therefrom. They deprecate the publication of the histories of isolated cases in which the writer has undertaken the treatment with great enthusiasm, and it is as a contribution towards wider statistics than are yet available that they publish their examination of a small group of cases of one disease. In their technique they followed with slight modifications the methods of Wright. The initial dose of dead gonococci was usually three hundred million, and the amount was gradually increased until a dose of one thousand million cocci was administered. No ill-effects were encountered, though a slight local reaction of pain, tenderness and redness always occurred twelve to twenty-four hours after the first dose. General constitutional disturbances following the injections were very rare. The general course of the opsonic charts is similar to that observed by Wright and his collaborators, but the writers did not find the "negative phase" at all marked. The ill-effects of a "negative phase" were not observed clinically, and a cumulative "negative phase" was never observed. The notes of the cases treated would seem to justify a stronger conclusion than the very moderate statement of the writers that their "impression is that the vaccine treatment as carried out, has been of distinct value." As regards the value of opsonic control, the writers point out that "considering the present almost certain inaccuracy of opsonic technique, and the absence of sufficient evidence as to the *rôle* of opsonics in immunity, it hardly seems advisable that the control of the administration of vaccines by the estimation of the opsonic index should be persisted in. We do not feel," they go on, "that the danger of cumulative negative phases is a real one. In no case have we seen the administration of gonococcus vaccine do harm, and we feel that these cases offer sufficient justification for the treatment of gonorrhœal arthritis by means of vaccines in doses of 500 to 1,000 million, administered every seven to ten days."

II.—Jeans and Sellards deal with tuberculin treatment and opsonic control. In technique they have made some important advances. Instead of grinding the dead bacilli in an agate mortar as recommended by Wright, they emulsify the living bacilli by rubbing them up in salt solution with a heavy platinum wire or a small glass rod. The emulsion is then sterilised by exposure to direct sunlight for ten hours. In the preparation of the smears they are fixed with methyl alcohol for thirty seconds, and stained with carbol-Fuchsin for one to two hours at 37° C., recolouring with 95 per cent. alcohol for three to four minutes, and counterstaining with saturated aqueous methylene blue for five to ten minutes. The writers note very great variations in the counts obtained from the same preparations and some from the same slides, and they regard the limits of error as much wider than has been hitherto supposed. Thus, by dividing a slide into three sections by transverse lines it was found that the section at the end of the smear contained 282 bacteria, the middle section 107, and the first section 140 bacteria in 50 leucocytes. In other cases they got from the same serum indices varying from 0.4 to 2.34. They think, therefore, that it is probable that large differences in indices mean differences in opsonic control, but they do not believe that small differences can be held to have any signification. As regards diagnosis, they have employed the opsonic method in a considerable number of cases without obtaining satisfactory results. They append the clinical notes and opsonic charts of nine cases of tuberculosis treated by vaccines, which justify their statement that the results obtained by the administration of T. R. tuberculin in small, infrequent doses as Wright advises, have given encouraging results.

III.—Wass reports certain theoretical studies in opsonics. In the first place he attempts to decide whether it is possible to raise the opsonic power of the serum beyond the very low limits with which Wright has, for therapeutic purposes, contented himself. The method employed consisted in repeated progressive inoculation :—(1) intravenously with dead staphylococci; (2) subcutaneously with living staphylococci; (3) subcutaneously with dead staphylococci. The animals employed were rabbits. It is not necessary to describe in detail the experiments which led to the conclusion that no high degree of opsonic immunity such as is possible in antitoxic and bactericidal immunity can be produced in rabbits by ordinary inoculation procedures with *staphylococcus aureus.* He next discusses the trustworthiness of Wright's method of estimating the opsonic variations. He shows by many examples the variations between different estimations of the same serum, and the variations shown even by normal serum. Thus, in the case of one normal human serum, thirteen observations showed variations between the limits of 0.52 and 1.95, and of another between 0.42 and 1.66. He is therefore led to conclude that *none of the present methods of estimating the opsonic control of the blood seem sufficiently accurate to be of practical value.* He suggests "that further efforts should be expended in finding a reliable technique for clinical purposes rather than in continuing to pile up statistics which are so inaccurate as to be misleading."

IV.—Klein discusses the subject of opsonics in typhoid immunity, and he shows that the opsonic index, as determined by Wright's method, bears no relation to the degree of immunity present, at any rate in the higher grades of immunity. The index seems to rise with the development of immunity, but with the further development it drops. He suggests as an explanation of this fact that the ambaceptor-laden bacteria are much more quickly digested by the leucocytes, and therefore rapidly become invisible.

V.—Russell discusses the specificity of opsonics and concludes :—(1) Following injections of bacterial vaccines, the increase of opsonics is probably due to the formation of immune opsonics which re-act specifically; (2) in saturation experiments with normal sera we are dealing with normal as common opsonics, and these are not specific, since they can be removed by saturation with any one of a considerable number of bodies; (3) in saturation experiments with immune sera we have both the immune and the common opsonics present; the former is quite specific, while the latter is not; (4) *B. pyocyaneus* is quite susceptible to spontaneous phagocytosis.

The consensus of opinion which is to be gathered from the contributions of these several workers attacking the problem from separate points of view is of the utmost importance. On one point there is unanimity *that the estimation of the opsonic index by Wright's method is open to such error as to be useless for diagnosis or treatment.* On another point, those who deal with the subject of treatment are agreed *that vaccine treatment has given such promising results as to justify its continuance.* If these conclusions be justified then a great stimulus to vaccine treatment has been given by freeing it of the dead weight of opsonic control. R.

Diphtheria Bacilli in Normal Throats.—Anna van Sholley publishes a painstaking investigation on the presence of diphtheria bacilli in the throats of healthy children (*Journal of Infectious Diseases*, June, 1907). She examined in the hospitals of New York the throats of 1,000 children, none of whom had been exposed to the infection of diphtheria. From 56 of the 1,000 cases (5.6 per cent.) diphtheria-like bacilli were separated, and in 18 of these (1.8 per cent.) the organism was true virulent Klebs-Löffler bacillus. She also examined the throats of 202 persons who had been in contact with cases of diphtheria. From them diphtheria-like bacilli were isolated 20 times, 14 virulent and 6 non-virulent, or a proportion of 7 per cent. of contacts were infected with the Klebs-Löffler bacillus. The proportion of virulent and non-virulent is, therefore, exactly reversed in the case of contacts from that in the case of non-contacts. The author concludes :—(1) Diphtheria-like organisms are present in a certain number of apparently normal throats, even where exposure to infection cannot be traced. (2) A certain proportion of these organisms (in her cases about one-third) are virulent, and the persons thus infected are a potential source of danger to the community while about two-thirds of the organisms are not true diphtheria bacilli, and are probably harmless. (3) The other conditions being the same, virulent Klebs-Löffler bacilli are found in the mucous membranes of those exposed about four times as often as in those apparently not exposed. (4) Mild sore throats and "colds" with bloody nasal discharge, such as are fairly common in children, should not be lightly considered. Cultures should be taken, and if diphtheria-like organisms are found, their virulence should be tested. R.

Implantation of Cancer.—Butlin in a popular address discusses (*British Medical Journal*, August 3rd, 1907) under the term "The Contagion of Cancer in Human Beings: Autoinoculation," the phenomenon usually known as implantation. He enumerates a fair number of cases which might be explained in this way though some of them are capable of other explanation; but he by no means refers to all the cases well known in the literature of cancer. The sites in which he believes he has evidence of implantation taking place are the vulva, the larynx, the lips, the lower jaw, the uterus and vagina, and some others where the affected points were further distant from each other. R.

Moser's Serum in Scarlatina.—Langowoi and Egis have treated four hundred cases of scarlatina with Moser's serum and have come to the following conclusions :—(1) In the treatment of severe cases the mortality is reduced by the use of the serum from 47.1 per cent. to 16.1 per cent. (2) The serum has undoubted anti-toxic properties. (3) It is of little or no use against the complications of scarlatina. (4) To be of any use it should be injected within the first three days of the sickness, or at latest on the fourth day. (5) The temperature usually falls by crisis when the serum has been given early. In complicated cases, however, a critical fall is not noted. (6) The usual dose of the serum for an adult is 200 c.cm., and for children about half that amount. (7) The different specimens of serum differ widely in their anti-toxic properties. (8) Prophylactic small doses seem to diminish the susceptibility to scarlatina. M.

Chlorosis in Infants.—According to Leenhardt (*Zentralbl. fur Inn. Med.*, 1907. No. 30.) true chlorosis is to be met with in the earliest years of life. He bases this assertion on his own observation of sixteen cases in children between twelve and eighteen months old. The resemblance of the cases to the form of anæmia met with at puberty is often quite obvious. The children are very pale, but with normal development, and are generally in a good nutritional state. With the exception of cardiac murmurs, and murmurs in the vessels of the neck, nothing abnormal can be detected. The liver, spleen and lymph glands are of normal size, but usually there is constipation. The red and white corpuscles are normal in number, both relatively and absolutely, but there is a great deficiency of hæmoglobin. The resemblance to chlorosis of later life is heightened by the fact that improvement rapidly occurs under a course of iron. M.

The Dependence of Respiration upon Pressure Conditions.—As a result of a large number of experiments and from the fact that bilateral pneumo-thorax is not necessarily fatal, Hellin (*Mitteilung a. d. Grenzgebiet du Medizin.* Bd. xvii. Heft, 3 u 4,) claims that the hitherto received theory of pulmonary movements is incorrect. Lung movements he maintains cannot depend upon the difference of pressure upon the inner and outer aspects of the lungs respectively. Clinical observations also agree with this inasmuch as a collapsed lung can again expand even in the absence of a negative pressure. Lungs also may collapse without any preexisting change in the pressure conditions. According to Sauerbruch's investigations in cases of unilateral pneumothorax, it is not the collapse of the lung that proves fatal, but the sudden failure of respiration. Hellin concludes that expiration is not the result of the pressure of the thorax, and that inspiration is by no means necessarily influenced by the adhesion of the lungs to the chest wall. M.

The Blood Pressure in Athletes.—Gordon has investigated the blood pressure before and after exercise (*Edinburgh Med. Journal*, July, 1907). The subject of his observations was a champion club swinger, who had arranged to swing his clubs for twelve hours continuously on six consecutive days. The individual was found to be a perfectly healthy athlete æt. 38. The observations were made by means of a Riva Rocci and an Erlanger's sphygmomanometer; the pressure being taken immediately before and immediately after the exercise. It was found that the pressure was on each occasion raised some 15 mm. after the exercise, but this rise was invariably gone by the next morning. More violent exercise, such as playing football, seems. on the other hand to cause a fall of pressure of about 25 mm. Hg. M.

The Influence of Smoking on the Circulation.—Hesse has systematically examined (*Deutsch. Archiv. fur Klin. Med.*, Bd. 89., p. 565) the blood pressure, systolic and diastolic, and the pulse frequency in smokers, before and after smoking, with the object of determining the influence excited by nicotine on the circulation. He finds that in almost every case a marked rise of blood pressure takes place after smoking, and that this is accompanied by an increase in the pulse rate. The greater the age of the individual, the more marked is the rise. The rise, moreover, is much more evident on the systolic pressure, than on the diastolic. It occurs quite quickly, but does not persist long. Sometimes the aortic sound becomes markedly accentuated during smoking. Hesse concludes that the general effects of nicotine on the circulation are stimulating rather than the reverse, and he thinks that some of the cardiac troubles met with in smokers may be the result of cardiac overstrain. M.

The Metabolism in Arthritis Deformans.—King has studied exhaustively the metabolism of a case of arthritis deformans (*Johns Hopkins Hospital Bulletin*, July, 1907, p. 274), and has come to the following conclusions :—(1) There is undoubtedly taking place in the organism an acidosis, due to organic acids and mild in nature. The actual organic acids were not identified, but it was shown that neither diacetic acid or oxyacetic acid were present; (2) the acidosis is combated chiefly by an increased ammonia production; (3) throughout the course of the experiment there was a retention in the body of calcium, magnesium and phosphates; (4) there was no evidence from the urine of any acid intestinal putrefaction, and the ratio of the aromatic and perfumed sulphates remained about normal; (5) an increase in the organic phosphates in the urine coincides with the increase of organic acids; (6) the disturbance in the elements maintaining the alkalinity of the body was very slight. M.

NOTICES TO CORRESPONDENTS, &c.

☛ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

SOUTH WALES.—We have protested again and again against the habit of journals calling quacks, herbalists and abortionists "doctor," but it seems to make but little difference. The sub-editor and the reporter of the ordinary daily newspaper have little care but for what will make a good head line, and we must trust to time and education to teach them the difference between a quack and a qualified man.

THE ETIQUETTE OF CONSULTANTS TOWARD GENERAL PRACTITIONERS.

GENERAL PRACTITIONER.—The relations between Surgeon B and your patient appear to us to depend on the position in which Surgeon B was placed at the first consultation. If you were prepared to take the management of the case, and if Surgeon B was called in merely to give his opinion at the time and to prescribe treatment, he has acted incorrectly in communicating any facts to the patient save through you, and he was not entitled to see the patient at his house, even if the patient requested him to do so, unless you sanctioned such an arrangement. If, on the other hand, it was arranged at the first consultation that Surgeon B should take on the management of the case, he is, of course, entitled to adopt any precautions he thinks necessary to acquaint the patient of the course of his case, and to see him as often as is necessary. At the same time, however, it would only be courteous and proper on his part to acquaint you at once with any new developments.

DR. G. F. S.—Your communication came to hand as we were "at press"; it will appear in our next.

WEED.—We know that certain efforts have been made to rid tobacco of nicotine, but we believe they have never been thoroughly successful, and no nicotine-less tobacco that we know of has been placed on the market. Dr. Lesieur, of Lyons, is an enthusiast on denicotinisation, and he would doubtless reply to any letter you might address to him.

MR. HY. S.—See reply to Dr. G F. S.

HUMANITARIAN.—Thank you for brochure, which we already know and value. We fancy you cannot have read all our comments, as imprisonment for debt was distinctly and specifically reprobated by us. We hold in horror the practice of sending working men to prison for trumpery debts, and wish you every success in your efforts to put an end to it.

HOUSE SURGEON.—Yes, it has been definitely decided by the Committee that women doctors will be considered no longer eligible for the post.

G. B.—We think that, so far as four-fifths of Ireland are concerned, your religion will effectually prevent you from obtaining any such post as you seek, no matter what your qualifications. So far as the remaining fifth is concerned, your religion might not be a bar, but we doubt if your qualifications would be taken into consideration unless there was no local candidate in the field. Temporary appointments therefore, as a means of leading up to a permanent appointment, do not appear to possess a high value. It may be some consolation to you to know that the appointments you seek are universally considered to be not conducive to the future happiness or welfare of their holders, and that under the present condition of things you will be far better elsewhere.

Vacancies.

Bridgnorth and South Shropshire Infirmary.—House Surgeon. Salary £100 per annum, with board and lodgings in the Infirmary. Applications to the Hon. Secretary, the Infirmary, Bridgnorth.

West Norfolk and Lynn Hospital, King's Lynn.—House Surgeon. Salary, £100 per annum, with board, residence, and washing. Applications to the Chairman at the Hospital.

Leicester Corporation.—Isolation Hospital.—Resident Medical Officer. Salary £120 per annum, with board, lodging, and washing. Applications to C. Killick Mallard, M.D., Town Hall, Leicester.

County Borough of Salford.—Fever Hospital.—Assistant Medical Officer at the Ladywell Sanatorium, Salford. Salary, £150 per annum, with apartments and board. Applications to L. C. Evans, Town Clerk, Town Hall, Salford.

Egyptian Government.—Kasr El Ainy Hospital.—Resident Medical Officer. Salary £250 a year, with quarters, servants, washing, coal, and light. Applications to the Director-General, Public Health Department, Cairo.

York Dispensary.—Two Resident Medical Officers. Salary, £120 a year, with board, lodging, and attendance. Applications to W. Draper, Esq., De Grey House, York.

Loughborough and District General Hospital and Dispensary.—Resident House Surgeon. Salary £100 a year, with furnished rooms, attendance, board, and washing. Applications to Thos. J. Webb, Secretary, Loughborough.

Carlow District Asylum.—Resident Medical Superintendent. Salary, £350 per annum. Applications to John Keenan, Secretary Joint Committee.

National Maternity Hospital, Holles Street, Dublin.—Intern Assistant Physician. Salary, £50 per annum. Applications to the Secretary, Holles Street.

Middlesex County Asylum, near Tooting, S.W.—Fourth Assistant Medical Officer. Salary, £150 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

Southwark Union, London.—Second Assistant Male Medical Officer. Salary, £100 per annum, with board, lodging, and washing. Applications to Howard C. Jones, Clerk, Union Offices, John Street West, Blackfriars Road, S.E.

Devonshire Hospital, Buxton.—House Surgeon. Salary, £100 per annum, with furnished apartments, board, and laundry. Applications to the Secretary.

Canterbury County Borough Asylum.—Medical Superintendent. Salary, £350 per annum, with unfurnished house, coal, light, washing, garden produce. Applications to the Town Clerk, 15 Burgate Street, Canterbury.

Cambridgeshire, etc., Asylum.—Second Assistant Medical Officer. Salary, £120 per annum, with board, lodging, and attendance in the Asylum. Applications to T. Musgrave Francis, Clerk to the Visitors, Cambridge.

Appointments.

ASH, EDWIN L., M.B.Lond., M.R.C.S.Eng., Clinical Assistant at Great Northern Central Hospital, London, N.

BALL, W. GIRLING, F.R.C.S., Assistant Surgeon to the City of London Truss Society.

COLLINS, E., M.R.C.S., L.R.C.P., District Medical Officer of Bishop's Stortford Union.

GORHAM, P. C., L.R.C.P., L.R.C.S., Certifying Factory Surgeon for the Clifden District, co. Galway.

ELLISON, FRANCIS CHARLES, M.D.Dub., Resident Medical Superintendent, Mayo County Asylum, Castlebar.

GASK, G. E., F.R.C.S., Surgeon to the City of London Truss Society.

HEBB, J. H., M.B., B.Ch.Oxon., B.A., District Medical Officer of Bicester and Headington Unions.

HUSTLER, G. H., M.B., Ch.B.Leeds, Government Medical Officer for Fiji.

LAWSON, T. C., M.R.C.S., District Medical Officer of Stratton Union.

MAIR, GAVIN D., M.B., B.Ch., Resident Medical Officer, Royal Albert Hospital, Devonport.

PAUL, V. G. J., M.R.C.S., L.R.C.P.Lond., District Medical Officer of the Tendring Union.

RIDLEY, T., M.B.Melb., Assistant Resident Medical Officer of the Midwifery Department of the Women's Hospital, Melbourne.

WALFORD, H. R., M.R.C.S., L.R.C.P., Assistant Surgeon to the Coventry and Warwickshire Hospital, Coventry.

WILLIAMS, E. G. H., M.R.C.S., L.R.C.P., District Medical Officer of the Droitwich Union.

Births.

EDWARDS.—On August 28th, at Westcroft, Privett Road, Gosport, the wife of Lieut. G. B. Edwards, R.A.M.C., of a daughter.

LYLE.—On Aug. 30th, at "Uplands," Bournemouth, the wife of Lieutenant-Colonel Allan Lyle, R.A.M.C. (retired), of a daughter.

MACCARTHY.—On August 26th, at Glenaveena, Clooney Park, Londonderry, the wife of Brendan MacCarthy, M.D., D.P.H., Med. Inspect. L.G. Board, Ireland, of a son.

PARSONS.—On August 26th, at 26 Parliament Hill Mansions, N.W., the wife of W. B. Parsons, M.R.C.S., L.R.C.P., of a daughter.

WALKER.—On August 21st, at Yewdale, Lee-on-the-Solent, Hants, the wife of Lewis Walker, M.D.Lond., of a daughter.

Marriages.

CLARE—DORIN.—On August 29th, at All Saints' Church, South Lambeth, the Rev. Mervyn Clare, Minor Canon of St. Canice's Cathedral, Kilkenny, only son of the Rev. Mervyn A. Clare, of Blackheath, to Florence Margaret (Daisy), only daughter of A. F. L. Dorin, M.R.C.S., of 344, Clapham Road, London.

RENTON—BORMAN.—On Sept. 2nd, at All Saints' Parish Church, Bloomsbury, London, Maurice Waugh Renton, M.D., of The Bridge House, Dartford, to Ezma Olivia Borman, daughter of Allen Borman, Esq., Alexandria, Egypt.

WRIGHT—TAYLOR.—On August 28th, at the Parish Church, Lyons, Hetton-le-Hole, near Durham, Archibald Francis Wright, M.B., third son of the late Strethill H. Wright, M.D., of Ganarew, near Monmouth, to Dorothy Mary, daughter of the Rev. R. H. Taylor, D.D., Rector of Lyons.

Deaths.

CROFT.—On August 26th, at Cheam, Surrey, Anna Maria Croft, widow of the late Robert Charles Croft, M.D.

INGLIS.—On August 29th, at 2 East Ascent, St. Leonards-on-Sea, Wilhelmina Simson, wife of Arthur Stephen Inglis, M.D.

WIGGINS.—On August 25th, at Gt. Missenden, Eric, the eldest son of Charles Wiggins, M.R.C.S., L.R.C.P.Lond., of 117 Ladbroke Grove, London, aged 14 years.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXV. WEDNESDAY, SEPT. 11, 1907. No. 11

NOTES AND COMMENTS.

The Apprenticeship of Medicine.

OF all the learned professions it may pretty safely be asserted there is none in which the aspirant finds himself faced with greater obstacles than in that of medicine. After being tested as to his general education by preliminary examination he has to settle down to five years of hard and systematic study. At certain intervals his knowledge of the various subjects included in the curriculum is severely tested, and it is only when he has succeeded in satisfying his examiners on all points that the desired qualification to practise is granted. In some instances the student is not able to pass his examinations within the allotted five years and has to spend a further period in study. Oftentimes when he is ambitious of taking the higher degrees and qualifications and of embarking in consultant or specialist practice he deliberately makes up his mind to two or three extra years of pupilage. What with multiplicity of subjects and increasingly higher standards, the students' career, as above outlined, connotes the expenditure of a vast amount of time, energy and money, ere the goal is reached and the fully fledged practitioner enters upon the serious work of his life.

A Noble Profession.

THEN the official sanction having been acquired, the newly fledged practitioner of medicine is launched upon the sea of professional life. The right has been conferred upon him by the State to intervene in the unceasing struggle of mankind against disease and accident and other adverse influences of environment. A cynical French physician, writing some time ago in the columns of THE MEDICAL PRESS AND CIRCULAR, reminded a young friend about to commence practice that his diploma was written on the skin of an ass. On this side of the Channel it would probably be engraved on that of a calf, but in either case it would not interfere with Dr. Cornu's advice to his correspondent not to resent the inference, but rather to regard it as a tacit injunction to be patient, courageous and gentle. For these are high qualities, and they are demanded of all who would be worthy of a noble profession. Yet the conditions of society are such that mere abstract nobility of the kind involved will not become a satisfactory footing for the struggle for existence.

The Financial Aspect of Practice.

THERE is a financial side of the picture, the neglect of which will sooner or later spell ruin to the most ardent enthusiast in scientific work, unless, indeed, he is fortunate enough to be in possession of an independent income. The student can afford to follow science for science's sake; the practitioner, on the other hand, has to practise art for something more than art's sake. It is all very well for medical men, who, by the way, are usually those in possession of a comfortable income, to deplore the spread of trade-union ideas and to deprecate the commercial spirit amongst their medical brethren. There is nothing dishonourable in taking a proper collective care of the financial factors of the situation, which have, unfortunately, in the past been often disregarded, with most disastrous results. It is not as if the State in conferring the right to practise the healing art upon properly qualified men had taken care to protect them against the inroads of unqualified pretenders. Members of Parliament are far too apt to consider that the State has granted an enormously valuable monopoly to the profession and is entitled in return to exact as much gratuitious service as can be wrung from the profession. The more precise statement of the situation is that the State has imposed certain restrictions upon medical men so as to ensure a proper supply of skilled practitioners in the interests of the public. By permitting the competition of a whole host of quacks and patent medicine vendors the State has betrayed the medical profession and abandoned with cynical shamelessness the wholesome principle of the protection of the public safety.

An Instance!

THE State, as we have already said, exacts many gratuitous services from the medical profession. As an example may be taken the death certificate, which is signed by the medical attendant of deceased, and for which no fee is payable. The legal document in question is of importance in many ways, and may form the crucial proof in various lawsuits. From no other profession in the world would the State attempt to exact a similar substantial service without the payment of a suitable fee in return. One may fancy the utter contempt with which the lawyers would resent any attempt to exploit their profession in a similar way. Such and such a fee would be demanded for signature, correspondence would be charged at the rate of six and eightpence a letter, and other work in connection with the required document would be entitled to corresponding rates of remuneration. When it comes to medical men, however, the element of humanitarian kindness is in some extraordinary way confused with the principles that govern an ordinary business transaction, so that the matter usually ends by the required service being rendered "free, gratis, and for nothing." In many ways this must, in the long run, prove a bad bargain for the community, for it is only by maintaining the medical profession in a position of honourable independence, from the point of view of average professional income, that society can hope to maintain a high general standard of professional conduct and competence.

Mr. John Burns and the Birth Certificate.

No more glaring instance of the attitude of Parliament towards the monetary interests of the medical profession could be obtained than that afforded by the recent Notification of Births Bill. Under the guidance of Mr. John Burns the measure has passed into law. It provides for the future notification of all births, an obviously salutary measure, but it makes no provision for the payment of the medical man who sends the necessary intimation. At one stage of the proceedings in the Commons it was determined to pay the medical attendant the magnificent sum of one shilling for each signature! At a later stage of the proceedings, however, even that frail sum vanished into thin air, and Government, following the hallowed precedent of centuries, have framed a law whereby the medical practitioner, under pain of various penalties, is compelled to sign a responsible document giving information obtained *in his professional capacity* without fee or reward. The incredible meaness of this transaction is not what one would have looked for from the President of the Local Government Board, who, of all men, we should expect to recognise the principle that the labourer is worthy of his hire. The medical members of Parliament in the House protested against the measure, but they were not numerically strong enough to prevail. The lamentable lack of medical representatives in the Commons was never more disastrously in evidenece than in the passage of Mr. John Burns' memorable Notification of Births Bill.

The Moral of the Matter.

The above is written in no spirit of mere discontented grumbling or of unbelief in the future welfare of what is justly termed a "noble profession." It is written, however, in the firm belief that Heaven helps those who help themselves. From that standpoint we would urge the medical student from the outset of his career to pay careful attention to all organisations that are directed to the task of protecting the material interests of the profession to which he belongs. There are various ways in which the general welfare of medical men may be forwarded. In the forefront of these agencies we should place that of legislation against quacks and quackery. For many years past it has been our mission to urge the desirability of such preventive action not only in the interests of medical men but also in those of the great outside public. Of late we have added to our programme the suggestion of a Royal Commission to enquire into the terrible abuses and injury sustained by the public at the hands of quacks and patent medicine vendors. We are glad to say that the pharmaceutical profession, as a whole, is making efforts in the same direction. During the year we hope to bring this matter of a Royal Commission before the profession and the public in concrete form.

For the Purpose of Acquiring Manual Skill.

The attitude of the State—*alias* the community—towards medical men is curiously illustrated by the laws passed to control vivisection. The very title of the measure—"The Cruelty to Animals Act"—begs the question, because it tacitly implies that all vivisection is cruel. With the merits or demerits of the controversy we are not here concerned. Briefly the attitude of scientific medicine is that experiments on living lower animals are necessary to elucidate many processes of physiology and pathology; that they have rendered priceless service in the past to medical progress; and that, properly guarded, they are absolutely warranted from a moral point of view in the interests of mankind. In the above-mentioned Act experiments calculated to give pain to living vertebrate animals are prohibited under various specific restrictions. Amongst the latter is one that says they must not be performed for the *purpose of acquiring manual skill!* A man may maim rabbits, hares, and partridges *ad libitum* until he becomes a good shot—but a surgeon must acquire his skill from patients. So says the law—the wise law—the law passed to satisfy the sentimental anti-vivisectionist. The satire of it all is that even anti-vivisectionists want surgical operations, and then—then—why, they have them, and their lives are saved as the outcome of vivisection!

Tact.

Many things wanted to ensure success in practice are not taught in the schools. Devotion to duty is one of them; not only the patient self-sacrifice, and the holding to right because it is right, but the less exalted form which is prized by the public, namely, that of promptitude, and of careful attention to the history of symptoms, however detailed, minute, and wandering. The latter point is one of the manifold skilful strokes in the game that in their entirety constitute that evasive quality which we all know as "tact." Sooner or later, it may be at the cost of dire experience, that faculty has to be acquired by the medical man who would succeed in the exercise of his profession. To quote once more from Dr. Cornu, "Practising for the public an art which it is incapable of judging, you must not hope to create an impression by your knowledge of disease, but by your knowledge of men. The more illusions you have brought into your career the more will the reality have bruised your delicacy of intelligence and sentiment, the deeper will be your fall, and the more dangerous the depression which experience is holding in wait for you."

The Rosy Side.

There is a rosy side to the professional life of the medical practitioner, in spite of quacks and quackery, of anti-vaccinators and anti-vivisectionists, of bad debts, of harassing work, of hospital competition, and of the score of other rocks and shoals that strew the sea of practice. The profession is honourable and intellectual: it is one becoming the traditions and the character of a gentleman: it is humane, charitable, it is progressive, it is intellectual, and, above all other callings in life, it is essentially human. Well may the line of Terence—*Homo sum, humani nil a me alienum puto*—be adopted by the liberal-minded and zealous practitioner of medicine. Yet must he follow his ideal with no divided affections. The work of his profession must be his life-work—to be pursued with whole-hearted devotion to the last day of his life. Nor is the chance denied to the most remote and humble follower of medicine of contributing some fresh discovery or observation of value to the sum total of medical achievement. We have but to remind ourselves that some of the great things in medicine have come from country practitioners.

The Approach of Cholera.

Cholera is markedly on the increase in Russia. It has taken the usual course, and is mounting up the Volga, leaving a train of victims in its rear. That important centre, Nijni Novgorod, has now been invaded, fifty-five cases, with seventeen deaths, being reported there within the last few days. Nijni Novgorod is a large trading centre, and there is constant communication between it and Germany, so that the authorities in the latter country have naturally taken alarm, and rigid inspection of travellers is taking place at the frontier. Inspection, however, in the case of cholera, is not of much service, as the germs of the disease may be latent in a person in apparently good health, but who may rapidly become a source of extreme danger to others. Now that communication between India and Russia is being opened up more freely, the chances of the dissemination of cholera are correspondingly increased, and it may be expected as almost a normal autumnal event in the future for the disease to pass into South-East Europe. Probably, however, the outbreaks, although more frequent, will not attain the terrible proportions of the epidemics of 1869 and 1892, which created such havoc in European countries, and this country is certainly safe this year from any risk of serious incursion. On the other hand, however, while India remains the endemic centre of cholera, it will be one of the burdens of the Empire to seek to limit the excursions of the disease, and its rulers must, among their other troubles, seek to grasp the enormous responsibility that rests on them in the matter.

CURRENT TOPICS.

Public Health in Ireland.

The complacency with which the various public bodies, charged with the control of public health in Ireland, regard their own petty actions would be amusing were it not tragic. With urban death-rates among the highest in Europe, with infantile mortality out of all relation to the occupation of the people, with tuberculosis decimating the youth of the country, every sanitary authority persistently plumes itself on its energy and efficiency. In a debate in the Dublin Corporation, last week, we find a Mr. Clancy boasting that "out of chaos was evolved a city that they were all proud of. Out of a city of dirt and squalor and filth there had been produced a city that they were not ashamed to have people visiting." We fear it is true that Mr. Clancy and his friends are not ashamed that the death-rate in Dublin County Borough last year was 25 per 1,000, that the streets of the city are the filthiest of any city in the Kingdom, that every branch of sanitary work is neglected. If shame were felt at these things, there would be more hope of improvement. It is not the election bodies alone, however, which are to blame. The Local Government Board, whose duty it is to lead and advise the local bodies, is as boastful as Mr. Clancy and as inert as the meanest district council. Their representatives at a conference concerning tuberculosis a week or two ago declared proudly that the Local Government Board was fully awake to the serious nature of the tuberculosis problem. The evidence of their wakefulness was the issue of their circular during the course of the past thirty-six years'. In 1906, 11,756 persons died in Ireland of tuberculosis.

PERSONAL.

Dr. William Ewart will deliver the annaul inaugural address at St. George's Hospital, on Tuesday, Oct. 1st, the subject being "Res Medica, Res Publica." The annual dinner will be held at 7 p.m., the same evening, at the Whitehall Rooms, Hotel Metropole.

Colonel P. H. Benson, I.M.S., has been appointed Principal Medical Officer of the Secunderabad Brigade.

Professor Osler, M.D., F.R.S., will give the introductory address at St. Mary's Hospital Medical School on October 2nd.

The Volunteer Decoration has been awarded to Surgeon-Major C. A. MacMunn, 3rd (Vol.) Battalion of the South Staffordshire Regiment, and to Surgeon-Major George Hollier, 2nd (Vol.) Battalion of the Shropshire Light Infantry.

Miss Alice Brunton, daughter of Sir Lauder Brunton, has been awarded the diploma of Officier de l'Instruction Publique by the French Minister of Public Instruction, in recognition of her services to the late International Congress on School Hygiene.

Dr. D. Newman, Dr. D. C. McVail, Dr. J. C. Renton, Dr. D Macartney, and Dr. James Barras have been appointed medical referees for Lanarkshire under the Workmen's Compensation Act, 1906.

By the retirement of Colonel James Magill, M.D., C.B., the Royal Army Medical Corps will be deprived of the services of a most capable officer, whose many years of good work in Egypt and the Transvaal and other parts of the world, has been highly appreciated.

We have much pleasure in recording the rescue of a lady from drowning by Dr. Alfred Walker. The incident occurred at Port Gaverne, in Cornwall, and Dr. Walker, who was bathing at the time, pluckily proceeded to the spot where the lady sank and succeeded in bringing her to shore

By the will of the late Mr. William Marsh, the West Bromwich District Hospital has benefited to the extent of £1,000, while the Birmingham General Hospital and the Queen's Hospital, Birmingham, receive £350 each.

On September 5th the Ashton Board of Guardians passed a resolution viewing with surprise and alarm the utilisation by the Corporation of the isolation hospital for the treatment of so highly infectious a disease as scarlet fever, having in view the close proximity of the workhouse!

The will of the late Sir William T. Gairdner has been proved at £11,255, of which £2,604 were derived from insurance policies.

EDUCATIONAL SUMMARY FOR 1907-8.

INTRODUCTORY REMARKS.

If the pursuit of medicine is judged by the sneers of latter-day cynics like Bernard Shaw, or the bludgeon-blows of literary aliens like Maartens Maartens, it would appear to be a particularly mean and sneaking method of extracting coin out of the pockets of wealthy fools. But these gentlemen and others of their kidney have little title, as far as we can gather, to formulate indictments against a profession with whose members and whose work they must be strangely unfamiliar. Superior persons who wish to impress their generation with an idea of their transcendent perspicacity find a short and easy method of doing so to consist in sweeping all the dirt they come across into one corner of a room, and pointing to that as a sample of the condition of the floor. A better and more effective method of arriving at the true estimation in which a calling is held is to apply to the average man, who lives an average life, and has no wish to twinkle in the literary firmament as a star of the first order. It may pretty safely be laid down that the average man looks to his doctor not only as a trusty counsellor, but as a particularly good friend in time of trouble, and the practical reliance of such a man on his medical adviser is a better testimony to the latter's worth than all the problem-plays and six-shilling novels of a lustrum. It is a fact, and one worth noting, that in ordinary middle-class and upper middle-class society a medical man is not only always sure of a cordial reception, but he is always regarded among his patients as a peculiarly intimate friend, and one whom they are especially pleased to honour. Now, inasmuch as a medical man has no ready-made position of authority such as has a clergyman, nor the prestige of one of the destructive professions, such as the army or navy, nor the prospect of wealth that may be garnered from business, but simply his own attainments and personality to rely upon, it follows that the calling of medicine must attract men of higher potentiality than other lines of life, and endow them with an unusual degree of urbanity and kindliness, for them to attain such a position as we have indicated. If the ordinary general practitioner were possessed merely of a technical knowledge of bodily ailments, he might find rank and comradeship proportioned to his special attainments, but he would not gain that all-round respect or friendliness which is undoubtedly his. The cause for this social estimation lies largely in the humanising influence that the practice of medicine exerts on its followers; the knowledge of men and women at their best and at their worst, a knowledge which fails to make doctors cynics, but succeeds in making them sympathetic friends. They know how much may reasonably be expected of human nature, and are not soured with mankind when they find the popular general on his sick-bed wincing before the scalpel, the philanthropic peer grumbling at the flavour of his medicine, the anti-vaccinationist tub-thumper slinking round after dark to have the poisoned lymph inoculated in his arm, or the blatant anti-vivsectionist begging for antistreptococcic serum when he has a cut on the finger. All these things come in his day's work, and he early learns that disillusionment is a matter for happy mirth rather than for acid sarcasms on his fellows and their shortcomings. Moreover, his work soon shows him more clearly than that of anyone else where true valour and real goodness are to be found. He knows that the plucky little mother who labours for her family of six, and wears a perpetual smile, is never free from pelvic trouble that no one guesses at, and he knows that the shuffling shopman, whose clumsiness excites the ire of his customers, is making a brave struggle not to let his mitral disease break up the business he has put together himself. In the doctor's view of life the mother and the shopman more than outweigh the shrinking general and the testy lordling. The reward of the medical man's work and the pleasure of his existence is to be measured, then, by the benignity he acquires as he grows older, and certainly not by his balance, if balance there be, at the banker's. The man who sets out in practice with the intention of making a fortune and "founding a family" is rapidly undeceived; the conditions of work and its remuneration leave no scope for such tokens of worldly success. If, through a happy combination of private means, professional success, and influential friends he finds himself attached to the Court and the recipient of a baronetcy, the highest external honours available for a medical practitioner will have been attained, but he will figure but ignominiously in the eyes of society when he sits down to dinner with an Archbishop, a Lord Chancellor, a Field Marshal, a belted brewer, and a bacon king. In fortune, in influence, in importance in the councils of the State, the medical man can compare with none of these.

Let him make his goal, then, the accomplishment of small things and the advancement in the degree nearest his hand of the sum-total of medical knowledge. Let him seek to be an accomplished and resourceful practitioner, willing and able to lend a hand at any time and place to the sick and sorry, and to his brother practitioner; aiming at making an honest livelihood through upright and sturdy methods, and not hoping what he can never expect, namely, to rise to dignities and honours which are reserved for other callings than that of tending the sick.

CHOICE OF A SCHOOL.

The first decision that a student has to make, once he has irrevocably mated himself to the study of medicine, is as to where he shall carry out his intention. He would indeed be ungrateful if he grumbled that a wide enough choice was not provided for him, for with fifteen or sixteen Universities in the British Isles, many of them provided with several constituent schools, surely only a misanthrope could complain that his tastes, wishes, and predilections were not catered for. As practically all these Universities and schools are badly off for money, and not too rich in students, he may calculate on finding himself welcomed wherever he finally decides to go, which is indubitably an advantage at the outset of a career. There is, as a rule, a certain tendency for a man to look to his immediate vicinity for the maturing of his genius, and in these days, when Universities are cropping up with bewildering prolixity, most students will probably find one within fifty or sixty miles of their homes. As the medical curriculum is laid down carefully by the General Medical Council, there is not much variation in that of the individual schools, and a good all-round education can be relied on in practically every one. On the other hand, some have teachers of established ability and reputation, whilst others are seeking to obtain that enviable notoriety, and while some men may be attracted by the spirit of adventure to cast in their lot with the new and struggling, others will prefer the security of well-trodden paths. The object of this number of The Medical Press and Circular is to present impartially the claims and attractions of all schools, and if parents and their wards study its pages carefully they will, we feel sure, be convinced that there are none that have not their own special charms. The outlay on actual necessary educational expenses does not differ very materially in different places, the higher cost of certain centres being chiefly due to the greater cost of living. It is obvious that in London, for instance, where rents are high, the cost of lodgings must be considerably more than in many smaller and less favourite towns, while, on the contrary, a student living in his parents' home in London will not be so much expense to them if he goes to a London Hospital as if he takes up his abode at a northern university. But, other things being equal, it is a most important point for the average student to choose that school at which he is most likely in after years to obtain a resident post, and in this vital respect some of the less fashionable schools can present much greater advantages to the average man than can their more popular rivals.

Choice of Qualifications.

In a millennial state the question of the choice of qualifications will not arise, as every man will either be a doctor or not a doctor, without further ado. It so happens, however, that in the course of ages, among the anomalies surrounding the practice of the art of medicine, there have grown up a number of rival interests, both pecuniary and scholastic, which it is very difficult to break down, with the result that students are offered all sorts of qualifying diplomas, conferring on them the right to append almost every conceivable alphabetical combination to their names. It may be laid down in general terms that the shortest and least picturesque of these designations will generally be found the most serviceable, both from the expenditure of time that it will save in signing certificates, and in the greater ease by which it will be understanded of the people. Happily, or unhappily, a qualification even of the highest order has, as a rule, but small relation to success in practice, and many practitioners of light and leading will be found to have laid the foundations of their success on a more solid basis than that of academical triumph. The degree of M.D. of a British university should be the ordinary hall-mark of a British practitioner as much as a native M.D. is of his American *confrère*, but while those holding such a degree consider their market value would be lowered by its being "cheapened," the south countryman will be placed at a certain disadvantage as compared with his northern rival.

Course of Study.

Although there are certain individual variations, the course of study pursued at all the medical schools is pretty much the same. One or two of the universities are a little exacting in the number of special subjects they pile on to the crouching backs of their alumni, but in course of time it is generally found that the other centres of instruction follow their lead. Still, it is well to remember that from the moment the student pays his fee to the dean the disposition of each moment of his time for the next five years has been laid down with procrustean exactness, and that any diversion in the shape of amusement, illness, or failure in examination connotes a corresponding addition to the length of his pupilage.

Choice of Career.

The freshly-qualified man has the world open before him, and he may content himself with the reflection that his skill will be of as much service in Greenland's icy mountains as on India's coral strand, and he can ply his art with as beneficent results, though not with equal financial advantage, in Bethnal Green as in Grosvenor Square. He can therefore consult his predilections in some degree as to where he will practise his profession, though he will probably find the choice somewhat narrowed by the pecuniary resources at his disposal and the meagre opportunities offered for enterprise in the vicinity of popular, established practitioners. If he be averse from the struggle for existence in the troubled waters of private practice, he may turn to the comparative haven of competency afforded by the services. The Army, Navy, Indian, Colonial, and West African appointments may tempt him abroad, or the poor-law infirmaries, lunatic asylums, public health officerships, or fever hospitals may prevail on him to remain at home. In all the official Government services there is a career, even if a limited one, with graduated promotion and certain pension, whilst in the local services at home promotion is very uncertain, the pay, except in a few instances, very poor, and a pension either not provided or calculated on a studiously thrifty basis. One of the special advantages of medicine is that its votaries are nearly always sufficiently in request to be able to pick up a living as long as health lasts, but the prospects it affords of an old age of dignity and ease earned by professional diligence alone are somewhat dim.

Summary.

Medicine, then, may be recommended chiefly to those who have a strong turn for prying into the hidden things of nature, and find great pleasure and refreshment in so doing. To such the profession of healing will offer numberless opportunities for applying their peculiar powers, and will give much entertainment by the elusiveness of its secrets. The other class of man who finds satisfaction in the practice of medicine is he who regards the welfare of others before his own comfort and convenience. These rare beings, less rare probably in the medical profession than in any other, make devoted practitioners among the poor, and do not account their labour wasted if their patient gets well but cannot afford through stress of his illness to pay his bill. The man who does not get on well at medicine is he who wishes to account for all his services on a cash basis, and to make his practice a purely business concern. As a matter of fact it is not possible to translate personal services into an exact money equivalent, and much unpleasantness pursues the path of him who tries to do so. The best that many men hope for is that a reasonable number of honest and grateful people will be found so far to appreciate his services that he is relieved of financial strain for the next half-year. Those who make ample incomes in medicine are few, and the rush only lasts a few years. The man who enters the medical profession as a path to fortune is by way of being disappointed, though he who seeks an honourable competency has a fair chance of obtaining it.

THE ENGLISH UNIVERSITIES.

The English Universities are nine in number, *viz.*, Oxford, Cambridge, London, the Victoria, Durham, Liverpool, Leeds, Sheffield and Birmingham. The choice of a University is usually determined by social, geographical, and financial considerations. Students whose parents are able and willing to incur the necessary expense will do well to select one of the ancient Universities, since their degrees confer upon their holders a status not accorded by the public to the degrees of more modern institutions. To those less favoured by fortune, but blessed with energy and a fair share of intelligence, the London

University offers ample scope, and its degrees are recognised as the outward and visible sign of high professional attainments. A capable and industrious student, however, may equally well lay the foundations of success in one of the newer provincial Universities.

OXFORD.

There are two degrees in medicine, B.M. and D.M., and two degrees in surgery, B.Ch. and M.Ch. The B.M. and B.Ch. degrees are granted to those members of the University who have passed the second (B.M.) examination. Graduates in Arts, B.A., are alone eligible for these degrees. In order to obtain the degrees of B.M. and B.Ch., the following examinations must be passed:—1. Preliminary: Subjects:—Mechanics, and Physics, chemistry, zoology, and botany. 2. Professional (*a*) First examination (held twice a year): Subjects:—Organic chemistry, unless the candidate has obtained a first or second class in chemistry in the Natural Science School; Human physiology, unless he has obtained a first or second class in animal physiology in the Natural Science School; Human anatomy; Materia medica with pharmacy. (*b*) Second examination: Subjects:—Medicine, surgery, midwifery, pathology, forensic medicine with hygiene. The approximate dates of the examinations are as follow:—Preliminaries:—Physics, chemistry, and botany, December and June; Zoology, March and June; Professional (First and Second B.M.), June and December.

The degree of D.M. is granted to Bachelors of Medicine of the University who have entered their thirty-ninth term on presenting a dissertation approved by the appointed professors and examiners.

The degree of M.Ch. is granted to Bachelors of Surgery of the University who have entered their twenty-seventh term, who are members of the surgical staff of a recognised hospital, or have acted as dresser or house surgeon in such a hospital for six months, and who have passed an examination in surgery, surgical anatomy, and surgical operations. This examination is held annually, in June.

Diploma in Public Health.—The examination for the Diploma is held about the end of November in each year, and is open to any registered medical practitioner, whether he be a graduate of the University of Oxford or not. It is conducted according to the statutes and regulations of the University, and these have been framed so as to be consonant with the Resolutions and rules adopted by the General Medical Council for Diplomas in Public Health.

There are many valuable prizes and scholarships, details of which may be obtained from the University Calendar.

The examination consists of two parts. In the first of these candidates are required to exhibit a knowledge of chemistry and physics in the relations of these sciences to Public Health. In the second part of the Examination the candidate is examined in the subjects of general hygiene and of pathology in its bearings on Public Health. In all the subjects the Examination is partly practical. Candidates may offer themselves for the two parts of the examination on the same occasion or on different occasions; but their admission to the second part is contingent on their having already satisfied the examiners in the first part.

Candidates who desire to prepare for the examination within the University will be afforded facilities for doing so in the laboratories of the scientific departments concerned with the subjects of examination; and arrangements can also be made for candidates to acquire a practical knowledge of the duties of Public Health administration under the supervision of the Medical Officer of Health for the City of Oxford. Information on these points may be obtained by application to the Regius Professor of Medicine, University Museum, Oxford.

UNIVERSITY OF CAMBRIDGE.

At the University of Cambridge five years of medical study are required for the M.B. and B.C. degrees. The candidate must have resided nine terms (three years) in the University, and have passed the "previous" examination in classics and mathematics. There are three examinations: The first in (1) chemistry and physics, and (2) biology; the second in human anatomy and physiology; and the third in (1) pharmacology and general pathology, (2) in surgery, midwifery, and medicine. The first and the third examinations are divided into two parts, which can be taken separately. Subsequently to the third examination an Act has to be kept which consists in reading an original thesis, followed by an oral examination on the subject of the thesis. As the subjects for the examination for the degree in surgery are included in the third examination for the M.B. degree, candidates are admitted to the degree of Bachelor of Surgery on passing the third examination for Bachelor of Medicine.

The M.D. degree may be taken three years after the M.B. An Act has to be kept, including the presentation of an original thesis, with oral examinations and an essay to be written extempore. There is also the degree of Master of Surgery, for which the candidate, having already passed for B.C., or being M.A. has otherwise qualified in surgery, has to pursue extra study in surgery, and has a special examination or submits original contributions of merit to the science or art of surgery. The yearly expenditure of a student who keeps his term by a residence in a college is from £150 to £200 a year. This, however, may include all payments to the University and the College—all fees as well as clothes, pocket money, travelling expenses, &c. Non-collegiate students have only to pay the University fees, which are not large. They lodge and board as they like; their expenses, therefore, are entirely in their own hands.

The University grants a diploma in public health without the necessity of residence, the examination being in so much of State Medicine as is comprised in the functions of officers of health, and subject to the latest requirements of the General Medical Council. These examinations are held in Cambridge the first week in April and October. Candidates, whose names must be on the "Medical Register" of the United Kingdom, and need not be members of the University, should send in their applications to the Secretary of the State Medicine Syndicate a fortnight in advance. Every candidate who has passed both parts of the examination to the satisfaction of the examiners will receive a testimonial testifying to his competent knowledge of the subjects comprised in the duties of a medical officer of health.

There is also a special examination in Tropical Medicine and Hygiene, held annually in August. It is open to qualified practitioners under certain conditions as to previous study and experience. Successful candidates receive a University Diploma.

An abstract of all Regulations may be obtained upon sending a stamped directed envelope to the Assistant Registrary, Cambridge. Full information is contained in the University Calendar.

UNIVERSITY OF LONDON.

The Medical Faculty grants the degrees of Bachelor of Medicine and Surgery, Doctor of Medicine and Master in Surgery. Under the new regulations the students are divided into "Internal" and "External." An internal student is one who has matriculated at the University and is studying in a school approved by that body, or under the teachers of the University. An external student is one who has adopted an alternative course of study. The regulations differ somewhat in their application to the two groups of students. We only propose to deal with them as they affect *internal* students, since the special information required by the others had best be obtained direct from the Registrar. Under no circumstances will a student be admitted to the final examination for a degree until at least five years have elapsed since matriculation or other examination entitling to registration as a medical student.[*]

---

[*] May obtain registration as Internal or External students on presentation of documentary evidence as to their condition and a payment of £2; Graduates of such British, Colonial, and foreign Universities as are approved by the Senate for that purpose, and those who have

The Matriculation Examination takes place thrice yearly—in January, June (or July), and September. Application for admission to it must be made on a special form about six weeks beforehand, and the candidate must have completed his 16th year at the date of the examination. Candidates must show a competent knowledge of five subjects, among which *must* be English and elementary mathematics.

The Preliminary Scientific Examination takes place twice in each year, in January and July, and consists of papers on inorganic chemistry, biology, and physics, and there will be a practical examination in each subject. Examiners will also be at liberty to test candidates *viva voce.* A student may present himself for examination in each of the three subjects, separately or in all at the same time. Part I. of this examination includes papers in inorganic chemistry, physics, and biology, with practical examinations; Part II. is an examination in organic chemistry. Six months must elapse after passing Part I.

The Intermediate Examination in Medicine will take place twice a year, January and July. Candidates must have passed the Preliminary Scientific Examination at least two years previously. The subjects of examination are Anatomy, Physiology and Histology, and Pharmacology, including Materia Medica. Candidates who have failed in one subject only at this examination may offer themselves for re-examination in that subject, if permitted to do so by the examiners. Three scholarships, one of the value of £40 in Anatomy, another of the same amount in Physiology, and one of £30 in Pharmacology may be awarded by the examiners to any candidate who has passed the whole of the examination at one time.

Provincial Examinations for Matriculation.—These examinations are appointed by the Senate from time to time upon the application of any city, institution, or college desiring to be named as a local centre for one or more examinations in London under the supervision of sub-examiners also appointed by the Senate. Candidates wishing to be examined at any centre must give notice upon their forms of entry to the Principal of the University. Besides the University fee a fee usually varying from £1 to £3 is charged by the local authorities and must be paid *at the local centre* before the commencement of the examination.

The Final M.B., B.S. Examination takes place twice a year, in October and May. No candidate is admitted to this examination unless he has completed the course of study prescribed in the schedule or in less than two academic years from the date of passing the Intermediate Examination in anatomy and physiology.

The subjects of the examination are Medicine (including Therapeutics and Mental Diseases), Pathology, Forensic Medicine and Hygiene, Surgery, and Midwifery and Diseases of Women. The subjects may be divided into two groups, one of which shall comprise Medicine, Pathology, Forensic Medicine and Hygiene; and the other Surgery, Midwifery and Diseases of Women. Either group may be taken first at the option of the candidate, or the groups may be taken together.

Doctor of Medicine.—The examination for the degree of Doctor of Medicine is held twice a year, in December and July. Every candidate must have passed the examination for the M.B., B.S., of this University. Candidates may present themselves for examination in one of the following branches: (1) Medicine, (2) Pathology, (3) Mental Diseases, (4) Midwifery and Diseases of Women, (5) State Medicine: and if they wish, may pass also in another branch at a subsequent examination. Candidates for Branches 1 to 4 who have taken honours at the M.B., B.S. examination in the subject in which they present themselves for the M.D. degree, or who, subsequently to taking the M.B., B.S., have conducted a piece of original work approved for the purpose by the University, or have had special experience approved by the University, may present themselves for the M.D. examination one year after taking their Bachelor's degree. Candidates in Branch 5 (State Medicine) must show that they have taken the degrees M.B., B.S. not less than two years previously, and that subsequently to taking those degrees they have had (1) six months' practical instruction in an approved laboratory; (2) six months' practical instruction from a medical officer of health, of which three must not coincide with the laboratory work, and three months' practice at a hospital for infectious diseases. The interval between passing the M.B., B.S. and proceeding to the M.D. State Medicine may be reduced to one year, subject to conditions corresponding to those affecting Branches 1, 2, 3, and 4.

Master of Surgery.—The examination for the degree of Master in Surgery will take place twice in each year, commencing on the same dates as the foregoing, and the general regulations already quoted with regard to the M.D. will practically apply to it, surgery being substituted for medicine. The examination will consist of (1) two papers on surgery (one of which may be a case for commentary); (2) an essay to be written on one of two subjects which may be selected from any branch of surgery; (3) two papers on surgical pathology and surgical anatomy; (4) a clinical examination; (5) operations on the dead body; (6) a *viva voce* at the discretion of the examiners. Competent knowledge in every subject of the examination must be shown in order to pass.

Fees.—For Matriculation, £2 for each entry. Preliminary Scientific Examination.—Part I: £5 for each entry to the whole examination, and £2 for each subject when less than the whole examination is taken at one time. Part II.: No fee for first entry, £2 for each subsequent one. Intermediate Examination.—£10 for each entry to the whole examination, and £5 for re-examination in one subject. M.B., B.S. Examination —£10 for each entry to the whole examination, and £5 for examination or re-examination in either group. M.D. and M.S. Examinations.—£20 for each entry.

This University has established centres for preliminary and intermediate studies at University and King's Colleges, and students who purpose taking the London degree should make themselves acquainted with the details attached to external and internal students. Information on these points may be had of the Academic Registrar, University of London, South Kensington.

UNIVERSITY OF DURHAM.

One diploma and six degrees in Medicine and Hygiene are conferred, *viz.*, the degrees of Bachelor in Medicine, Bachelor in Surgery, Master in Surgery, Doctor in Medicine, Bachelor in Hygiene, and Doctor in Hygiene, and Diploma in Public Health. These degrees are open to both men and women.

For the degree of Bachelor in Medicine (M.B.) there are four professional examinations. The subjects for the first are: Elementary anatomy and elementary biology, chemistry, and physics. For the second: Anatomy, physiology, materia medica, therapeutics, and pharmacology. For the third: Pathology, medical jurisprudence, public health, and elementary bacteriology; and for the fourth: Medicine, clinical medicine and psychological medicine, surgery and clinical surgery, midwifery, and diseases of women and children.

It is required that one of the five years of professional education shall be spent in attendance at the University College of Medicine and the Royal Victoria Infirmary, Newcastle-upon-Tyne. First and second year students (dating from registration) are not required to comply with the regulation regarding attendance on hospital practice. Candidates who have passed the First and Second Examinations of the University will be exempt from the First and Second Examinations of the Conjoint Board.

---

passed all the examinations required for a degree in those Universities, also women who have obtained Tripos certificates granted by the University of Cambridge, and women who have obtained certificates showing that, under the conditions prescribed by the Delegacy for Local Examinations at Oxford, they have passed the Second Public Examination of that University or have obtained honours in the Oxford University Examination for Women in Modern Languages, and students who hold the Scotch School Leaving Certificate, having passed on one and the same occasion, in the Higher or Honours Grade in all the subjects required by the regulations for the Matriculation Examination.

For the degree of Bachelor in Surgery (B.S.) every candidate must have passed the examination for the degree of Bachelor of Medicine of the University of Durham, and must have attended one course of lectures on operative surgery, and one course on regional anatomy. Candidates will be required to perform operations on the dead body, and to give proof of practical knowledge of the use of surgical instruments and appliances.

For the degree of Master in Surgery (M.S.) candidates must not be less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek or German. In case they shall not have passed in either of these subjects at the Matriculation Examination for the M.B. degree, they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M.S. They must also have obtained the degree of Bachelor in Surgery of the University of Durham, and must have been engaged for at least two years subsequently to the date of acquirement of the degree of Bachelor in Surgery in attendance on the practice of a recognised hospital, or in the naval or military service, or in medical or surgical practice.

For the degree of Doctor in Medicine (M.D.) candidates must be of not less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek or German. In case they shall not have passed in either of these subjects at the Matriculation Examination for the M.B. degree, they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they proceed to the higher degree of M.D. They must also have obtained the degree of Bachelor of Medicine of the University of Durham, and must have been engaged for at least two years, subsequently to the date of acquirement of the degree of Bachelor of Medicine, in attendance on the practice of a recognised hospital or in the naval or military services, or in medical or surgical practice.

Each candidate must present an essay which has been prepared entirely by himself, and which must be typewritten, based on original research or observation, on some medical subject selected by himself, and approved by the Professor of Medicine, and must pass an examination thereon, and must be prepared to answer questions on the other subjects of his curriculum, so far as they are related to the subjects of the essay.

For regulations for degrees in Hygiene and for the diploma in Public Health see Calendar 1907-8.

Candidates for any of the above degrees must give at least twenty-eight days' notice to the Secretary of the College of Medicine, Newcastle-on-Tyne. In the case of the M.D. (Essay) Examination, candidates must send in their essays six weeks before the date of the examination.

A new wing has been added to the College of Medicine to accommodate the departments of physiology and bacteriology. It also contains students' union rooms and gymnasium.

The New Royal Victoria Infirmary, containing 400 beds, was recently opened by H.M. the King. In the new infirmary adequate accommodation is provided for the study of the various special subjects, in addition to the ordinary clinical work. Practical midwifery can be studied at the Newcastle Lying-in Hospital. Opportunities for practical study are also afforded by the Dispensary, City Infectious Diseases Hospital, Eye Infirmary, and at the Northumberland County Lunatic Asylum.

There are various appointments open to students, whilst the scholarships available are numerous and of considerable value.

Fees.—(*a*) A composition ticket for lectures at the college may be obtained—1. By payment of 72 guineas on entrance. 2. By payment of 46 guineas at the commencement of the first sessional year and 36 guineas at the commencement of the second sessional year. 3. By three annual instalments of 36, 31, and 20 guineas, respectively, at the commencement of the sessional year. A Composition Ticket for the course of lectures and practical work of the first two years of the curriculum may be obtained by the payment of 40 guineas on entrance. (*b*) Fees for attendance on hospital practice: For three months' medical and hospital practice, five guineas; for six months, eight guineas; one year, twelve guineas composition fee in one payment, twenty-five guineas; or by three instalments at the commencement of the sessional year, *viz.*, first year, 12 guineas: second year, ten guineas; third year, six guineas; or by two instalments, *viz.*, first year, fourteen guineas; second year, twelve guineas. In addition, two guineas yearly up to three years must be paid to the Committee of the Royal Infirmary.

Residence can be had in a separate hostel for female students at moderate inclusive fees for board, &c., particulars of which and any other college information will be given on application to Prof. Howden, Secretary, University of Durham College of Medicine, Newcastle-on-Tyne.

MANCHESTER UNIVERSITY.

Candidates for degrees in medicine and surgery must attend classes in the University during at least two years.

The Degrees in the Faculty of Medicine are Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). All candidates for Degrees in medicine and surgery are required to pass the Matriculation Examination, or to have passed such other examination as may from time to time be recognised for this purpose by the University.

The subjects of the Matriculation Examination are—1, Latin; 2, mathematics; 3, mechanics; 4, English and history; 5, one of the following:—(*a*) French; (*b*) German; (*c*) Greek; (*d*) Italian; (*e*) Spanish; (*f*) any other modern language, permission to present which has been obtained from the Joint Matriculation Board. Notice of intention to present either Italian or Spanish must be given to the Secretary, Joint Matriculation Board, Manchester, before March 1st in each year.

Before admission to the Degrees of Bachelor of Medicine and Surgery candidates are required to send in the usual certificates of age and study as at the other Universities. All candidates for these Degrees must pass four examinations, and must have attended courses of both lectures and laboratory work.

The final examination is divided into two parts, which may be passed separately or on the same occasion, but the first part cannot be taken before the end of the third year, and the second part cannot be taken less than two years after passing Second M.B., or before the fifth year of medical study in accordance with the University regulations. The subjects of examination are as follows: 1, Pharmacology and therapeutics; 2, General pathology and morbid anatomy; 3, Forensic medicine and toxicology and public health; 4, Obstetrics and diseases of women; 5, Surgery, systematic, clinical, and practical; 6, Medicine, systematic and clinical, including mental diseases and diseases of children. Candidates may select as a first part of the examination two or three of the subjects 1, 2, and 3.

The certificates required from candidates at the Third and Final examinations are practically the same as for the Final examination at the London University, and only those who have previously passed the Second Examination are admitted to it. The regulations relating to the M.D. and Ch.M. Degrees can be obtained on application to the Registrar.

Fees.—Matriculation examination, £2. First Examination, £5; for any subsequent examination, £2. The fees for the Second Examination, for the Third and Final Examinations, and for the examination for the degree of Ch.M. are the same as for the First Examination. A fee of £10 is payable on the conferring of the degree of M.D., a fee of £5 on the conferring of the degree of Ch.M.

The Matriculation Examination is held in July and in September. The first M.B. and Ch.B. is held in June; also about the end of September. The second examination is held in December, or in January or March; the Final in July and March; the examination for Ch.M. in July only.

The medical school buildings, which include large laboratories, dissecting-rooms, library and reading-rooms, are on the most modern principles, and students wishing to engage in anatomical, physiological, or pathological research will find excellent opportunity for study in the complete and well-furnished laboratories. Hospital practice is taken out at the (a) Royal Infirmary, which contains 300 beds. The Cheadle Lunatic Asylum, St. Mary's Hospital, the Southern Hospital, and other special hospitals also afford teaching facilities of great importance.

The appointments open to students are numerous and of considerable monetary value, and there are probably more here than are available at any other medical centre. The principal are:—Nine Entrance scholarships, the Leech fellowship of £100; Entrance scholarships in medicine, £100 (towards College and Infirmary fees); Manchester Grammar School scholarships, two or three of not less than £15 or more than £30 per annum for three years; Turner scholarship of £20 to students who have completed a course of medical study in the University; Platt physiological scholarships, two of the value of £50 each; Platt zoological and botanical scholarship, £50; Professor Tom Jones' memorial surgical scholarship of £100, awarded triennially; two Dauntsey medical entrance scholarships, value £35; John Henry Agnew scholarship in diseases of children, value £30, awarded annually; Graduate scholarship in medicine, £25 to £50, awarded annually; and many others.

Fees.—Composition fee, 83 guineas, in three instalments of 23, 30 and 30 guineas. Hospital practice: Composition fee, £42, or two instalments of £22 each.

Dental Fees.—Composition fee, £60, payable in two sums of £30 each. Hospital practice, £21.

UNIVERSITY OF BIRMINGHAM.

The University of Birmingham grants Degrees of M.B., Ch.B., M.D., Ch.M., and also a B.Sc. in the subject of Public Health. As a rule, in order to obtain any of these Degrees it is necessary that a student shall have passed at least the first four years of his curriculum in attendance upon the classes of the University, but the Senate has power of recognising attendance at another University as part of the attendance qualifying for these degrees.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—The student must have passed either the Matriculation Examination of the University or one of the following examinations, which will be accepted in lieu thereof for the present:—(*a*) The previous examination of the University of Cambridge; (*b*) Responsions of the University of Oxford; (*c*) The matriculation examination of any other University in the United Kingdom; (*d*) The leaving certificate (higher) of the Oxford and Cambridge Boards; (*e*) The Oxford or Cambridge junior local examination (first or second class honours); (*f*) The Oxford or Cambridge senior local examination (honours).

Matriculation Examinations are held in June and September each year.

Degrees of Doctor of Medicine and Master of Surgery.—At the end of one year from the date of having passed the Final M.B., Ch.B. Examination, the candidate will be eligible to present himself for the higher Degrees of either Doctor of Medicine or Master of Surgery or both, the regulations for which may be had upon application to the Dean. The University also grants a Degree and a Diploma in Public Health, and provides adequate instructions for the same.

Dental Department.—The University grants the Degrees of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.), and a Diploma in Dental Surgery (L.D.S.). The whole of the instruction for which may be taken out in the University, with which is associated the Birmingham Dental Hospital.

The General and Queen's Hospitals.—The practices of these hospitals are amalgamated for the purpose of clinical instruction under the direction of the Birmingham Clinical Board, by whom all schedules will be signed and all examinations conducted. The hospitals have a total of upwards of 450 beds. 8,000 in-patients and 80,000 out-patients are treated annually, and many valuable posts are open to students at both.

Further information can be obtained from Professor Gilbert Barling, Dean, Medical Faculty.

THE UNIVERSITY OF LIVERPOOL.

The Degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The course of study for the Degrees of Bachelor of Medicine and Bachelor of Surgery is of five years' duration, and of this period two years must be spent at the University, the remaining three years can be taken in any medical school approved by the University.

For the Degree of M.D., a thesis is required which may be presented not earlier than one year after graduation, as M.B., Ch.B.

The degree of Ch.M. is given after a period of at least one year of further study after graduation as M.B., Ch.B., on the results of an examination.

Diplomas.—Diplomas have been instituted in Public Health (D.P.H.), Tropical Medicine (D.T.M.), and Veterinary Hygiene (D.V.H.). Special diplomas are also granted in Anatomy, Bacteriology, Bio-chemistry, and Parasitology after a course of study of three terms in the subject chosen and allied subjects.

Students may enter for the degrees of the University of Liverpool, or may study for the degrees, diplomas and qualifications of the other licensing bodies.

Hospitals.—The Clinical School of the University now consists of four general hospitals—the Royal Infirmary, the David Lewis Northern Hospital, the Royal Southern Hospital, and the Stanley Hospital; and of five special hospitals—the Eye and Ear Infirmary, the Hospital for Women, the Infirmary for Children, St. Paul's Eye and Ear Hospital, and St. George's Hospital for Skin Diseases. These hospitals contain in all a total of 1,127 beds. The organisation of these hospitals to form one teaching institution provides the medical student and the medical practitioner with an unrivalled field for clinical education and study, and all are within easy access from the University. The period of hospital practice extends over the last three years of medical study. During the first two years no student will be permitted to change his attendance from one general hospital to another except at the commencement of an academic term. It is a regulation of the school that not more than five of the six terms of these two years shall be spent at any single General Hospital. During the final year of hospital practice a student is permitted to attend the practice of all the general hospitals without restriction. The regulations demand only that his attendance shall be regular and to the satisfaction of the Hospital's Board. There are a large number of appointments to House Physicianships and Surgeonships both at the general and special hospitals, which are open to qualified students of the School. These appointments (20) in most cases carry salaries varying from £60 to £100 per annum.

Fellowships and Scholarships.—Fellowships, Scholarships, and Prizes of over £800 are awarded annually. A Holt Fellowship in Pathology and Surgery, of the value of £100 for one year, is awarded annually by the Medical Faculty to a senior student possessing a medical qualification. The successful candidate is required to devote a year to tutorial work and investigation in the Pathological department. A Holt Fellowship in Physiology, awarded under similar conditions, also of the value of £100 for one year. A Robert Gee Fellowship in Anatomy, awarded under similar conditions, of the value of £100 for one year. An Alexander Fellowship for Research in Pathology of the annual value of £100, renewable. A Johnston Colonial Fellowship in Pathology and Bacteriology (£100 a year, renewable). A John W. Garrett

---

(*a*) **A new Infirmary is in course of erection, within a few minutes' walk from the University, which, when complete in 1908, will contain all the latest improvements of modern times.**

International Fellowship in Physiology and Pathology (£100 a year, renewable). An Ethel Boyce Fellowship in Gynæcological Pathology (£100 a year, renewable). A Stopford Taylor Fellowship (£100 a year, renewable) in Dermatological Pathology. A Thelwall Thomas Fellowship (£100 a year, renewable) in Surgical Pathology. A scholarship in Surgical Pathology (£50 a year renewable). Two Lyon Jones scholarships, of the value of £21 each for two years, are awarded annually—a Junior Scholarship, open at the end of the first year of study to Liverpool University students in the subjects of the first M.B. Examinations, and a Senior Scholarship, open to all students in the school at the end of the second or third year of study, in the subjects of Anatomy, Physiology, and Therapeutics. The Derby Exhibition of £15 for one year is awarded in Clinical Medicine and Surgery in alternate years. Students may compete in their fourth and fifth years. In 1908 the subject will be Clinical Surgery. The Torr Gold Medal in Anatomy, the George Holt Medal in Physiology, the Kanthack Medal in Pathology, and the Robert Gee Book Prize, of the value of £5, for Children's Diseases.

Entrance Scholarships.—Two Robert Gee Entrance Scholarships, of the annual value each of £25 for two years, are offered annually for competition. The holder is required to take out the First M.B. Course for the University Degree in Medicine.

The University also grants a Diploma in Dental Surgery (L.D.S.) and Degrees in Dental Surgery (B.D.S. and M.D.S.) The courses of systematic instruction are given in the University buildings, five minutes walk from the Dental Hospital.

Communications should be addressed to the Dean, Professor Benjamin Moore, M.A., D.Sc., the University, Liverpool.

Liverpool School of Tropical Medicine, and Diploma of Tropical Medicine, University of Liverpool.—The school is affiliated with the University of Liverpool and the Royal Southern Hospital of Liverpool. Three courses of instruction are given every year, commencing on January 14th, May 1st, and October 1st, and lasting for the academical term of about ten weeks. Each Course consists (1) of a systematic series of lectures on tropical medicine and sanitation delivered by the Professor of Tropical Medicine at the University; (2) of additional lectures on cytology, special African diseases and special Indian diseases delivered at the University; (3) of systematic lectures and demonstrations on tropical pathology, parasitology and bacteriology by the Walter Myers lecturer, at the University; (4) of similar instruction on medical entomology by the Lecturer on economic entomology at the University; and (5) of clinical lectures and demonstrations delivered at the Royal Southern Hospital by the Physician in charge of the Tropical Ward, the Professor, and the Walter Myers Lecturer. The instruction given occupies six hours a day for five days a week during the term. Teaching under headings 3 and 4 above is delivered in the Laboratory of the school at the University, which contains accommodation for thirty students with all necessary appurtenances, including a well-equipped museum, a class library, and access to the general departmental library. Teaching under heading 5 is given in the Tropical Ward, and the attached clinical laboratories of the Royal Southern Hospital on two or three afternoons a week.

At the end of each term an examination is held by the University for its Diploma of Tropical Medicine (D.T.M.), which is open only to those who have been through the course of instruction of the school. The examination lasts three days, and consists (1) of three papers on tropical medicine, tropical pathology, and tropical sanitation and entomology respectively; (2) of a clinical examination; and (3) of an oral examination. The results are declared as soon as possible afterwards. Those who do not wish to undertake the examination are given a certificate of attendance if their attendance has been satisfactory.

Accommodation for a limited number of students may be had at the Hall of Residence (for terms, apply to the Warden, 44 Upper Parliament Street).

The fee for the full course of instruction is ten guineas, with an extra charge of ten shillings for the use of a microscope, if required. The fee for the examination is five guineas. Applications should be made to the Dean of the Medical Faculty, University of Liverpool, from whom prospectuses may be obtained.

Two University Fellowships of £100 a year each are open to students of the school, amongst others. Accommodation for Research work is to be had, both at the University laboratory of the school, and at its Research Laboratories at Runcorn (sixteen miles distant from Liverpool).

Since it was instituted nine years ago the school has employed twenty-five different investigators paid out of its funds, and has despatched to the tropics seventeen scientific expeditions, many of the workers having been taken from among its students. The work done by them has been published in twenty-one special memoirs with many plates and figures, besides text books and numerous articles in the scientific press. From the beginning of this year, however, the Memoirs have been succeeded by the Annals of Tropical Medicine and Parasitology, published by the Committee, and open to outside contributors (apply to the Secretary, B10, Exchange Buildings, Liverpool). The Mary Kingsley Medal is awarded by the School for distinguished work in connection with tropical medicine, and has been given to Colonel Bruce, Professor Koch, Dr. Laveran and Sir Patrick Manson.

UNIVERSITY OF BRISTOL.

The lectures and instruction given in the Faculty of Arts and Science of University College, Bristol, are adapted to the various preliminary science examinations, and students can complete in Bristol the entire course of study required for the medical and surgical degrees of the University of London and the Royal College of Surgeons of England, and of the Apothecaries' Society of London. Well-equipped laboratories are now provided for anatomy, physiology, bacteriology, and pathology. Students of the college are admitted to the clinical practice of those very important and well-equipped institutions, the Bristol Royal Infirmary and the Bristol General Hospital. The infirmary and the hospital comprise between them a total of 470 beds, and both have very extensive out-patient departments, and special departments for the diseases of women and children, and of the eye, ear, and throat, besides large outdoor maternity departments and dental departments. Students of the college also have the privilege of attending the practice of the Bristol Royal Hospital for Sick Children and Women, containing 104 beds, and that of the Bristol Eye Hospital, with 40 beds. The total number of beds available for clinical instruction is therefore 614. Very exceptional facilities are thus offered to students for obtaining a wide and thorough acquaintance with all branches of medical and surgical work, and the whole curriculum is now open to women as well as men.

Appointments.—At the Royal Infirmary, and also at the General Hospital, clinical clerks and dressers reside in the house in weekly rotation. A pathological clerk is appointed every three months. Also obstetric clerks and ophthalmic dressers. Clinical lectures are given regularly at both institutions.

Scholarships, Prizes, &c.—Prizes and certificates of honour are given in University College in all the subjects of the curriculum. There are one medical entrance scholarship, value £75, awarded annually, two Martyn memorial scholarships (pathology and morbid anatomy) of £10 each, the Tibbits memorial prize, value £9, for proficiency in practical surgery, Henry Marshal prize, £12; Clarke Scholarship, £15; Sanders Scholarship, £22 10s.; one gold and silver medal awarded by the committee, and various prizes for clinical work in surgery and medicine.

Fees.—School fees for attendance on all courses of lectures and hospital practice, and including all fees, except vaccination and small charge for board of midwifery student, 133 guineas. If in two instalments, 80 guineas at first session and 60 guineas in the beginning of the second year. Dental composition fee, 75 guineas, including all lectures, practical classes, and hospital practice. Dental mechanical laboratory fee, 75 guineas. Clinical fees (if the composition fee has not been paid)—Surgical practice, one year, 12 guineas; perpetual, 20 guineas. Medical practice, 20 guineas; perpetual, medicine and surgery, 40 guineas.

Prospectus and further information on application to the Dean, Professor Edward Fawcett, M.D.

UNIVERSITY OF LEEDS.

The school of medicine attached to this recently incorporated University, was originally founded more than seventy years ago as the Leeds Medical School. The building, erected on a site contiguous to the infirmary, and opened twelve years since, contains one of the finest dissecting rooms in the Kingdom, extensive laboratories for physiology and pathology with the most recent improvements in fittings and apparatus, ample lecture-room accommodation, a large library, and separate museums for pathology and anatomy. Professors and lecturers are attached, and the clinical teaching is given by the physicians and surgeons attached to the Leeds General Infirmary, one of the largest in the United Kingdom, having 524 beds, with a staff of physicians and surgeons of considerable eminence. Ophthalmic demonstrations and demonstrations of skin diseases are given in the infirmary by surgeons in each department, where also are obtainable various clinical clerkships, dresserships, and other appointments; and an extern maternity charity is attached, at which the necessary attendance at labours can be taken, Besides the infirmary there is a large dispensary, a large hospital for infectious diseases, a hospital for women and children, and a maternity home, all of which are open to students of the school.

Scholarships, Prizes, &c.—(1) An entrance scholarship of £73 2s. 6d. There is also a Hardwick prize in clinical medicine, a M'Gill prize in clinical surgery, each of the value of £10. Thorp prizes of £10 and £5 in forensic medicine and hygiene, and a Scattergood prize of £5 in midwifery, besides silver and gold medals and other class prizes. The composition fee for attendance upon all the required courses of school lectures is £73 2s. 6d. for University students who have attended the preliminary scientific courses, and the same for non-University students, exclusive of chemistry and biology.

At the General Infirmary, the composition fee for medical and surgical practice and clinical lectures is £42 in one sum, or two instalments of £22 each. These fees are not included in the composition fees for lectures and are payable separately.

A scholarship of £42 to cover the cost of medical and surgical practice is offered annually by the Infirmary.

Degrees and Diploma in Dental Surgery are obtainable at this University, being Bachelor of Dental Surgery (B.Ch.D.), and Master of Dental Surgery (M.Ch.D.). Candidates for the degree of Bachelor of Dental Surgery are required to have passed the Matriculation Examination, to have pursued thereafter approved courses of study for not less than five academic years, two of such years at least having been passed in the University subsequently to the date of passing Parts I. and II. of the first examination, and to have completed such period of pupilage or hospital attendance, or both, as may be prescribed by the Regulations of the University. No candidate shall be admitted to the degree who has not attained the age of twenty-one years on the day of graduation.

Candidates for the diploma in Dental Surgery are required to present certificates showing that they have attained the age of twenty-one years, that they have attended courses of instruction, approved by the University, extending over not less than four years and that they have completed a pupilage of three years, two of such years at least, having been taken before the First Professional examination. Candidates are required to satisfy the Examiners in the several subjects of the following examinations: A preliminary examination in Arts; a Preliminary examination in Science; the First Professional examination; and the Final examination.

UNIVERSITY OF WALES.

The Cardiff School of Medicine, which is one of the colleges of the University of Wales, has since its foundation, in 1883, prepared students for the Preliminary Scientific Examination of the University of London, and for the corresponding examinations of other licensing bodies. In 1893 Chairs of Anatomy and Physiology and a Lectureship in Materia Medica and Pharmacy were established, making it possible for students of medicine to spend three out of the five years of prescribed study at Cardiff. Arrangements with the managing committee of the Cardiff Infirmary give students of the College the privilege of attending this large and well-ordered hospital, which is situated within five minutes' walk of University College. Many students, especially from Wales and Monmouthshire, avail themselves of the opportunities thus afforded to pursue the earlier part of the medical curriculum near home. All classes are open alike to both men and women students over sixteen years of age. The courses of instruction given at Cardiff are recognised as qualifying for the examinations of the Universities, Royal colleges, and other licensing bodies of Great Britain and Ireland. Having spent two or three years in study at Cardiff, and having passed the examinations in these years, a student may proceed to London or elsewhere and complete his qualifying course for a University degree or for a college diploma.

Students preparing for the first and second examinations of the Conjoint Board for England, or for the corresponding examinations of the Conjoint Board for Scotland, or for those of the Society of Apothecaries, may compound for their classes by paying a single composition fee of £41 10s., or by paying £20 and £24 10s. at the beginning of their first and second years respectively. Those preparing for the preliminary scientific and intermediate examination in medicine of the University of London may compound for their three years' instruction at Cardiff by paying a single composition fee of £57 10s., or by paying £13 13s., £28, and £21 at the beginning of their first, second and third years respectively.

In 1899 a department of Public Health was established, and lecturers in bacteriology and in public health and hygiene were appointed. Medical men preparing for a diploma in Public Health and Hygiene can attend complete courses of lectures and laboratory instruction in this department. These courses are recognised by the University of Cambridge, by the Royal Colleges of Physicians and Surgeons, and by Victoria University.

In the case of medical students, attendance on the class of hygiene and public health is accepted by the Universities of London and Cambridge, and by the Conjoint Examining Board of England

Courses of lectures to midwives, adapted to the requirements of the Central Midwives' Board, under the Midwives Act, are commenced in October, January, and April. The lectures are suitable both for pupil midwives and practising midwives, as well as for nurses who desire to enter for the examination for certification under the Act.

Scholarships, &c.—The attention of students about to matriculate is drawn to the numerous entrance scholarships and exhibitions which are offered at the college for competition in September, most of which may be held by medical students. Full particulars of the examination for these may be obtained from the Registrar, or from the Dean of the Medical Faculty.

UNIVERSITY OF SHEFFIELD.

By the Charter granted in 1905, this University is permitted to grant degrees in medicine. All its courses and all its degrees are open, without restriction, to both sexes. The new buildings of the University, opened by his Majesty King Edward in 1905, are situated at the west end of the city, overlooking on two sides the adjoining Weston Park. The medical department occupies the entire north wing of the University quadrangle, and is within easy reach of the various hospitals, with which it is connected for clinical purposes.

These are as follows:—The Royal Infirmary contains 255 beds, with an annual average number of over 3,800 in-patients, over 8,000 out-patients, and over 21,000 casualties; the Royal Hospital, with 165 beds, and an annual number of 2,500 in-patients, over 7,000 out-patients, and over 14,000 casualties; the Jessop Hospital for Diseases of Women, with 80 beds, nearly 500 in-patients, and over 2,000 out-patients; also a Maternity Department, with over 250 in-patients per annum, and over 700 out-patient cases attended. Special courses on fevers are held at the City Fever Hospitals (547 beds), and on Mental Diseases at the South Yorkshire Asylum (1,610 beds).

Clinical Practice.—The practices of the Royal Infirmary and Royal Hospital are amalgamated for the purpose of clinical instruction, giving a total of 420 beds for the treatment of medical, surgical and special cases.

Appointments.—The following are open to all students who have passed their examinations in anatomy and physiology:—Casualty Dresserships, Surgical Dresserships, Medical Clerkships, Pathological Clerkships, Ophthalmic Clerkships, Clerk to the Skin Department, etc.

Fees.—Composition fee of £80, payable in three instalments, viz.:—£24 at commencement of first year of study; £28 at commencement of second year of study; £28 at commencement of third year of study. This composition fee entitles the student to attendance on all the courses of lectures and practical classes, except pharmacy, vaccination, and instruction in anæsthetics required for a degree course in the University, or for the ordinary qualifications in medicine and surgery of the examining boards.

Composition Fee for Medical and Surgical Hospital Practice.—Fee for the full period of both medical and surgical hospital practice required by the examining boards:—If paid in one sum at commencement of hospital practice, £36 15s.; or if paid in two sums of £18 18s., one on beginning hospital practice, the other twelve months later, £37 16s.

Dental Department.—In connection with the University there is a complete dental department, which is fully recognised by the various examining bodies, and students are able to get their full curriculum here.

Scholarships and Fellowships.—Women's Medical Scholarship, value £100, open to women only; awarded in September, 1907. Entrance Medical Scholarship, value £116, open to both sexes, awarded in June in each year. Two Staff Medical Scholarships, each value £50; open to both sexes. One Town Trustees' Scholarship, value £50, tenable for three years, for girls under the age of 19 years. Two Town Trustees' Scholarships, value £60 each, for boys or girls under 19 years of age. Town Trustees' Fellowship, value £75, open to graduates of the University, tenable for one year. Mechanics' Institute Scholarship, value £50, tenable for one year, and renewable for a second year. The Frederick Clifford Scholarship, value about £50 per annum, tenable for two years, open to graduates of the University; and the Kaye Scholarship, value about £22 10s. Gold Medal offered annually for the best student in clinical medicine and clinical surgery. Bronze medals are awarded each year to the students who have gained first place in the examinations for the full course.

Degrees.—Candidates for a medical degree must have matriculated in the University or have passed such other examination as may be recognised for this purpose by the University and sanctioned by the Joint Matriculation Board. The subjects required by the General Medical Council must be included in the matriculation examination, or its recognised substitute. The degrees in medicine obtainable are Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.); conditions and particulars of which may be obtained on application to the Dean.

At the University of Sheffield post-graduate courses are held annually. The subjects vary from time to time, and include bacteriology, physiology, applied anatomy, surgery, operative surgery, ophthalmic surgery, diseases of ear and throat, dermatology, etc.

THE ENGLISH COLLEGES.

THE medical corporations in England are the Roya College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries of London. The two Royal Colleges now co-operate to hold a series of examinations, on passing which the candidate receives the diploma of Licentiate of the Royal College of Physicians (L.R.C.P.), and Member of the Royal College of Surgeons (M.R.C.S.). The Society of Apothecaries grants a complete diploma (L.S.A.) in medicine, surgery, and midwifery.

CONJOINT EXAMINING BOARD IN ENGLAND.

Candidates for the above licences are required to complete five years of professional study at recognised medical schools and hospitals, after passing the preliminary examination, of which six months may be spent at an institution recognised by the Board for instruction in chemistry, or one year may be passed at an institution recognised by the Board for instruction in chemistry and physics, to comply with the following regulations and to pass the examinations hereinafter set forth.

Professional Examinations.—There are three examinations, each being partly written, partly oral, and partly practical. These examinations will be held in the months of January, April, July, and October, unless otherwise appointed, fourteen clear days' notice before the day on which the examination commences being required, the candidate transmitting at the same time the required certificates.

The subjects of the first professional examination are chemistry and physics, practical pharmacy, and elementary biology. A candidate is allowed to take this examination in three parts at different times. Rejection entails a delay of not less than three months from the date of rejection, and the candidate will be re-examined in the subject or subjects in which he has been rejected. If referred in chemistry or biology, he must produce evidence of further instruction at a recognised institution. Practical pharmacy may be passed at any time during the curriculum. Any candidate who shall produce satisfactory evidence of having passed an examination for a degree in medicine on any of the subjects of this examination conducted at a University in the United Kingdom, India, or in a British Colony, will be exempt from examination in those subjects in which he has passed.

The fees for admission to the first examination are as follow:—For the whole examination, £10 10s.; for re-examination after rejection in Part I., £3 3s.; and for re-examination in each of the other parts, £2 2s.

The subjects of the second examination are anatomy and physiology. Candidates will be required to pass in both subjects at one and the same time. Candidates will be admissible to the second examination at the expiration of two winter sessions and one summer session (or fifteen months during the ordinary sessions) from the date of registration as medical students, and after the lapse of not less than nine months from the date of passing Parts I. and III. of the first examination.

A candidate referred at the second examination will be required, before being admitted to re-examination, to produce a certificate that he has pursued, to the satisfaction of his teachers, in a recognised place of study, his anatomical and physiological studies during a period of not less than three months subsequently to the date of his reference.

The fees for admission to the second examinations are: £10 10s. for the whole examination, and £6 6s. for re-examination after rejection.

The subjects of the third and final examinations are:—Part I. Medicine, including medical anatomy, pathology, practical pharmacy, therapeutics, forensic medicine and public health. Candidates who have passed in practical pharmacy at the first examination will not be re-examined in that subject at the third examination. Part II. Surgery, including pathology, surgical anatomy, and the use of surgical appliances.

Part III. Midwifery and gynæcology. Candidates may take this examination in three parts separately, or they may present themselves for the whole examination at one time.

Fees for admission to the third or final examination are as follow:—For the whole examination, £21 0s. Part I.—For re-examination in medicine, including medical anatomy, pathology, therapeutics, forensic medicine, and public health, £5 5s.; for re-examination in practical pharmacy (if taken at this examination), £2 2s. Part II.—For re-examination in surgery, including pathology, surgical anatomy, and the use of surgical appliances, £5 5s. Part III.—For re-examination in midwifery and gynæcology, £3 3s.

A candidate referred on the third or final examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and will be required, before being admitted to re-examination, to produce a certificate, in regard to medicine and surgery, of having attended the medical and surgical practice, or the medical or surgical practice, as the case may be, during the period of his reference; and in regard to midwifery and diseases peculiar to women a certificate of having received, subsequently to the date of his reference, not less than three months' instruction in that subject by a recognised teacher.

Regulations for Colonial, Indian, and Foreign Candidates, and University Candidates.

Persons holding a Colonial, Indian, or a foreign qualification entitling them to practise medicine in the country of origin, and conferred after a course of study and examinations equivalent to those required by the Royal Colleges, are admissible to the second and third (final) examinations forthwith.

Members of a University in the United Kingdom are, under certain conditions, eligible for admission to the third (final) examination two years after passing at their University in the subjects included in the first and second examinations of the Board.

Royal College of Physicians of London.

Members.—The membership of the College is granted after examination to persons above the age of 25 years who do not engage in trade, do not dispense medicine, and do not practise in partnership. This diploma is only granted to persons already registered, or who have passed the final examination for the licence.

Medical graduates of a recognised University are admitted to a pass examination, but others must have passed the examinations required for the licence of the College. The examination, which is held in January, April, July, and October, is partly written and partly oral. It is directed to medicine, and is conducted by the president and censors. Candidates under 40, unless they have obtained a degree in arts in a British University, are examined in Latin, and either Greek, French, or German. Candidates over 40 are not so examined, and the examination in medicine may in their case be modified under conditions to be ascertained by application to the Registrar. The fee for the membership is £42, but if the candidate is a licentiate £15 5s. is deducted. In either case £6 6s. has to be paid before examination.

Royal College of Surgeons of England.

Membership.—The candidates are now subject to the regulations of the Conjoint Board.

Fellowship.—The Fellowship of the College of Surgeons is granted after examination to persons at least 25 years of age, who have been engaged in professional studies for six years. There are two examinations—the first in anatomy and physiology, which may be passed after the third winter session; the second chiefly directed to surgery, which may be passed after six years of professional study. The second examination may be passed before attaining the age of 25, but the diploma is not granted until that age is reached. Candidates for this part of the examination must have passed the final examination of the Conjoint Board in England, and have been admitted members of the College before they can be admitted thereto, except in the case of graduates in medicine and surgery of recognised Universities of not less than four years' standing.

Fees.—First examination, £5 5s.; second examination, £12 12s. The total fee payable on admission to the Fellowship is £31 10s., except for members, when the fee is £21. (The examination fees to the extent of £17 17s. count as part of the total fee.) Further information can be obtained on application to the Secretary of the Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.

There are two examinations—primary and final. The primary examination is held quarterly on the first Wednesday, and on the Monday and Tuesday in the same week, in the months of January, April, July, and October. The final examination is held monthly.

Society of Apothecaries of London.

Primary Examination.—This examination consists of two parts: Part I.—Elementary biology, Chemistry, Chemical physics, including the elementary mechanics of solids and fluids; Heat, Light, and Electricity. Practical chemistry, Materia medica, and Pharmacy. A synopsis indicating the range of the subjects may be obtained on application. Part II.—Anatomy and Physiology and Histology. The examination is held in January, April, July, and October.

The final examination is held monthly, and is divided into Sections 1 and 2.

Section 1 consists of three parts.
